"To the solid ground
Of Nature trusts the mind which builds for aye"—WORDSWORTH

THURSDAY, NOVEMBER 4, 1880

THE FIRST VOLUME OF THE PUBLICATIONS OF THE "CHALLENGER"

FOUR years have elapsed since the *Challenger* returned from her famous cruise, and the scientific world has been looking, of late perhaps somewhat impatiently, for the first instalment of the long series of volumes which is to embody the results of the investigations of the best-equipped voyagers who ever left the shores of England for the purpose of enlarging the bounds of natural knowledge.

But this is one of the many cases in which impatience is more natural than justifiable In the "General Introduction" with which Sir Wyville Thomson prefaces the "Reports" which are to appear in the first volume of the great work for which he is responsible, he mentions that the zoological specimens collected and preserved in alcohol during the voyage filled 2270 large glass jars, 1749 smaller bottles, 1860 glass tubes, and 176 tin cases; while 22 casks and 180 tin cases held objects preserved in other ways.

In dealing with this vast mass of material, Sir Wyville Thomson justly considered it to be his duty to obtain, as far as it was practicable so to do, the co-operation of the best specialists in every department, irrespective of nationality; and it is gratifying to find that, in reply to his invitations, many foreign men of science of great distinction have willingly associated themselves with a strong corps of English workers. This matter being arranged, the specimens had to be distributed to their destinations; and the several workers, rarely men of much leisure, found themselves embarked in months or years of critical and laborious investigation. Along with this went the slow process of writing out the results, and the still slower of executing the illustrations with due care, all of which had to be finished before the printer could begin his operations.

To those who are familiar with the amount of expenditure of trouble and time which all these processes mean, it will seem no small matter that seven treatises, illustrated by a large number of admirably executed plates, are now ready for distribution, and that three more volumes of no less magnitude are to be issued before the end of the year, so that the fifteen or sixteen volumes of which the whole work is to consist may reasonably be expected to be in the hands of the public by 1884

The "Zoological Reports," as these separate treatises upon each group of specimens are termed, are printed as they are completed, and are to be issued, without reference to the order which they will eventually occupy, as soon as sufficient matter to form a volume is ready. Each memoir will be separately paged, and will have its own legend for reference. This arrangement has been adopted in order that working naturalists may have access to the "Reports" as early as practicable, and that the multiplication of synonyms by the simultaneous publication of species by different observers may be avoided With this object in view, it would perhaps have been even better to have issued every "Report" as it was ready, but it may be that there are practical difficulties in the way of the adoption of this course

The present writer, though a fairly swift reader, does not profess to have perused the seven elaborate memoirs now presented on behalf of the *Challenger*, nor if he had does he lay claim to that zoological omniscience which would justify him in criticising them in detail. But as Mr. Brady deals with the Ostracoda, Mr Davidson with the Brachiopoda, Dr Gunther with the Shore Fishes, Prof Kolliker with the Pennatulidæ, Mr Moseley with those groups of Corals which he has made his special study, Mr Parker with the Development of the Chelonian Skull, and Prof. Turner with the Cetacea, it is questionable if any extant finite knowledge is likely to enable its possessor to say anything more or better than they have said on these respective topics And, as has been already remarked, there can be no sort of doubt as to the artistic excellence of the 122 quarto plates which illustrate and adorn the text.

Sir Wyville Thomson's "General Introduction," however, is extremely readable both in size and in substance, and may be commended to that patient omnivore, the General Reader, who will find in its earlier pages a readily intelligible account of the fittings and appliances of the *Challenger*, and of the means by which the greatest depths of the sea have been made to yield some, at any

rate, of the secrets of the busy life which, contrary to all the beliefs of the naturalists of a past generation, blindly toils and moils in the darkness and cold of the marine abysses

The latter half of the "Introduction" will be no less interesting to the biologist, since it embodies the general conclusions at which the scientific director of the Expedition has arrived, in a dissertation on the nature and distribution of the fauna of the deep sea

Sir W Thomson considers that the most "prominent and remarkable biological result" of the four years' work of the *Challenger* is the final establishment of the fact "that the distribution of living beings has no depth-limit, but that animals of all the marine invertebrate classes, and probably fishes also, exist over the whole of the floor of the ocean." As to the exact nature of this deep-sea fauna at the greatest depths, he speaks with some hesitation; but, at about 2000 fathoms, the list given on pages 36 and 37 proves that there is a large and a varied assemblage of forms of life. Upwards, this characteristic deep-sea fauna extends to about 600 fathoms, and is richest between this depth and 1000 or 1200 fathoms Around all coasts, in temperate regions, the local shore forms, which occupy successive zones of depth as, on land, they characterise zones of height, gradually die out towards the 200-fathom line Nor is there any close relation between the abyssal and the shore faunæ of any given latitude or longitude—on the contrary, the abyssal fauna is singularly uniform and appears "to have been derived from a genetic source different from that of the shore fauna." In fact, Sir Wyville Thomson appositely compares the abyssal ocean—that is the sea everywhere below 200 fathoms or thereabouts—to a world-wide lake of comparatively still water, which, in its deeper parts, is very cold, its temperature neither rising nor falling appreciably beyond the average of 35° F.

Thus there is a certain parallel between land and sea distribution, inasmuch as all Alpine floræ present marked analogies with circumpolar floræ The cold land is discontinuous, whence it presents, as it were, islands of analogous population all over the world; while the cold water being continuous, the continuity in its population is correspondingly unbroken. But the uniformity and invariability of conditions is far more complete in the abyssal lake than on the mountain-tops, and the homogeneity of the population harmonises with that of the medium in which it lives.

Sir Wyville Thomson draws attention to the fact that this widespread abyssal fauna

". . . . has a relation to the deep-water fauna of the Oolite, the Chalk, and the Tertiary formations, so close that it is difficult to suppose it in the main other than the same fauna which has been subjected to a slow and continuous change under slightly varying circumstances according to some law, of the nature of which we have not as yet the remotest knowledge" (p. 49).

"There is every reason to believe that the existing physical conditions of this area date from a very remote period, and that the present fauna of the deep sea may be regarded as directly descended from faunæ which have necessarily occupied the same deep sea . . . That the present abyssal fauna is the result of progressive change there can be no room for doubt; but it would seem that in this case, the progress has been extremely slow, and that it has been brought about almost in the absence of those causes—such as minor and local oscillations of the crust of the earth producing barriers and affecting climate—on which we are most inclined to depend for the modification of faunæ. The discovery of the abyssal fauna, accordingly, seems to have given us an opportunity of studying a fauna of extreme antiquity, which has arrived at its present condition by a slow process of evolution from which all causes of rapid change have been eliminated" (p. 50).

That the deep-sea fauna presents us with many forms which are the dried and but little modified descendants of Tertiary and Mesozoic species is a proposition which few who attend to the evidence will be disposed to deny. But I may venture to express some doubt, whether it may not be well to keep a conclusion of such gravity and so well founded, apart from views respecting the absence of "minor local oscillations of the crust of the earth" in the area of the present great ocean basins, which Sir Wyville Thomson expresses more fully elsewhere.

"There seems to be sufficient evidence that all changes of level since the close of the Palæozoic period are in direct relation to the present coast lines.

"There does not seem to be a shadow of reason for supposing that the gently undulating plains, extending for over a hundred million of square miles, at a depth of 2500 fathoms beneath the surface of the sea, and presenting, like the land, their local areas of secular elevation and depression, and their centres of more active volcanic disturbance were *ever* raised, at all events in mass, above the level of the sea, such an arrangement, indeed, is inconceivable" (p. 46).

I must plead ignorance of the "sufficient evidence" to which Sir Wyville Thomson refers; in fact, I should have thought that the sufficient evidence lay in the other direction Surely there is evidence enough and to spare that the Cretaceous sea, inhabited by various forms, some of whose descendants Sir W. Thomson, as I believe justly, recognises in the present deep-sea fauna, once extended from Britain over the greater part of Central and Southern Europe, North Africa, and Western Asia to the Himalayas. In what possible sense can the change of level which has made dry land and sometimes mountain masses of nine-tenths of this vast area be said to be "in direct relation to the present existing coast lines"?

That the abyssal plains were ever all elevated, at once, is certainly so improbable that it may justly be termed inconceivable, but there is nothing, so far as I am aware, in the biological or geological evidence at present accessible, to render untenable the hypothesis that an area of the mid-Atlantic or of the Pacific sea-bed as big as Europe should have been upheaved as high as Mont Blanc and have subsided again any time since the Palæozoic epoch, if there were any grounds for entertaining it.

In concluding the "Introduction" Sir Wyville Thomson expresses "a strong personal impression" on two points. The one is that the study of the abyssal fauna lends a powerful support to the doctrine of evolution. The other is, that "the character of the abyssal fauna refuses to give the least support to the theory which refers the evolution of species to extreme variation guided only by natural selection" But the grounds assigned for the latter opinion are hardly so cogent as might be desirable.

"Species are just as distinctly marked in the abyssal

fauna as elsewhere, each species varying within its definite range as each species appears to have varied at all times past and present" (p. 50).

Exactly so; the abyssal species are like species elsewhere. The difficulties in the way of the application of the evolution of species by variation and selection therefore in this case cannot be greater than elewhere. In fact, from the sentences which end the "Introduction" it seems doubtful whether they are not less than in many other cases.

"Transition forms linking species so closely as to cause a doubt as to their limit are rarely met with. There is usually no difficulty in telling what a thing is" (p. 50).

Hence it appears that the study of the abyssal fauna has satisfied Sir Wyville Thomson that transitional forms are sometimes met with, and that, sometimes, he has found a difficulty in "telling what a thing is." And this admission is all that the most ardent disciple of Mr Darwin could desire.

However, the value of the great work which is now being brought before the public does not lie in the speculations which may be based upon it, but in the mass and the solidity of the permanent additions which it makes to our knowledge of natural fact. Sir Wyville Thomson and his colleagues must be congratulated on having made an excellent beginning, the looker-on may properly content himself with wishing them a speedy and a good ending.

T. H. HUXLEY

THE LAVA-FIELDS OF NORTH-WESTERN EUROPE

FROM the earliest times of human tradition the basin of the Mediterranean has been the region from which our ideas of volcanoes and volcanic action have been derived. When the old classical mythology passed away and men began to form a more intelligent conception of a nether region of fire, it was from the burning mountains of that basin that the facts were derived which infant philosophy sought to explain. Pindar sang of the crimson floods of fire that rolled down from the summit of Etna to the sea as the buried Typhoeus struggled under his mountain load. Strabo, with matter-of-fact precision and praiseworthy accuracy, described the eruptions of Sicily and the Aeolian Islands, and pointed out that Vesuvius, though it had never been known as an active volcano, yet bore unequivocal marks of having once been corroded by fires that had eventually died out from want of fuel. In later centuries, as the circle of human knowledge and experience has widened, it has still been by the Mediterranean type that the volcanic phenomena of other countries have been judged. When a geologist thinks or writes of volcanoes and volcanic action, it is the structure and products of such mountains as Etna and Vesuvius that are present to his mind. Nowhere over the whole surface of the globe have eruptions been witnessed different in kind though varying in degree from those of the Mediterranean vents. And hence even among those who have specially devoted themselves to the study of volcanoes there has been a tacit assumption that from the earliest times and in all countries of the world where volcanic outbreaks have occurred, it has been from local vents like those of Etna, the Aeolian Islands, the Phlegraean Fields, or the Greek Archipelago.

If one were to assert that this assumption is probably erroneous, that the type of volcanic "cones and craters" has not been in every geological age and all over the earth's surface the prevalent one, that, on the contrary, it is the less portentous, though possibly always the most frequent type of volcanic action, and belongs perhaps to a feebler or waning degree of volcanic excitement—these statements would be received by most European geologists with incredulity, if not with some more pronounced form of dissent. Yet I am convinced that they are well founded, and that a striking illustration of their truth is supplied by the greatest of all the episodes in the volcanic history of Europe—that of the basalt-plateaux of the north-west.

It is now some twelve years since Richthofen pointed out that on the Pacific slope of North America there is evidence of the emission of vast floods of lava without the formation of cones and craters. Geologists interested in these matters may remember with what destructive energy Scrope reviewed his "Natural System of Volcanic Rocks", how he likened it to the old crude ideas that had been in vogue in his younger days, and which a study of the classical district of Auvergne had done so much to dispel; and how he ridiculed what he regarded as "fanciful ideas" and "untenable distinctions," which it was "a miserable thing" to find still taught in mining-schools abroad. My own reverence for the teaching of so eminent a master and so warm-hearted a friend led me to acquiesce without question in the dictum of the author of "Considerations on Volcanoes." Having rambled over Auvergne with his admirable sections and descriptions in my hand, I knew his contention as to the removal of cones and craters by denudation and the survival of more or less fragmentary plateaux once connected with true cones to be undoubtedly correct with respect at least to that region. Nevertheless there were features of former volcanic action on which the phenomena of modern volcanoes seemed to me to throw very little light. In particular the vast number of fissures which in Britain had been filled with basalt and now formed the well-known and abundant "dykes" appeared hardly to connect themselves with any known phase of volcanism. The area over which these dykes can be traced is probably not less than 100,000 square miles, for they occur from Yorkshire to Orkney, and from Donegal to the mouth of the Tay. As they pierce formations of every age, including the Chalk, as they traverse even the largest faults and cross from one group of rocks into another without interruption or deflection, as they become more numerous towards the great basaltic plateaux of Antrim and the Inner Hebrides, and as they penetrate the older portions of these plateaux, I inferred that the dykes probably belonged to the great volcanic period which witnessed the outburst of these western basalts. Further research has fully confirmed this inference. There can be no doubt that the outpouring of these great floods of lava of which the hills of Antrim, Mull, Morven, Skye, Faroe, and part of Iceland are merely surviving fragments and the extravasation of these thousands of dykes are connected manifestations of volcanic energy during the Miocene period.

But this association of thin nearly level sheets of basalt piled over each other to a depth of sometimes 3,000 feet, with lava-filled fissures sometimes 200 miles distant from

them, presented difficulties which in the light of modern volcanic action remained insoluble. The wonderfully persistent course and horizontality of the basalts with the absence or paucity of interstratified tuffs, and the want of any satisfactory evidence of the thickening and uprise of the basalts towards what might be supposed to be the vents of eruption were problems which again and again I attempted vainly to solve. Nor so long as the incubus of "cones and craters" lies upon one's mind does the question admit of an answer. A recent journey in Western America has at last lifted the mist from my geological vision Having travelled for many leagues over some of the lava-fields of the Pacific slope, I have been enabled to realise the conditions of volcanism described by Richthofen and, without acquiescing in all his theoretical conclusions, to judge of the reality of the distinction which he rightly drew between "massive eruptions" and ordinary volcanoes with cones and craters. Never shall I forget an afternoon in the autumn of last year upon the great Snake River lava desert of Idaho. It was the last day of a journey of several hundred miles through the volcanic region of the Yellowstone and Madison We had been riding for two days over fields of basalt, level as lake bottoms, among the valleys, and on the morning of the last day, after an interview with an armed party of Indians (it was only a few days before the disastrous expedition of Major Thornburgh, and the surrounding tribes were said to be already in a ferment), we emerged from the mountains upon the great sea of black lava which seems to stretch illimitably westwards. With minds keenly excited by the incidents of the journey, we rode for hours by the side of that apparently boundless plain Here and there a trachytic spur projected from the hills, succeeded now and then by a valley up which the black flood of lava would stretch away into the high grounds It was as if the great plain had been filled with molten rock which had kept its level and wound in and out along the bays and promontories of the mountain-slopes as a sheet of water would have done. Copious springs and streams which issue from the mountains are soon lost under the arid basalt The Snake River itself, however, has cut out a deep gorge through the basalt down into the trachytic lavas underneath, but winds through the desert without watering it. The precipitous walls of the cañon show that the plain is covered by a succession of parallel sheets of basalt to a depth of several hundred feet. Here and there, I was told, streams that have crossed from the hills and have flowed underneath the lava-desert issue at the base of the cañon-walls, and swell the Snake River on its way to the Pacific The resemblance of the horizontal basalt-sheets of this region to those with which I was familiar at home brought again vividly before my mind the old problem of our Miocene dykes and Richthofen's rejected type of "massive" or fissure eruptions I looked round in vain for any central cone from which this great sea of basalt could have flowed. It assuredly had not come from the adjacent mountains, which consisted of older and very different lavas round the worn flanks of which the basalt had eddied. A few solitary cinder cones rose at wide intervals from the basalt plain, as piles of scoriæ sometimes do from the vapour vents on the surface of a Vesuvian lava-stream, and were as unequivocally of secondary origin. Riding hour after hour among these arid wastes, I became convinced that all volcanic phenomena are not to be explained by the ordinary conception of volcanoes, but that there is another and grander type of volcanic action, where, instead of issuing from separate vents and piling up cones of lava and ashes around them, the molten rock has risen in fissures, sometimes accompanied by the discharge of little or no fragmentary material, and has welled forth so as to flood the lower ground with successive horizontal sheets of basalt. Recent renewed examination of the basalt-plateaux and associated dykes in the west of Scotland has assured me that this view of their origin and connection, which first suggested itself to my mind on the lava-plains of Idaho, furnishes the true key to their history

The date of these lava-floods of the Snake River is in a geological sense quite recent. They have been poured over the bottoms of the present valleys, sealing up beneath their sheets of solid stone river-beds and lake-floors with their layers of gravel and silt. The surface of the lava is in many places black and bare as if it had cooled only a short while ago Yet there has been time for the excavation of the Snake River cañon to a depth of 700 feet through the basalt-floor of the plain. In so arid a climate, however, the denudation of this floor must be extremely slow Much of the plain is a verdureless waste of loose sand and dust which has gathered into shifting dunes. Save in the gorges laid open by the main river and some of its tributaries hardly any sections have yet been cut into the volcanic floor Dykes and other protrusions of basalt occur on the surrounding hills, but the chief fissures or vents of emission are still no doubt buried beneath the lava that escaped from them.

In North-Western Europe, however, the basalt-sheets were erupted as far back as Miocene times. Since then, exposed to many vicissitudes of geological history—subterranean movement and changes of climate, with the whole epigene army of destructive agencies, air, rain, frost, streams, glaciers, and ice-sheets—the volcanic plateaux, trenched by valleys two or three thousand feet deep and a mile or more in breadth, and stripped bodily off many a square mile of ground over which they once spread, have been so scarped and cleft that their very roots have been laid bare. Viewed in the light of the much younger basalts of the Western Territories of North America, their history becomes at last intelligible and more than ever interesting. We are no longer under the supposed necessity of finding volcanic cones vast enough to have poured forth such wide-spread floods of basalt. The sources of the molten rock are to be sought in those innumerable dykes which run across Britain from sea to sea, and which in this view of their relations at once fall into their place in the volcanic history of the time.

No more stupendous series of volcanic phenomena has yet been discovered in any part of the globe. We are first presented with the fact that the crust of the earth over an area which in the British Islands alone amounted to probably not less than 100,000 square miles, but which was only part of the far more extensive region that included the Faroe Islands and Iceland, was rent by innumerable fissures in a prevalent east and west or south-east and north-west direction. These fissures, whether due

to sudden shocks or slow disruption, were produced with such irresistible force as to preserve their linear character and parallelism through rocks of the most diverse nature, and even across old dislocations having a throw of many thousand feet. Yet so steadily and equably did the fissuring proceed over this enormous area, that comparatively seldom was there any vertical displacement of the sides. We rarely meet with a fissure which has been made a true fault with an upthrow and downthrow side.

The next feature is the rise of molten basalt up these thousands of fissures. The most voluminous streams of lava that have issued from any modern volcanic cone appear but as a minor manifestation of volcanic activity when compared with the filling of those countless rents over so wide a region. Mining operations in the Scottish coal-fields have shown that dykes do not always reach the surface. In all parts of the country, too, examples may be observed of breaks in the continuity of dykes. The same dyke vanishes for an interval and reappears on the same line, but is doubtless continuous underneath. What proportion of the dykes ever communicated with the surface at the time of their extravasation is a question that may perhaps never be answered. It is difficult to believe that a considerable number of them did not overflow above ground even far to the east of the main and existing outflows But so extensive has been the subsequent denudation that all trace of such superficial emission has been removed The general surface of the country has been lowered by sub-aerial waste several hundred feet at least, and the dykes now protrude as hard ribs of rock across the hills.

Traced westwards the dykes increase in abundance, till at last they reach the great basaltic plateaux Macculloch long ago sketched them in Skye, rising through the Jurassic rocks and merging into the overlying sheets of basalt. Similar sections occur in the other islands and in the north of Ireland The lofty mural escarpments presented by the basalt plateaux once extended far beyond the limits to which they have now been reduced. The platform from which they have been removed shows in its abundant dykes the fissures up which the successive discharges of lava rose to the surface, where they overflowed in wide level sheets like those still so fresh and little eroded in Western North America

That there were intervals between successive outpourings of basalt is indicated by the occasional interstratification of seams of coal and shale between the different flows. These partings contain a fragmentary record of the vegetation which grew on the neighbouring hills and which may even have sometimes found a foothold on the crumbling surface of the basalt floor until overwhelmed by fresh floods of lava. Not a trace of marine organisms has anywhere been found among these interstratifications There is every reason to believe that the volcanic eruptions were all subaërial. Sheet after sheet was poured forth over the wide valley between the mountains of Donegal and the Outer Hebrides on the one side and those of the north-east of Ireland and the west of Scotland on the other, until the original surface had been buried in some places 3000 feet beneath volcanic ejections.

I believe that the most stupendous outpourings of lava in geological history have been effected not by the familiar type of conical volcano, but by these less known fissure-eruptions Both types are of course only manifestations in different degrees of the same volcanic energy. It is by no means certain that the "massive" or fissure type belongs wholly to former geological periods. In particular one is disposed to inquire whether the great Icelandic lava-floods of 1783—the most voluminous on record—may not have been connected rather with the opening of wide-reaching fissures than with the emissions of a single volcanic cone The reality and importance of the grander phase of volcanism marked by fissure-eruptions have been recognised by some of the able geologists who in recent years have explored the Western States and Territories of the American Union But they have not yet received due acknowledgment on this side of the Atlantic, where the lesser type of cones and craters has been regarded as that by which all volcanic manifestations must be judged. We are fortunate in possessing in the north-west of Europe so magnificent an example of fissure-eruptions, and one which has been so dissected by denudation that its whole structure can be interpreted. The grand examples on the Pacific slope of America have yet to be worked out in detail, and will no doubt cast much fresh light on the subject, more especially upon those phenomena of which in Europe the traces have been removed by denudation But the other continents also are not without their illustrations. The basaltic plateaux of Abyssinia and the "Deccan traps" of India probably mark the sites of some of the great fissure-eruptions which have produced the lava-fields of the Old World. In their recent admirable *résumé* of the "Geology of India," Messrs Medlicott and Blanford describe the persistent horizontality of the vast basalt-sheets of the Deccan, the absence of any associated volcanic cones or the least trace of them in that region, and the abundance of dykes in the underlying platform of older rocks where it emerges from beneath the volcanic plateaux. They confess the difficulty of explaining the origin of such enormous outpourings of basalt by reference to any modern volcanic phenomena Their descriptions of these Indian Cretaceous lava-floods might, however, be almost literally applied to the Miocene plateaux of North-western Europe and to the Pliocene or recent examples of Western North America. ARCH GEIKIE

THE ATOMIC THEORY

The Atomic Theory. By Ad. Wurtz, Membre de l'Institut, &c. Translated by E. Cleminshaw, M.A (London C. Kegan Paul and Co., 1880.)

THE latest addition to the International Scientific Series is at once a scientific treatise and an artistic work. The translator has very fairly maintained the clearness and crispness of the French style, whereby the book is marked with a distinct individuality and self-completeness.

The sharpness of the impression which this work produces on the mind is gained without making any great sacrifice of accuracy, although it must be confessed there is, in some chapters, a lack of detailed facts, which is against the value of the work as a reference book for the advanced student; and in others there is too free a use of fancy, which faculty is not synonymous with that

other without which no great scientific work can be produced, viz., imagination.

The work is divided into two books. the first, and most valuable, treating of "Atoms," the second of "Atomicity." The historical introduction is very full, and remarkable for the clear exposition of the work of Richter, which was of so much importance in the subsequent development of the doctrine of atoms. The error, which is still fallen into in some books, of attributing the "law of proportionality" to Wenzel is pointed out and corrected.

Full justice is not done to the work of Avogadro, on which, confirmed as it has been by physical evidence, rests the structure of modern chemistry. The distinction between "integral molecules" and "elementary molecules" was clearly stated by Avogadro in 1811, three years before the date of the publication of Ampère's letter to the Comte Berthollet. Ampère's attempt to extend the hypothesis to facts concerning crystalline bodies cannot be regarded as an improvement on the simpler conception of Avogadro.

But throughout this work there is a manifest resolve to abate no jot nor tittle of that assertion, which, made with the plenary knowledge of a chemical Philistine, sounded the keynote of M. Wurtz's well-known "History of the Atomic Theory."

The statement on p 42 of the reasons for adopting H_2 as the standard of molecular weights is neither clear nor satisfactory The student might readily suppose that this standard is adopted simply for the sake of convenience; he might also be led to regard the statement of Avogadro's law, on this page, as a deduction from some vaguely-expressed relations between the number of atoms in elementary molecules and the volumes occupied by these atoms

Few text-books make clear the fundamental deficiency of the Daltonian theory, viz, the absence of any trustworthy means for determining the weights of the "atoms" (or as we now say, molecules) of compound bodies Dalton, and Berzelius after him, laid down rules for determining these weights, but the rules of both chemists were wholly empirical. "The atomic weight of an element is the smallest amount of that element which combines with unit-weight of hydrogen to form an atom of a compound," but so long as the "atom" of the compound was undefined, the atomic weight of the element could not be determined.

Avogadro furnished chemists with a means of determining the molecular weights of all gasifiable bodies, and in modern chemistry determinations of molecular weights of many compounds of a given element, and analyses of these compounds, must precede the determination of the atomic weight of the element itself

The atomic weight of an element is the smallest amount of that element—referred to hydrogen as unity—contained in the molecule, that is in two gaseous volumes of any compound thereof For lack of a clear differentiation between atom and molecule, and for lack of a definite statement of how atomic weights are determined, the full and valuable table, extending from p. 104 to 109, loses much of its meaning This table, by the way, very closely resembles a table which occurs in Lothar Meyer's "Die modernen Theorieen"; the alterations made by M. Wurtz certainly do not add to the value of the table.

Dalton's objections to the generalisation of Gay Lussac, that "equal volumes of gases contain equal numbers of atoms," was, as we now know, perfectly justifiable, but on p. 35 Dalton is said to have repudiated "the solid support which the great French chemist gave to his ideas."

Gay Lussac's generalisations could not be true, said Dalton, because of such a reaction as that between nitrogen and oxygen, wherein equal volumes of each combine, and the product, nitric oxide, measures twice the volume of either; that is, there are, according to Gay Lussac, twice as many atoms of nitric oxide as of oxygen or nitrogen, but as elementary atoms are chemically indivisible, this is impossible. Berzelius obviated, or rather shirked, the difficulty by applying Gay Lussac's generalisations to elementary gases only, but a full reconciliation between the views of Dalton and those of Gay Lussac was only possible when Avogadro's fruitful idea of the existence of molecules as distinct from atoms was fully recognised in chemical science.

In describing the physical methods for checking atomic weight determinations, the law of Dulong and Petit is stated in too absolute a manner, if the data concerning the specific heats of the elements are carefully considered, it is evident that in many cases the value varies very much with temperature, that in others no direct determination of specific heat has yet been made, and that the law cannot be regarded as a final statement of the connection between the specific heats and atomic weights of the elements

The state of our knowledge with regard to the structure of molecules, indeed, renders a full understanding of specific heat at present impossible. The dynamical theory of gases has not yet been fully worked out in this direction.

Although the "law of Avogadro" is a deduction from the dynamical theory of gases, and as such is invested with an authority which no mere collection of empirical facts can bestow upon it, yet nowhere in M. Wurtz's book is this insisted upon.

The compromise between an atomic and an equivalent system of notation, which was so long adopted by chemists, is well described and its evils fully laid bare.

The objectors to Avogadro's law are more numerous and more important in France than in this country or in Germany, hence M. Wurtz devotes considerable space to the subject of dissociation, which he discusses with much clearness and wealth of illustration.

The demonstration on pp. 121-123 of the monatomic character of the mercury molecule is admirable.

In the list of names of those who have pointed out relations between the atomic weights of elements and properties of their compounds, there is a serious omission, viz, the name of A. R. Newlands. This subject of relation between atomic weights and properties of compounds is discussed on pp. 154-176. A better idea of Mendelejeff's "periodic law" may be obtained from these pages than probably from any other English text-book, but surely it would have been well had the author more explicitly acknowledged his indebtedness to Lothar Meyer's work. The graphic representation of the relations between the atomic weights and physical properties of the elements—taken from Meyer's book—has not hitherto been in the hands of the English student.

The second part of M. Wurtz's book, dealing with Valency, is not, in our opinion, of equal value with the first.

After reading these chapters one finds it hard to find a reason for introducing into science the conception of valency, so variable and shifting is this property of atoms made to appear.

On p. 229 it is stated that chlorine is monovalent in $HClO$, pentavalent in $HClO_3$, and heptavalent in $HClO_4$.

Scarcely a hint is given of the many objections to extending considerations concerning valency, in any but a most tentative manner, to non-gasifiable bodies. The theory of molecular as distinct from atomic compounds is dismissed; all are regarded as atomic, and the valencies of the atoms seem variable at pleasure. Where proof of the valency of atoms is not forthcoming, assertion is used in its place

The author's treatment of affinity is not satisfactory "Affinity is the force of combination, chemical energy." "Atoms attract each other, and this atomic attraction is affinity." "Thus we know that while hydrogen is united to chlorine with extreme energy, oxygen combines with less force" Surely the translator is to blame for some of these sentences.

The theory of valency deserved a more rigorous and exact treatment than M. Wurtz has given it.

We leave the book, feeling that it is the production of a brilliant author, not the work of a deep thinker

NEW ZEALAND MOLLUSCS

Manual of the New Zealand Mollusca By Frederick Wollaston Hutton, F.G.S. Published by command. (Wellington, 1880)

IN an interesting article which appeared in NATURE, vol. xxii. p. 461, entitled "The New Zealand Institute," attention was called to the publications of the Institute and to the excellent work in science achieved by the author of the manual above mentioned, and by many other naturalists, as well by geologists, chemists, astronomers, archæologists, physicists, and philosophers. When the traditional New Zealander visits the ruins of the old country, it is to be feared that he will lament our ignorance instead of expressing his admiration of our past eminence.

Prof. Hutton seems to have contributed to the publications of the Institute a number of valuable papers on "the various divisions of the fauna of New Zealand" We are not quite sure that our knowledge of any one department of the fauna would be so much advanced by a multifarious zoologist as by a specialist who has devoted himself to the study of that department. The division of labour is not less desirable in natural history than in other equally extensive fields of work. The material is so vast that a Linné, Buffon, or Cuvier would be now rather an anachronism than a marvel.

The present work is called "A Systematic and Descriptive Catalogue of the Marine and Land Shells, and of the soft Mollusks and Polyzoa of New Zealand and the adjacent Islands." It belongs to the Colonial Museum and Geological Survey Department, of which Dr. Hector, the well-known geologist, is the director. Its scope is most useful; and, as the preface by Dr. Hector very properly states, "an accurate knowledge of the affinities and distribution of the recent shells of New Zealand is a very necessary element in the geological survey of the country, as it must form the basis of our Tertiary geology, upon the correct deciphering of which many questions of the highest interest depend" And he adds, "Shells afford the most reliable data for palæontologists, but before the extinct shell-fauna can be utilised, the recent shells of the area must be thoroughly determined." This is quite true. We are disposed, however, to carry the process a step further. It is not enough to determine or make out the recent shells, but they must be critically compared with their fossil analogues. For want of such comparison the late Prof Nyst, M Vandenbroeck, and other Belgian palæontologists have unfortunately caused some confusion by a wrong identification of recent or living species with Tertiary species.

The "Manual" contains 237 pages. There are no plates or illustrations. It appears to comprise all that is known of the subject, and to have been conscientiously and on the whole carefully written But, like all other books, it is not faultless In the Bibliography "Linneus" is the name given as the author of the 12th edition of the "Systema Naturæ" It ought to be "Linné," according to the title-page and dedication "Gastropoda" is now the usual, as well as correct, spelling of the class, not "Gasteropoda" The shell of the family *Patellidæ* is not a simple cone, but is spiral in the young The *Bullidæ* are not all eyeless The sub-order "Lucinacea" is described as having the gills, "one on each side", but in one of the families of this sub-order there are "two gills on each side" The family "*Radulidæ*" is stated to have the foot "not byssiferous"; *Limahians* with its foot spins a byssus and makes its curious nest. In the "Artificial Key to the Marine Shells" the remarkable class *Solenoconchia* (or as Prof. Hutton in another place prefers to call it, "Scaphopoda") is omitted The shell in "*Capulidæ*" is described as "not spiral" These and other less important errors can be corrected in a future edition. We regret, but are not surprised, to see the remark that "not much dependence can be placed on the localities in Mr. Cuming's collection," which was purchased for the British Museum at a large price. This is the case with all dealers, and it sadly disturbs our ideas of geographical distribution We are inclined to question even such species as *Ostrea edulis*, *Mytilus edulis* and *Lucina* (*Loripes*) *divaricata* as indigenous to New Zealand. These are included in a list of sixty-four species believed by the author to be the only New Zealand species of which there is evidence that they are found anywhere else, although he admits that the identification has in most cases been made solely by descriptions and figures. The same remark applies to *Cypræa europæa*, "*Philippia lutea*" = *Solarium hybridum*, *Littorina cærulescens* = *neritoïdes*, and *Crepidula unguiformis*. But, *per contra*, the *Saxicava australis* of Lamarck is scarcely a variety of *S rugosa*, Linné. The diagnosis of the soft parts, or "animal," of *Vitrina* and *Succinea*, viz, "too large to enter the shell," does not suit the European species of those genera. In the family *Assimineidæ* the eyes are placed not "on the middle of the tentacles," but on their tips. "*Odostomia lactea*" is not the Linnean species of

Turbo, but another species so named by Mr. Angas Nor is the *Nucula sulcata* of A. Adams the same as Bronn's much older species of that name. But a serious defect of the work consists in the description of the shells. We give one instance among many. *Littorina novæ zealandiæ* is described as "somewhat globosely turbinated," with the whorls "spirally irregularly linearly grooved;" and the characters of the several species are not arranged systematically or in any kind of sequence. Dog-Latin would be almost preferable to such English. Perhaps, however, the description of species made by the late Mr Reeve may have been copied from his "Conchologia Iconica" Prof. Hutton says that there are "between 300 and 400 species" of the New Zealand mollusca and polyzoa This is considerably less than half the number of those species which have been recorded as inhabiting the British seas. J. GWYN JEFFREYS

OUR BOOK SHELF

The Zoological Record for 1878, being vol xv of the Record of Zoological Literature, edited by E. C. Rye. (London · John Van Voorst, 1880)

THIS publication seems to pursue the even tenor of its very useful way. The editor has to acknowledge grants of 250*l* towards the expenses of the work from the British Association for the Advancement of Science, the Royal Society, and the Zoological Society of London. The "Record of the Arachnida for 1878" has been unavoidably postponed until vol xvi, and Mr. Kirby has for the future undertaken all of the groups of the Insecta with the exception of the Coleoptera, which the editor will still review. Entomologists will perceive with regret that they thus lose the services of Mr McLachlan, who has reported on the Neuroptera and Orthoptera since 1869 A special committee has been appointed to endeavour to expedite the publication of the annual volume, and arrangements have been made, both as regards the contributors and printers, which it is hoped will have the eventual effect of bringing out the record of one year's work during the succeeding year This would be an immense boon, and though it is obvious that it cannot be effected at the first attempt, still the editor confidently expects that the Record of 1879 will be published in the beginning of 1881, and let us hope that ere the end of that year we may also have the Record of that one now coming to a close.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts No notice is taken of anonymous communications*]

[*The Editor urgently requests correspondents to keep their letters as short as possible The pressure on his space is so great that it is impossible otherwise to ensure the appearance even of communications containing interesting and novel facts.*]

The Recent Gas Explosion

ON my return after the vacation the experiments on the explosion of gases in tubes were continued.

A tube was constructed by winding narrow strips of paper helically round a glass tube about 8 mm. in diameter, two-thirds of the width of the paper being glued, it was so wound as to make a tube of three thicknesses of paper. The interior of the tube was afterwards varnished with shellac At the ends short pieces of glass tube about 5 mm. in diameter were fixed, one being provided with platinum wires in order to inflame the gas; the total length of the tube was 4360 mm.

The tube was filled with a mixture of oxygen and hydrogen, the end of the glass tube with the wires was plugged with wet cotton wool, the other tube being closed with an india rubber cap; a spark was then passed. At a distance of 650 mm. from the open end, at which the ignition took place, the outer covering of the tube was split; at a distance of 1,900 mm. from the same point was a hole, at 3030–3040 another hole, and at 3085–3100 a third hole The india-rubber cap was blown off the end of the tube. At the third hole the interior coating of the tube was torn and blown back towards the opening, showing that the orifice had allowed the escape of gas from both directions. Measuring the distances between the holes and the ends of the tube, we have the following numbers:—From end to first split, 650 mm.; from split to first hole, 1250; from first hole to mean of second and third, 1200; from this point to end of tube, 1260

There seemed to be some doubt as to the uniformity of this tube, so another was made by rolling a strip of paper helically along a glass tube in such a manner that the edges did not overlap. A glued strip was wound over this so as to cover the joint; and a third to cover the joint of the second, the edges not overlapping and yet touching one another throughout. The process was very tedious, and as the result showed, not successful. This tube was 7 5 mm. in diameter, and the glass ends 4·5, the total length being 8390 mm. The end of the tube farthest from the wires was firmly closed, after introducing the explosive mixture When the gas was exploded in the tube 14 holes were made, in some places the tube giving way at joints, but without any great tear of the paper Starting from the end of the tube the first hole was at 620 mm., the other holes being distant from one another 650, 530, 100, 475, 375, 320, 580, 455, 370, 885, 2115, 365, 85, and the other end 465 from the last hole

A third tube was now constructed, but on a different principle A sheet of glued paper was wound round a brass tube and at once removed, in this way a tube about 275 mm long and 13 5 wide, and consisting of about 5 layers of paper was obtained. Thirty-two of these were joined end to end by glueing narrow strips of paper round the joints The tube was varnished inside and out, and when completed was 9000 mm. long. The experiment was made after dark, and it was not found out until afterwards that a small quantity of water had entered the tube from the gas holder while introducing the gas In this case the explosion made 10 holes, but the joints obviously considerably strengthened the tube in their neighbourhood The distances between the holes were not more regular than in the previous case. From the end to first hole 757 mm; the other holes being distant 660, 1595, 146, 484, 230, 295, 308, 1325, 585, to end 2615 The end was not opened by the explosion.

Although these experiments have not exhibited the regularity I anticipated, they show that a tube burst by an explosive mixture must not be expected to open along its whole length.

Cooper's Hill, October 25 HERBERT MCLEOD

Geological Climates

I WAS not surprised at reading Mr. Duncan's letter in supposed reply to my communication to NATURE, vol. xxii p 532, as it fully proves my case against the slipshod logic of geologists in general He writes:—"Where I now write, on the Bagshot sands and gravels of Cooper's Hill, facing the cold north with a touch of the east, there is a patch of bamboo canes in full leaf. They were in full leaf at this time last year The plant survived out of doors the extreme frost and fogs of last winter and other evidences of a temperate climate, and it has been in beautiful leaf all this summer.

"Now everybody knows that in torrid India the bamboo grows. . . ."

Mr Duncan might as well have told your readers that where he now writes, "facing the warm south with a touch of the west," he beheld before his astonished eyes a tuft of grasses.

He has not named the *species* of the "patch of bamboo canes" which delighted his eyes, and which "everybody" knows came from "torrid India"

If Mr. Duncan does not know, at least "everybody" does, that species of the bamboo canes flourish in every latitude from Northern China to Southern Chili, including "torrid India," where in some places you may have a half-inch thick of ice, in consequence of the starlight radiation of a clear summer's night.

I have before me a list of twenty-four species of bamboo canes cultivated in most of the gardens of Europe, but they are all, with the exception of a species from the Himalayas (not "torrid India"), imported from the severe climates of Northern Japan and China.

At Fota, in the Cove of Cork, at Bamboo Island, they have lived, fruited, and reproduced themselves for nearly thirty years, and will probably continue to do so in the future, although no Corcagian will be silly enough to believe in consequence thereof that he is living in the climate of "torrid India."

In fact, I adduced the evidence of *Araucaria Cunninghami*, *a most delicate self-registering plant thermometer*, in testimony of the Eocene climate of Bournemouth; and I find myself confronted with Mr. Duncan's clumsy thermometer with *not a single fixed point on its scale*, in the shape of an unspecified "*clump of bamboo canes*." Let Mr. Duncan name the species included in his "clump," and I shall discuss the question fully with him.

The facts stated in my letter, although by no means uncommon, prove most convincingly to those who can appreciate them the untenable nature of Lyell's theory of the cause of change of geological climates.

I must state my argument again :—

1. In Eocene times groves of Moreton Bay pine lived, flourished, and held their ground at Bournemouth against all comers

2. At the present time groves or forests of Moreton Bay pine live, flourish, and hold their ground at Moreton Bay against all comers.

3. Therefore the climate of Bournemouth in Eocene times was similar to that of Moreton Bay at the present time.

Geologists often make use of syllogisms much less conclusive than the above, which is as good as any commonly used in biological reasoning, such as it is.

The present mean temperature of Bournemouth is 20° F. below what it was in Eocene times, which is equivalent to a difference of latitude in the northern hemisphere between 31° N. and 51° N.

Sir Charles Lyell[1] feebly attempts to get rid of scientific conclusions as to temperature in two ways :—

1. By a denial of the specific identity of the former and recent species compared.

2. By the unproved hypothesis of competing plants whose superior vigour and not climatal conditions, account for the absence of the species which formerly flourished

In the case of the Moreton Bay pine I shall leave Mr. Gardner to defend the asserted identity of species, and I meet Sir Charles Lyell's second supposition (which is really romance writing, and not science) by the assertion that the Moreton Bay pine, even if protected by man, will perish in any locality whose *mean winter temperature* falls below 57° F.

The present mean January temperature of Bournemouth is 37°·4 F., a temperature which would destroy in a single night a whole forest of Moreton Bay pines.

I was of course well aware that my argument from the former existence of Moreton Bay pines at Bournemouth was only one of many similar arguments that might be advanced from the former existence of plants or corals in localities in which they do not now live.

I know nothing, except from books, of the water temperature necessary for the several species of corals, nor do I know whether any species of the tertiary corals found in England are *specifically identical* with corals now living elsewhere. If Mr Duncan would give us precise information on this subject he would throw most valuable light on geological climates.

The corals would give us more information upon the question than plants, because they would gauge for us the temperature of the water in England, that is to say, the temperature of the former Gulf streams of the tertiary period, from which we could calculate numerically the increase of solar radiation, necessary to produce such former Gulf streams, and possibly afterwards a measure of geological time.

I have elsewhere[2] shown that the fossil tertiary plant beds of the Arctic regions show a falling off of temperature similar to that which has been proved at Bournemouth, of which the following is a summary :—

	Lat.	Mean annual temperature in Miocene time.	Reduction at present
	°	°	°
Grinnell Land	81 44	42·3 F.	44·00 F.
Spitzbergen	78 00	51·8 ,,	33·30 ,,
Disco	70 00	55·6 ,,	36·00 ,,
		Eocene	
Bournemouth	50·50	70·75 ,,	20·35 ,,

I again assert that it is not possible to explain these facts without introducing causes differing in amount from those now acting on our planet SAML. HAUGHTON

The Yang-tse, the Yellow River, and the Pei-ho

I READ with great interest the paper on the Yang-tse, &c, in NATURE, vol xxii p. 486. It seems to me that Mr Guppy has underestimated the quantity of water and sediment in these rivers As to the Yang-tse, this arises from the year 1877 being one of the driest in Western and Central China generally, and thus the summer flood must have been one of the lowest on record. Besides what we know of the character of the season, an indirect proof of this can be had by comparing the rate of discharge in April and at the time of highest flood, as given by Mr. Guppy, with what is said by Mr. Oxenham, in his paper on the inundations of the Yang-tse.[1] According to the latter the rise of water in April is not very large, the river not yet inundating its banks, and being thirty feet below the summer level. Thus in an average year the discharge in April would by far not equal half of that of August, as found by Mr. Guppy, but more probably be even below one-fifth of that of flood time

On this account the data given by Mr. Guppy for the Yang-tse are far below the average as to the discharge of water, and probably even more so as to the amount of sediment, as the proportion of sediment increases during high floods. In 1877 the loess country of North-West China was subject to the severest drought, so that the Han river, which generally contributes so much to the sediment of the main river, must have been very low in summer.

As to the estimation of the discharge of water in the Pei ho, it is certainly much below the actual quantity, for Mr. Guppy has taken only the months of December to March, *i.e.* months of low water. The monsoon character of the rains, *i.e.* the great prevalence of summer over winter rains, is far more marked in Northern China than in the middle part of that country, so that the flood discharge of the rivers during and after the rains (*i.e.*, from July to October) must be enormously in excess over that of winter. If, as Mr Guppy says, the Pei-ho rises only six feet at Tien-tsin, this must be due to the banks being very low, so that the river during flood-time inundates the plain to a very great extent.

My conclusion is this.—Mr. Guppy having underestimated the discharge of water of the Yang-tse and Pei-ho in the mean of the year, this must have been even more the case as to the amount of sediment carried. Thus the relatively short time at which he estimates that the surrounding seas will be filled by the sediment carried by the great Chinese rivers has to be greatly shortened, and if he thinks 36,000 years enough for the work, I should estimate that 28,000 years would be sufficient.

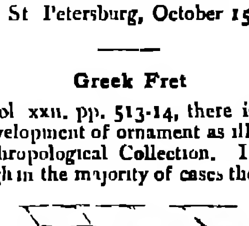
Greek Fret

IN NATURE, vol xxii. pp. 513-14, there is a very interesting account of the development of ornament as illustrated by General Pitt Rivers' Anthropological Collection. I would venture to suggest that though in the majority of cases the Greek fret pattern



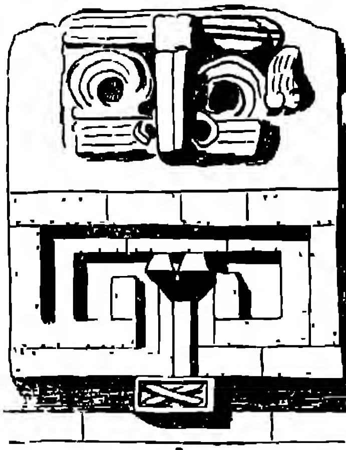
1

FIG 1.—Gateway at Labnah (Plate 19).

was independently evolved in different countries from the "double loop-coil," yet a study of the plates in Mr Catherwood's beautiful work, "Views of Ancient Monuments in Central America" (1844), suggests to me the probability that the builders of those remarkable structures arrived at the "Greek pattern" through a degradation of the conventionalised human

face. The accompanying tracings from Catherwood's work will sufficiently explain my meaning.

Fig. 1, from the gateway at Labnah, pl. xix.; Fig. 2, from the gateway of the great Teocallis Uxmal, pl. xii., Fig. 3, from

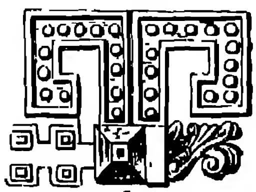


2

Fig. 2.—Gateway of the Great Teocallis Uxmal (Plate 12).

Las Monjas Chichen Itza, pl. xxi., illustrate the development of the fret. Fig. 4, from Las Monjas Chichen Itza, pl. xxi, shows another modification of the human face.

In his "Grammar of Ornament" Owen Jones says (p 35) "In Mr. Catherwood's illustrations of the architecture of Yucatan



3

Fig. 3.—Las Monjas Chichen Itza (Plate 21)

we have several varieties of the Greek fret: one especially is thoroughly Greek. But they are, in general, fragmentary like the Chinese." The reason I would assign for this "fragmentary" nature of the design is that it was just passing from the disjointed *ornament* to the *pattern* stage. An examination of the plates

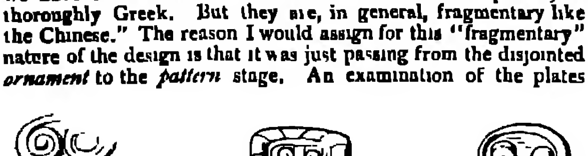


Fig. 4.—Las Monjas Chichen Itza (Plate 21)

will prove the profuse employment of the more or less grotesquely modified human face in mural decoration.

The hypertrophy of one set of organs, with the atrophy of another, and modification of a third, are paralleled in the specialisations of all degraded forms. ALFRED C. HADDON

Zoological Museum, Cambridge

Temperature of the Breath

I AM unable to see what bearing "I. J. M. P.'s" suggestion that I should try the effect of dipping my thermometer, enveloped in a tightly rolled handkerchief, in water at 108° has on this subject. Every one of course knows that a thermometer in such circumstances would eventually acquire the temperature of the water in which it is immersed.

The state of the matter is simply this. On the one hand works on physiology agree in stating that the normal temperature of the breath is from 95° to 97°, and that of the interior of the body from 98°·5 to 99°·5. These are what Mr. McNally would call "ascertained physiological truths." On the other hand I find that by breathing on the bulb of a thermometer enveloped in about twenty folds—more or less—of a silk, cotton, or woollen cloth for five minutes, the thermometer indicates temperatures varying—owing to conditions not yet precisely ascertained—from 102° to 108°, which, as every one knows, are temperatures vastly greater than the accepted temperature of the breath or interior of the body.

There is no question of squeezing up the reading of a delicate thermometer by the tightness of the enveloping material, for the thermometer used in these experiments is an ordinary clinical thermometer, such as I use daily in practice, the bulb of which is made of such stout glass that no amount of pressure short of breaking the bulb will move the mercury in the slightest degree.

The following variation in the mode of experimenting precludes the possibility of any pressure on the thermometer. I put the thermometer in a glass tube about three-fourths of an inch bore, open at both ends, packed the stem loosely with cotton wool, but left the bulb free at one end of the tube. I then enveloped the whole in a silk handkerchief and breathed through twelve folds of the material into the end of the tube where the bulb of the thermometer was, untouched by cotton wool, glass tube, or silk handkerchief. After five minutes the thermometer showed a temperature of 102°. In this case, and I believe also in my former experiments, the enveloping material merely acted as a bad conductor, retaining the heat produced by the breath.

As any one can easily repeat these experiments for himself, I would suggest to your correspondents that they should do so. When the facts have been established by reiterated experiments —my own observations have been corroborated by several of my friends—the explanation or significance of them will no doubt be speedily arrived at. Provisionally I suggest that these observations show respiration to be a powerful agent for getting rid of the superfluous caloric of the body.

How is this heat communicated to the breath? If it had anything to do with the conversion of the carbon of the blood into carbonic acid, the quantity of carbonic acid passed off by the breath would be greater when the temperature of the latter is higher, less when it is lower. But Letellier's experiments show that the amount of carbonic acid exhaled is greatly *increased by external cold*, and *diminished by heat*, whereas my experiments apparently show that the temperature of the breath is *lower in external cold, higher in heat.*

To solve the questions suggested by these experiments one would require the aid of a physiological laboratory, but as that is not at my command, and, moreover, as I could not devote the necessary time to them, I must leave their solution to others.

October 20 R. E. DUDGEON

Soaring of Birds

I BEG to send you some data on the above subject, as I live where the phenomenon is of daily occurrence. Most of the large birds out here soar, *i.e.* can circle round and round without flapping the wings, and also can *rise* thus from 100 or 200 feet to some 8,000 by same means. The pelican, the adjutant, and several large birds allied to it, the vulture and the cyrus, rise thus.

Firstly they rise by flapping the wings vigorously, and when up some 100 or 200 feet, *if there is a breeze*, begin to soar in large circular sweeps, rising 10 to 20 feet at each lap, the whole bird being otherwise quite motionless, and the wings extended rigidly.

We have two steady winds here, from north east and west-south-west, and in one of these the birds rise to great heights, and can be seen as small specks up in the blue, and watched with telescope, going round and round, motionless otherwise. The following data are trustworthy —The birds weigh from 20 to 40 lbs.; spread of wings, 10 to 12 feet, stand 3 to 5 feet high, speed flying or soaring, about 15 to 35 miles per hour (estimated).

They rise by flapping the wings. If there is no wind they $\left\{\begin{array}{l}\text{do not}\\\text{cannot}\end{array}\right\}$ soar; they generally begin to soar at 100 to 200 feet elevation when above the level of the forest. In soaring they $\left\{\begin{array}{l}\text{do not}\\\text{cannot}\end{array}\right\}$ go in a right line, but in large curves of a spiral that leans to *leeward.*

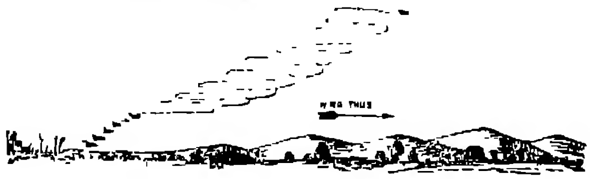
At each lap they can rise 10 to 20 feet, but lose position laterally of 20 to 50 feet to leeward. The soaring can go on without once flapping the wings, till the bird is almost out of sight.

If near, the feather-tips make a loud musical "sing," and the presence often first known by it. If watched, they come

round again nearly to the same place. With gun or rifle against a tree-stem, I have often been able to spot the intersection with my aim beforehand, lap by lap; the drift is to leeward.

I take it the explanation is, that in passing round *with* the wind, and by slightly falling, great impetus is gained, which is slowed down by turning to meet and rise on the wind *like a kite* (if near, this is *seen*). I have seen the albatross and gulls floating, but this case or these cases exemplify a major problem of rising as well steadily and without effort; it is also a clearer problem, the solution of which more or less solves the minor problems of mere flotation.

The line of flight is thus:—



Sapakati, Sibsagor, Asam S. E. PEAL

Regelation

IT is stated in NATURE, vol xxii. p. 589, that Faraday gave the name of *Regelation* to the phenomenon of two pieces of ice freezing together. Surely this is an error? It was in 1856 when Sir Joseph D. (then Dr.) Hooker, Professors Tyndall and Huxley, and the present writer were in Switzerland together. Prof Tyndall asked us to suggest a suitable term for the process, and it was Sir Joseph Hooker who said he could think of none better than *Regelation* Prof Tyndall instantly accepted it as exactly conveying the meaning he required.

Agassiz, however, in writing upon the difficulties of ascertaining the temperatures of glaciers by introducing thermometers into borings, alludes amongst others to "la difficulté d'extraire les fragmens détachés qui se *regelaient* constamment" ("Études sur les Glaciers," p. 203). This shows that a similar expression had occurred to him as suitable for this phenomenon, as early as 1840, in which year his "Études" were published

GEORGE HENSLOW

JOHANNES RUDOLF VON WAGNER

WE have already briefly alluded to the loss suffered by chemistry in the sudden death from heart-disease of Prof von Wagner, which occurred at Wurzburg, October 4 Johannes Rudolf Wagner was born February 13, 1822, at Leipzig As a student in the university of his native city he made choice of chemistry as a profession, and supplemented the then somewhat limited advantages of the Leipzig laboratory by a course of study at Paris, whither students from numerous countries were attracted by the brilliant lectures and investigations of Dumas. His residence there was followed by a lengthy journey to the various centres of scientific interest in France, Belgium, Holland, and Germany, after which he returned in 1846 to Leipzig to accept a position as assistant in the chemical laboratory of the university. In 1851 he was appointed Extraordinary Professor of Technical Chemistry at the Nurnberg Polytechnic. In 1856 he accepted a call to the Chair of Technology at the University of Wurzburg, a position which he occupied until the time of his death. During this same time he also filled two important offices, that of Director of the Technological Conservatory at Wurzburg, and (until 1868) that of Royal Examiner of the establishments for Technical Instruction in Bavaria. His peculiar abilities and wide range of experience led to his being frequently sent abroad by the Bavarian Government on scientific missions, notably in 1858 to England and Holland, and in 1861 to Paris. The same reasons led to his being called upon to play an important *rôle* in the International Exhibitions of the past twenty years. He was successively appointed on the juries for chemical products at the Exhibitions of London (1862), Paris (1867), and Amsterdam (1869). At Vienna (1873) he was the Chief Commissioner of Bavaria, and at Philadelphia (1876) he was a leading member of the German Commission The marked services which he rendered in connection with the Vienna Exhibition were recognised by his sovereign, who raised him to the nobility, and decorated him with the Order of the Crown. Prof von Wagner was the recipient likewise of numerous decorations from most of the European countries

The career of Wagner has been one of unusual and varied activity. Apart from the multifarious duties of an executive character which we have briefly enumerated, he found time to render to pure chemistry, and especially to applied chemistry, services of incalculable value. Like Poggendorff in physics and Kopp in pure chemistry, his inclination led him towards the literary side of his favourite studies, and it is on his accomplishments as an author that his fame chiefly rests. Still, as an investigator Wagner possessed remarkable and many-sided aptitudes, and his name is associated with numerous researches, the majority of which aim at the practical application of scientific facts, or seek to ascertain the chemical nature of important industrial products One of his first investigations (1847) was on yeast, and included a thorough study of its nature and growth, and especially of the influence exercised by the presence of foreign bodies on the phenomena of fermentation In 1849 he commenced a research on the oil of rue, which was carried on at various intervals, and to which we owe much of our knowledge of the constituents of this important essence. In 1850 he assigned to the alkaloid conine the structure of a dibutyryl-amine, a formula verified long after by Schiff's synthesis (1871) of paraconine, and by Michael and Gundelach's brilliant synthesis a few months since, of methyl conine. Among other noteworthy theoretical results, mention may be made of his extensive monograph on polymeric isomorphism (1851), and his experiments in the same year establishing the nature of mercur-ammonium compounds as substituted ammonias—mercury replacing hydrogen—by a distillation of the well-known "white precipitate" with amyl-mercaptan, which yielded sulphide of mercury and hydrochloride of amylamine. Shortly after he showed that the compounds imperatorin and peucedonine obtained from the roots of sulphur-wort and allied plants were identical, and established their chemical nature as angelate of the hydrate of peucedyle. One of Wagner's most important researches, commenced in 1850 and taken up several times since, had for an object the colouring-matters of fustic. In its course he discovered morin-tannic acid, which in company with morin gives to fustic wood its tinctorial properties. He studied carefully its reactions and its derivatives, and among the latter discovered pyrocatechin, the product of the destructive distillation of the acid In 1853 he undertook a thorough examination of the oil of hops, separating the different chemical components, and finding amongst them quercitrin and morin-tannic acid At this epoch he succeeded in obtaining the remarkable alloy formed by the union of four parts of potassium with 2½ parts of sodium, which is liquid at ordinary temperatures, and resembles mercury in appearance. In 1867 he contributed an interesting research on the rapid increase of solubility of carbonates in water containing carbonic acid under various pressures. At the same time he broached a theory of the formation of deposits of a graphite, in which he attributed it to a decomposition of cyanides in nature analagous to that occurring in the manufacture of soda Among his more important analytical researches were the determinations (1860) of the quantities of oil present in the nuts and seeds of many forest trees. As an able deviser of analytical methods Wagner exhibited numerous proofs. Among these mention may be made of the use of the iodine reaction for analysing chlorides of lime (1859), the use of iodine likewise for the determination of the alkaloids (1861), the volumetric deter-

mination of tannic acid by means of sulphate of cinchonine (1866), the test for wool in silk fabrics by using nitro-prusside of sodium to show the presence of the sulphur contained in wool (1867), the application of ammonium vanadate to detect the presence of tannin in red wines (1877), and other tests for detecting methyl-eosine in the presence of eosine, nitrobenzene in the oil of bitter almonds, paraffine in bees-wax, stearic acid in paraffine, &c. Equally numerous were the improved methods of preparing chemical compounds and products introduced by him, including the preparation of pelargonate of ethyl, used extensively in perfumery, of finely-divided copper, of rufigallic acid, of calcium iodide, of precipitated alumina, of chloride of mercury, of arsenate of sodium, of benzoic acid, &c.

Among Wagner's purely technical researches reference may be made to the application of pyrocatechin for photographic purposes (1855), the determination of densities for technical use (1859), the method for purifying water for tinctorial purposes (1863), the use of paraffine for preserving sodium, and his important research (1877) on the reactions of vanadium compounds with a large variety of organic commercial products, in the course of which he obtained several important tinctorial results.

As an author Prof. von Wagner has manifested a degree of talent and a fertility surpassed by but few of his scientific contemporaries. An easy, lucid style, an intimate familiarity with the entire range of subjects touched upon, a fulness of detail united to a logical, systematic treatment of the matters in question, and a happy adaptation to the wants of even elementary knowledge, have rendered his works universal favourites. This is especially true of his "Handbook of Chemical Technology," which has survived a twelfth edition in Germany, and has been rendered accessible to French and English-speaking students by the masterly translations of Gautier and Crookes. It is doubtful whether in any other branch of applied science a manual exists which is so widely disseminated and has met with such practically universal success. Among Wagner's other works are "Die Chemie" (1860; sixth edition 1873), "Theorie und Praxis der Gewerbe," 5 vols (1857-64), "Die chemische Fabrikindustrie," second edition (1869), "Regesten der Sodafabrikation" (1866), and "Studien auf der Pariser Ausstellung" (1868). The technical journals of the past thirty years contain numerous monographs from his pen on individual branches of chemical manufacture, full of valuable information and statistics obtained by Wagner from private sources, and replete with those fruitful suggestions natural to a mind familiar at once with the facts of science and with their widespread applications. Unquestionably Wagner's chief literary achievement is his celebrated "Jahresbericht über die Leistungen der chemischen Technologie." Started eight years after the appearance of Liebig and Kopp's well-known "Jahresbericht" for chemistry in all its departments, this work of Wagner's has for a quarter of a century kept the industrial and scientific world promptly, thoroughly, and accurately informed of the progress made in every branch of applied chemistry. In its fulness and exactness it is an admirable type of the annual review, now regarded as indispensable for every branch of human activity by the German mind, and the vast influence which it has exercised upon the development of chemical industries is impossible to measure. The "Jahresbericht" for 1879, recently issued, forms a portly volume of 1,300 pages, with over one hundred woodcuts, and in its reviews evidences at every step a critical spirit able to cope with the scientific and practical questions constantly evoked.

Personally Prof. von Wagner was of a most attractive disposition, admired by his students not only for his rare talents as a lecturer, but also for his amiable character. His loss is felt as severely in a widespread social circle as in the world of science T. H. N.

JAPAN[1]

II.

MISS BIRD'S work on Japan, as we have said, is cast in quite a different mould from that of Sir Edward Reed. With the exception of one or two chapters, she devotes her two volumes entirely to a record of her own experiences, casting them as in her well-known books on the Sandwich Islands and the Rocky Mountains, into the form of a series of letters. These have evidently been written in the midst of the experiences which they record, and this gives them a reality and a freshness which they could not have otherwise had. Her "Unbeaten Tracks in Japan" has all the best characteristics of her book on the Sandwich Islands. Indeed it seems to us that for the majority of readers it will have far more of novelty and quite as much interest as any of her previous works, while we doubt if any other book on Japan yet published gives so full and real an insight into the everyday life and the condition of the bulk of the people. Her work well deserves the title it bears. Many of the districts into which she, amidst all sorts of difficulties, succeeded in penetrating were certainly never before visited by a European woman, if indeed by a European of either sex. Sir E. Reed speaks of the people along parts of his route rushing out to see the "Chinese" pass; but so strange and literally uncouth did Miss Bird's appearance seem in some districts that the people could only set her down as an "Aino." She of course saw all the usual sights in the usual tracks, all that Sir Edward Reed saw; and for this her intimacy with Sir Harry Parkes and his universally beloved lady procured her every facility. The result is not the almost unmixed admiration which we find in Sir Edward Reed's volumes; but then it should be remembered that she was not the guest of the Japanese Government, but practically of the representative of the English Government, and although Miss Bird is a thoroughly independent observer, still her opinions may have taken somewhat of their colour from her special surroundings. She states fully both sides of the question of Japanese progress, and while giving full credit to the Government for the best intentions, and admitting that vast progress has been made in recent years, still she has many drawbacks to point out And no wonder; we fear that she, like some others who write on Japan, look for too much, and expect to find a Europe in the East, instead of a country struggling out of the bonds that swaddled it till only fifteen years ago. Still her criticisms are wholesome, and charitable, and good-natured, and we trust that they will come under the notice of those to whom, if taken in good part, they might be greatly beneficial. Miss Bird has much to say on the work of missionaries in Japan, but that is a subject into which we cannot enter here. She spent much of her time in the great centres among missionaries, and had ample opportunities of seeing the nature of the work they are doing. And her observations are of the greatest interest, and must be instructive to those who are hoping that the Japanese will ultimately put on the religious habiliments which have been shaped for centuries to the people of the West One unfortunate result we may mention, and that is the deterioration of the manners of those who have been long under missionary influence. Surely this is not necessary.

Of course the great interest of Miss Bird's book is connected with her solitary journey, quite unhampered by official guidance, north through the centre of the Main Island, and most of all her sojourn in Yezo among the strange remnant of people known as Ainos. Her journey

[1] "Japan its History, Traditions, and Religions, with the Narrative of a Visit in 1879." By Sir Edward J. Reed, K.C.B., F.R.S., M.P. Two vols. With Map and Illustrations. (London: John Murray, 1880.) "Unbeaten Tracks in Japan." By Isabella L. Bird. Two vols. With Map and Illustrations. (Same Publisher.) Continued from vol. xxii. p. 614.

through the Main Island gives us the other side of the picture to that seen in such well-known centres as Tokio, Yokohama, and Kioto—by far the finest city in Japan, the home of art and culture, according to Miss Bird. She gives very sad and sometimes very disgusting pictures of the condition of the people in some parts of the country through which she passed with her amusing and clever guide Ito. In one district the villages, she tells us, have reached the lowest abyss of filthiness; still she found the people here, as everywhere else, courteous, kindly, industrious, and free from gross crimes. Indeed, although naturally an object of intense interest wherever she went, and the centre of hundreds and sometimes thousands of eyes, she had rarely if ever to complain of discourtesy. Everywhere everybody was courteous and obliging, and except in the open towns, rarely was an attempt at extortion made. While part of the centre of the island is dreary enough, much of it is of the rarest beauty, with its fine mountains, rich woods, and rapid deeply cutting rivers. At Niigata and other open ports she notes with satisfaction the rapid spread of European medical treatment under the care of the medical missionaries, some of whom are doing excellent work. At Niigata, especially Dr. Palm's influence is wide-spread, and thousands of people have been weaned from the Chinese system of treatment, to that offered by Dr. Palm and his numerous native assistants, most of them men of the best type, who have established among themselves a society similar to some of the medical societies which meet in London and elsewhere. At Niigata Miss Bird made the acquaintance of an interesting bookseller "This bookseller, who was remarkably communicative, and seems very intelligent, tells me that there is not the same demand now as formerly for native works on the history, geography, and botany of Japan. He showed me a folio work on botany in four thick volumes, which gives root, stalk, leaf, flower, and seed of every plant delineated (and there are 400), drawn with the most painstaking botanical accuracy, and admirable fidelity to colour. This is a book of very great value and interest. He has translations of some of the works of Huxley, Darwin, and Herbert Spencer, which, he says, are bought by the young men attending the higher school. The 'Origin of Species' has the largest sale. This man asked me many questions about the publishing and bookselling trade in England, and Ito acquitted himself admirably as an interpreter. He had not a single book on any subject connected with religion."

In a letter from Kaminoyama, to the north-east of Niigata, she gives a graphic picture of the incongruities to be met with in the present transition state of the country:—"We rode for four hours through these beautiful villages on a road four feet wide, and then, to my surprise, after ferrying a river, emerged at Tsukuno upon what appears on the map as a secondary road, but which is in reality a main road twenty-five feet wide, well kept, trenched on both sides, and with a line of telegraph poles along it. It was a new world at once. The road for many miles was thronged with well-dressed foot-passengers, *kurumas*, pack-horses, and waggons either with solid wheels, or wheels with spokes but no tires. It is a capital carriage-road, but without carriages. In such civilised circumstances it was curious to see two or four brown-skinned men pulling the carts, and quite often a man and his wife—the man unclothed, and the woman unclothed to her waist—doing the same. Also it struck me as incongruous to see telegraph wires above, and below, men whose only clothing consisted of a sun-hat and fan, while children with books and slates were returning from school, conning their lessons."

As far north as Kubota, quite 200 miles north of Niigata, Miss Bird found a normal school established, with

Fig. 1.—Ainos of Yezo

twenty-five teachers and 700 pupils between the ages of six and twenty "They teach reading, writing, arithmetic, geography, history, political economy after John Stuart Mill, chemistry, botany, a course of natural science, geometry, and mensuration." Indeed she found evidence everywhere of the schoolmaster being abroad all over the country, and of the purpose of the Government to make education, after the models of Europe and America, universal and compulsory; and among the educated classes, the familiarity with the works of the most advanced English scientific writers—Huxley, Darwin, and Spencer especially—struck her greatly.

To the ethnologist Miss Bird's notes on the Ainos, the

aborigines of the Island of Yezo, and possibly of all Japan, will prove of special interest. We already know much about the physique and the habits of these strange people; but Miss Bird's notes of what she saw and heard during the weeks she lived in their houses, saw their daily life, heard what they had to say of themselves, their history, and their superstitions, are a real addition to our existing knowledge of them. As usual all sorts of things were said by people in Hakodaté to prevent her from trusting herself alone among these uncivilised people, but Miss Bird took her own womanly way, and was rewarded These Ainos she found of fierce outer aspect, with their long shaggy hair and beards, broad faces, and rough bodies, but in speech and manner gentler than the gentlest Hawaiian. Their soft and feminine speech constantly struck her, and in genuine politeness they are not surpassed by the Japanese. Here is a picture of Aino domestic life:—

FIG 2.—Aino Houses.

"I am in the lonely Aino land, and I think that the most interesting of my travelling experiences has been the living for three days and two nights in an Aino hut, and seeing and sharing the daily life of complete savages' who go on with their ordinary occupations just as if I were not among them. I found yesterday a most fatiguing and over-exciting day, as everything was new and interesting, even the extracting from men who have few if any ideas in common with me, all I could extract concerning their religions and customs, and that through an interpreter. I got up at six this morning to write out my notes, and have been writing for five hours, and there is shortly the prospect of another savage *séance*. The distractions, as you imagine, are many. At this moment a savage is taking a cup of *saké* by the fire in the centre of the floor. He salutes me by extending his hands and waving them towards his face, and then dips a rod in the *saké*, and makes six libations to the god—an upright piece of wood with a fringe of shavings planted in the floor of the room. Then he waves the cup several times towards himself, makes other libations to the fire, and drinks. Ten other men and women are sitting along each side of the fire-hole, the chief's wife is cooking, the men are apathetically contemplating the preparation of their food, and the other women, who are never idle, are splitting the bark of which they make their clothes. I occupy the guest seat—a raised platform at one end of the fire, with the skin of a black bear thrown over it."

These Ainos drink enormous quantities of *saké*, the national liquor of Japan; they can drink three times as much as a Japanese without being affected by it, and the drinking of it is with them the chief act of worship to the rude gods, if gods they be, which are stuck up in various parts of their huts. Here is another picture —

FIG 3—Ainos at home (From a Japanese sketch).

"About nine the stew was ready, and the women ladled it into lacquer bowls with wooden spoons. The men were served first, but all ate together. Afterwards *saké*, their curse, was poured into lacquer bowls, and across each bowl a finely-carved '*saké-stick*' was laid. These sticks are very highly prized. The bowls were waved several time with an inward motion, then each man took his stick and, dipping it into the *saké*, made six libations to the fire, and several to the 'god,' a wooden post, with a quantity of spiral white shavings falling from near the top."

The intense fondness of the Ainos for their children is a marked feature in their character, and the instantaneous and implicit obedience of the latter to their parents is as great as with the Japanese themselves. Their hospitality is genuine, universal, and almost profuse. "In every house the same honour was paid to a guest. This seems a savage virtue which is not strong enough to survive much contact with civilisation. Before I entered one lodge the woman brought several of the finer mats, and arranged them as a pathway for me to walk to the fire upon. They will not accept anything for lodging or for anything that they give, so I was anxious to help them by buying some of their handiwork, but found even this a difficult matter. They were very anxious to give, but when I desired to buy they said they did not wish to part with their things. I wanted what they had in actual use, such as a tobacco-box and pipe-sheath, and knives with carved handles and scabbards, and for three of these I offered 2½ dollars. They said they did not care to sell them, but in the evening they came saying they were not worth more than 1 dollar 10 cents, and they would sell them for that; and I could not get them to take more. They said it was 'not their custom.'"

All that Miss Bird tells us of her visit to the Ainos is well worth quoting; but we have space for only one more quotation, and that with reference to their physique —

"After the yellow skins, the stiff horse hair, the feeble eyelids, the elongated eyes, the sloping eyebrows, the flat noses, the sunken chests, the Mongolian features, the puny physique, the shaky walk of the men, the restricted totter of the women, and the general impression of degeneracy conveyed by the appearance of the Japanese, the Ainos make a very singular impression. All but two or three that I have seen are the most ferocious-looking of savages, with a physique vigorous enough for carrying out the most ferocious intentions, but as soon as they speak the countenance brightens into a smile as gentle as that of a woman, something which can never be forgotten. The men are about the middle height, broad-chested, broad-shouldered, 'thick-set,' very strongly built, the arms and legs short, thick, and muscular, the hands and feet large. The bodies, and specially the limbs, of many are covered with short bristly hair. I have seen two boys whose backs are covered with fur as fine and soft as that of a cat. The heads and faces are very striking. The foreheads are very high, broad, and prominent, and at first sight give one the impression of an unusual capacity for intellectual development; the ears are small and set low, the noses are straight, but short, and broad at the nostrils; the mouths are wide, but well formed; and the lips rarely show a tendency to fulness. The neck is short, the cranium rounded, the cheek-bones low, and the lower part of the face is small as compared with the upper, the peculiarity called a 'jowl' being unknown. The eyebrows are full, and form a straight line nearly across the face The eyes are large, tolerably deeply set, and very beautiful, the colour a rich liquid brown, the expression singularly soft, and the eyelashes long, silky, and abundant. The skin has the Italian olive tint, but in most cases is thin, and light enough to show the changes of colour in the cheek. The teeth are small, regular, and very white, the incisors and 'eye teeth' are not disproportionately large, as is usually the case among the Japanese; there is no tendency towards prognathism; and the fold of integument which conceals the upper eyelids of the Japanese is never to be met with The features, expression, and aspect are European rather than Asiatic.

"The 'ferocious savagery' of the appearance of the men is produced by a profusion of thick soft black hair, divided in the middle, and falling in heavy masses nearly to the shoulders. Out of doors it is kept from falling over the face by a fillet round the brow The beards are equally profuse, quite magnificent, and generally wavy, and in the case of the old men they give a truly patriarchal and venerable aspect, in spite of the yellow tinge produced by smoke and want of cleanliness. The savage look produced by the masses of hair and beard, and the thick eyebrows, is mitigated by the softness in the dreamy brown eyes, and is altogether obliterated by the exceeding sweetness of the smile, which belongs in greater or less degree to all the rougher sex

"I have measured the height of thirty of the adult men of this village, and it ranges from 5 feet 4 inches to 5 feet 6½ inches. The circumference of the heads averages 22·1 inches, and the arc, from ear to ear, 13 inches. According to Mr. Davies the average weight of the Aino adult masculine brain, ascertained by measurement of Aino skulls, is 45·90 ounces avoirdupois, a brain weight said to exceed that of all the races, Hindoo and Mussulman, on the Indian plains, and that of the aboriginal races of India and Ceylon, and is only paralleled by that of the races of the Himalayas, the Siamese, and the Chinese Burmese. Mr. Davies says, further, that it exceeds the mean brain weight of Asiatic races in general. Yet with all this the Ainos are a stupid people!"

The coast Ainos, Miss Bird tells us, she found had more hair on their bodies than those in the interior, and in some other respects differed in appearance, a difference probably to be accounted for by their mode of life and their surroundings. The Aino garments are often exceedingly handsome, being decorated with "geometrical" patterns in which the Greek fret takes part, in coarse blue cotton, braided most dexterously with scarlet and white thread. The modesty of the women is very remarkable, sometimes almost excessive even to European notions, nor do they seem to be the unmitigated drudges that most savage women are. The great hero of the Ainos is Yoshitsuné, who is also the most popular hero of Japanese history; the Ainos worship him, and Miss Bird was permitted to visit his shrine on a hill near Biratori, the Aino village at which she spent most of her time. He lived in the twelfth century, and was the brother of the Shôgun of the time, whose jealousy, according to some, compelled him to take refuge in Yezo. "None believe this more firmly than the Ainos themselves, who assert that he taught their fathers the arts of civilisation, with letters and numbers, and gave them righteous laws, and he is worshipped by many of them under a name which signifies Master of the Law I have been told by old men in Biratori, Usu, and Lebungé, that a later Japanese conqueror carried away the books in which the arts were written, and that since his time the arts themselves have been lost, and the Ainos have fallen into their present condition! On asking why the Ainos do not make vessels of iron and clay as well as knives and spears, the invariable answer is, 'The Japanese took away the books.'" This, combined with some other things which Miss Bird tells us of these Ainos, makes it seem quite possible that they are now a degenerate remnant of a people who formerly were comparatively cultured, and who may possibly have had "books" which the Japanese, their conquerors and masters, "took away." These strange people are certainly worthy of further study. The illustrations we are able to give, by the kindness of Mr. Murray, will give the reader some idea of their appearance and habits. We strongly recommend the reader to go to Miss Bird's volumes for further information of what she saw and heard while sojourning among them.

Again we commend these two works to all who desire to get, in comparatively short space, a very complete view of the past history and present condition of Japan.

BELL'S PHOTOPHONE

By the courtesy of Prof. Graham Bell we are at length able to do somewhat ampler justice to his latest discovery than has hitherto been possible. He has supplied us with certain details not hitherto published, and has also furnished us with drawings of his apparatus and experiments. Prof Bell is at present in Paris, and, as was mentioned in our columns last week, has there repeated some of his experiments.

Our readers are already aware that the object of the photophone is the transmission of sounds both musical and vocal to a distance by the agency of a beam of light of varying intensity; and that the first successful attempts made by Prof. Bell and his co-labourer, Mr. Sumner Tainter, were based upon the known property of the element selenium, the electric resistance of which varies with the degree of illumination to which it is exposed Hence, given a transmitting instrument such as a flexible mirror by which the vibrations of a sound could throw into vibration a beam of light, a receiver consisting of sensitive selenium forming part of an electric circuit with a battery and a telephone should suffice to translate the varying intensities of light into corresponding varying intensities of electric current, and finally into vibrations of the telephone disk audible once more as *sound*. This funda-

mental conception dates from 1878, when in lecturing before the Royal Institution Prof. Bell announced the possibility of hearing a shadow fall upon a piece of selenium included in a telephone circuit. The photophone, however, outgrew the particular electrical combination that suggested it; for not the least of the remarkable points in this research is the discovery that audible vibrations are set up in thin disks of almost every kind of

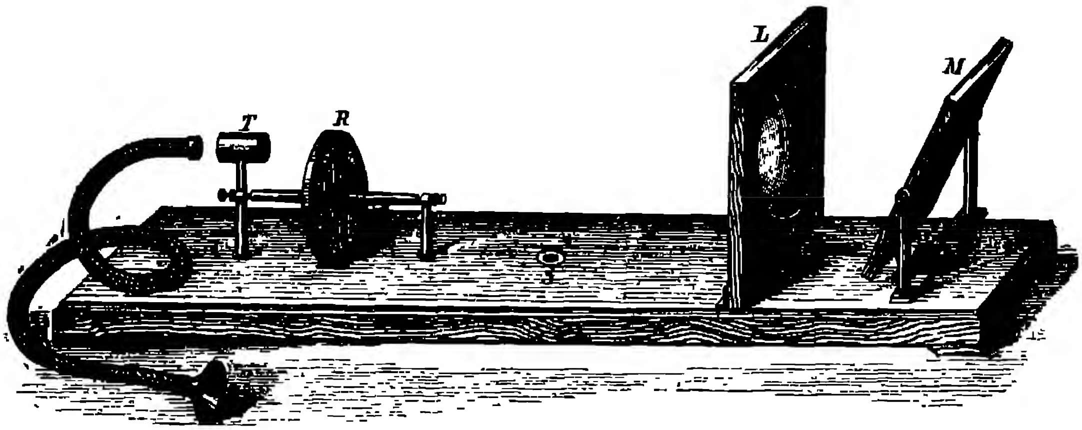


FIG 1.—The Musical Telephone

material by merely throwing upon them an intermittent light. Hence in theory, if not in practice, the receiver may be reduced to the divine simplicity of a mere disk of

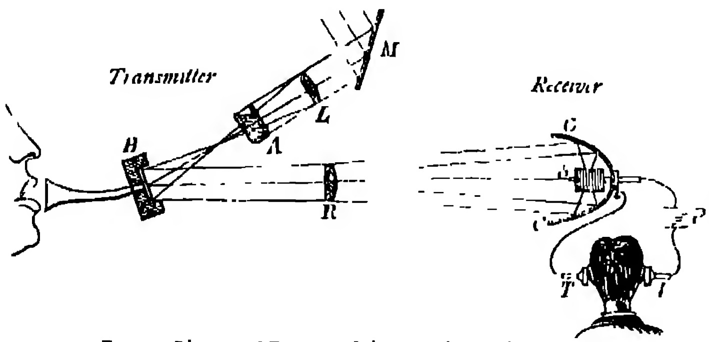

FIG 2.—Theoretical Diagram of the Articulating Photophone

vulcanite or of zinc, on one side of which the vibrating beam of light falls, and at the other side of which the hearer listens.

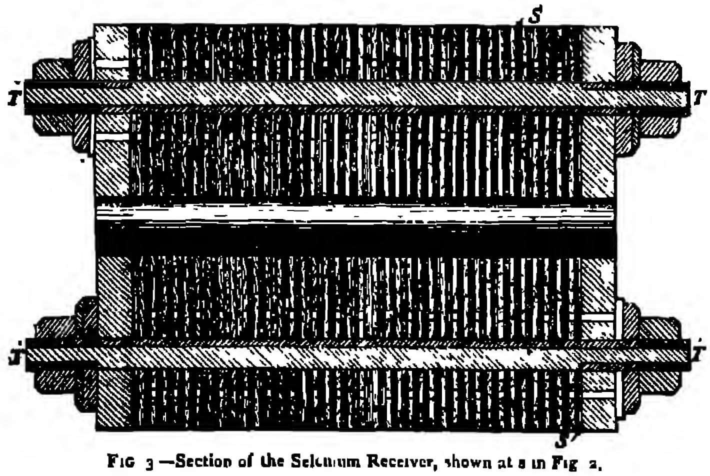

FIG 3.—Section of the Selenium Receiver, shown at s in Fig 2.

With the photophone, however, as with the telephone, there are instruments of different degrees of perfection. The original imperfect musical telephone of Philip Reis could only transmit musical tones, because it worked by rapid abrupt interruptions of the electric current; while the articulating telephone of Graham Bell was able to transmit speech, since by its essential construction it was able to send undulating currents to the distant receiving station.

We may in like manner classify the forms of photophone under two heads, as (1) articulating photophones, and (2) musical photophones; the former being able to transmit speech because they work by beams of light whose intensity can vary in undulatory fluctuations, like those of vocal tones; the latter being able to transmit simple musical tones only, since they work by mere interruptions of a fixed beam of light.

Up to the present time, Prof. Bell informs us, the simple receiving disk of ebonite or hard rubber has only served for a musical photophone: the reproduction of the tones of the voice by its means has not yet been demonstrated in practice—at least to his satisfaction. For while it produces unmistakable musical tones by the direct action of an intermittent light, in the experiments made hitherto with articulate speech the instruments have by necessity been so near to one another that the voice of the speaker was audible through the air. Under these circumstances it is extremely difficult to say whether the sounds that are heard proceed from the diaphragm, or whether they merely came through the air to the ear, and if they come from the diaphragm, whether they are really the result of the varying light, and not mere sound vibrations taken up by the disk from the speaker's voice crossing the air. Prof Bell hopes soon to settle this point, however, by an appeal to experiment on a larger scale with the receiving and transmitting instruments at greater distances apart, and with glass windows in between to shut off all sounds.

In Fig. 1 we illustrate the simple musical photophone of Bell and Tainter. It might perhaps be described without injustice as an *optical siren*, producing sounds from intermittent beams of light, as the *siren* of Cagniard de Latour produces them from intermittent puffs of air. A beam of light from the sun or from a powerful artificial source, such as an electric lamp, falls upon a mirror M, and is reflected through a large lens L, which concentrates

the rays to a focus. Just at the focus is interposed a disk pierced with holes—forty or so in number—arranged in a circle. This disk can be rotated so that the light is interrupted from one to five or six hundred times per second The intermittent beam thus produced is received by a lens T, or a pair of lenses upon a common support, whose function is to render the beam once more parallel, or to concentrate it upon the disk of ebonite placed immediately behind, but not quite touching them. From the disk a tube conveys the sounds to the ear. We may remind our readers here that this apparent direct conversion of light into sound takes place, as Prof. Bell found, in disks of all kinds of substances—hard rubber, zinc, antimony, selenium, ivory, parchment, wood, and that he has lately found that disks of carbon and of thin glass, which he formerly thought exceptions to this property, do also behave in the same way. We may perhaps remark without impropriety that it is extremely improbable that the apparent conversion of light into sound is by any means a direct process. It is well known that luminiferous rays, when absorbed at the surface of a medium, warm that surface slightly, and must therefore produce physical and molecular actions in its structure. If it can be shown that this warming effect and an intermediate cooling by conduction can go on with such excessive rapidity that beams of light falling on the surface at intervals less than the hundredth of a second apart produce a discontinuous molecular action of alternate expansion and contraction, then the mysterious property of matter revealed by these experiments is accounted for.

However this may be, the musical photophone, as represented in Fig. 1, produces very distinct sounds, of whose existence and dependence for their production on the light the listener may satisfy himself by cutting off the light at any moment with the little opaque disk fixed on the end of the little lever just in front of the holes in disk R, and which can be worked by a Morse key like a telegraph instrument, thus producing at will alternate sounds and silences. With this musical photophone sounds have been carried by an interrupted beam of light for a distance exceeding a mile, there appears, indeed, no reason why a much greater range might not be attained.

The articulating photophone is that to which hitherto public attention has been most largely directed, and in which a selenium receiver plays a part. Fig 2 gives in diagram form the essential parts of this arrangement A mirror M reflects a beam of light as before through a lens L, and (if desired for the purpose of experimentally cutting off the heat-rays) through a cell A containing alum-water, and casts it upon the transmitter B. This transmitter, shown again in Fig 5, consists of a little disk of thin glass, silvered on the front, of about the size of the disk of an ordinary telephone, and mounted in a frame, with a flexible india-rubber tube about sixteen inches long leading to a mouthpiece A second lens R, interposed in the beam of light after reflection at the little mirror, renders the rays approximately parallel The general view of the transmitting apparatus given in Fig. 5 enables the relative sizes and positions of the various parts (minus the alum-cell which is omitted) to be seen The screw adjustments of the support serve to direct the beam of light in the desired direction.

It may be well to explain once for all *how* the vibrations of the voice can affect the intensity of the reflected beam far away The lenses are so adjusted that when the mirror B is flat (*i.e.* when not vibrating) the beam projected from the apparatus to the distant station shall be nearly focussed on the receiving instrument. Owing to the optical difficulties of the problem it is impossible that the focussing can be more than approximate. Now, matters being thus arranged, when the speaker's voice is thrown against the disk B it is set into vibration, becomes alternately bulged out and in, and made slightly convex or concave, the degree of its alteration in form varying with every vibration of the voice Suppose at any instant —say by a sudden displacement such as takes place when the letter "T" is sounded—the disk becomes considerably convex, the beam of light will no longer be concentrated upon the receiving instrument, but will cover a much wider area Of the whole beam, therefore, only a relatively small portion will fall upon the receiving instrument, and it is therefore possible to conceive that, if perfectly adjusted, the illumination should be proportional to the displacement of the disk, and vary therefore with every vibration with the utmost fidelity

The receiver of the articulating photophone is shown on the right-hand side of the diagram (Fig. 2) sketched by Prof Bell A mirror of parabolic curve C C serves to concentrate the beam and to reflect it down upon the selenium cell S, which is included in the circuit of a battery P along with a pair of telephones T and T. Here again a general view like that given in Fig. 6 facilitates the comprehension of the principal parts of the apparatus The sensitive selenium cell is seen in the hollow of the parabolic mirror which is mounted so as to be turned in any desired direction. The battery standing upon the ground furnishes a current which flows through the selenium cell and through the telephones. When a ray of light falls on the selenium—be it for ever so short an instant—the selenium increases in conductivity, and instantly transmits a larger amount of electricity, and the observer with the telephones hears the ray, or the succession of them;—hears

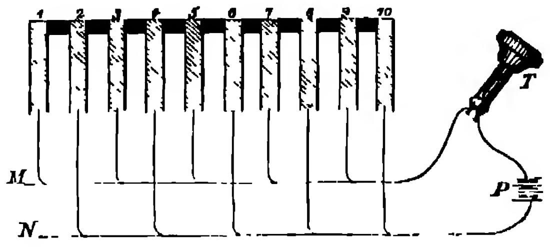

FIG 4—Diagram to show the action of the Selenium Receiver

indeed their every fluctuation in a series of sounds which, since each vibration corresponds to a vibration of the voice of the distant speaker, reproduce the speaker's tones

The great difficulty to be overcome in the use of selenium as a working substance arose from its very high resistance To reduce this to the smallest possible quantity, and at the same time to use a sufficiently large surface whereon to receive the beam of light, was the problem to be solved before any practical result could be arrived at After many preliminary trials with gratings and perforated disks of various kinds, Prof. Bell and Mr Tainter finally settled upon the ingenious device to be described A number of round brass disks, about two inches in diameter, and a number of mica disks of a diameter slightly less, were piled upon one another so as to form a cylinder about two and a half inches in length They were clamped together from end to end, the clamping rods also serving to unite the disks of brass electrically in two sets, alternate disks being joined, the 1st, 3rd, 5th, &c., being united together, and the 2nd, 4th, 6th, &c, being united in another series This done, the edges between the brass disks were next filled with selenium, which was rubbed in at a temperature sufficiently high to reach the melting-point of selenium After this the selenium was carefully annealed to bring it into the sensitive crystalline state. Then the cell is placed in a lathe and the superfluous selenium is turned off until the edges of the brass disks are bared. Fig. 3 shows, in section, the construction of such a cell Prof. Bell has also used cells in which the selenium filled only the *alternate* spaces between disks, the intermediate spaces being occupied by

mica disks of equal diameter with the brass disks. But this arrangement was in no way preferable, for in practice

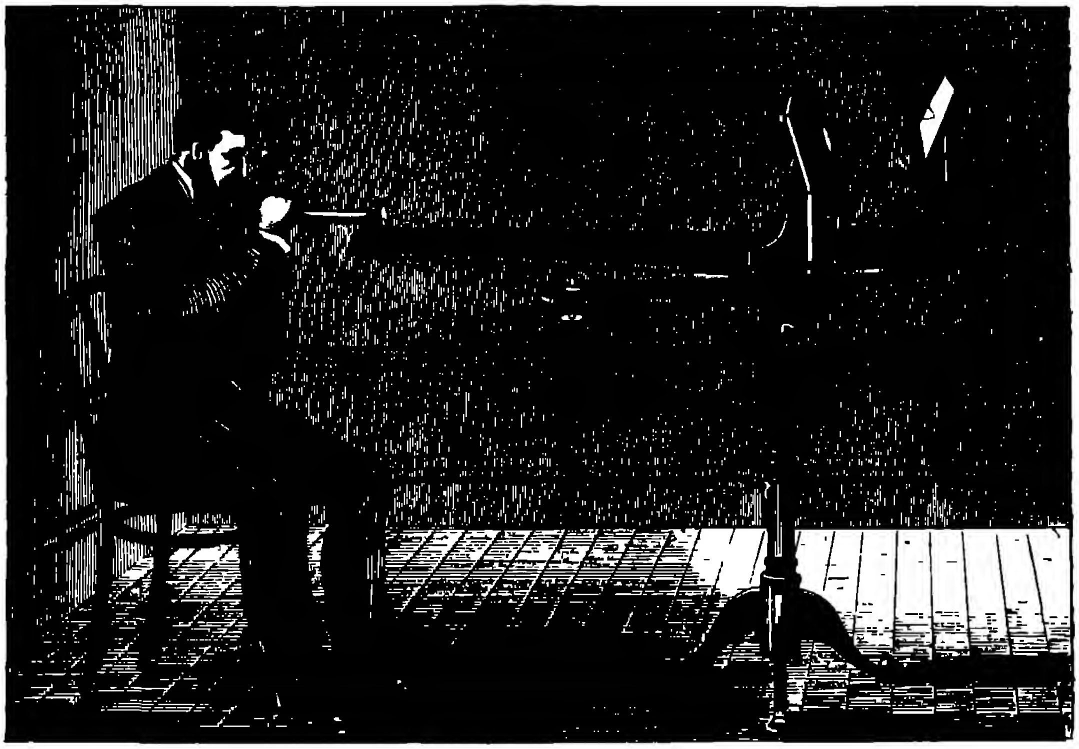

FIG. 5.—The Articulating Photophone. The Transmitter

it was found that moisture was apt to penetrate at the surface of the bare mica, spoiling the effect.

Fig. 4 is a diagram which simply illustrates the action of the selenium receiver, and shows, firstly, the way of

FIG. 6.—The Articulating Photophone. The Selenium Receiver

connecting the alternate disks; and secondly, that the current from the battery P cannot go round the telephone

circuit without passing somewhere through selenium from one brass disk to the next. The special advantages of the "cell" devised by Prof. Bell are that in the first place the thickness of the selenium that the current must traverse is nowhere very great; that in the second, this photo-electrical action of light on selenium being almost entirely a *surface* action, the arrangement by which all the selenium used is a thin surface film could hardly be improved upon, and that thirdly, the symmetry of the cylindrical cell specially adapts it for use in the parabolic mirror. These details will be of great interest especially to those who desire to repeat for themselves the experimental transmission of sound by light. The greatest distance to which articulate speech has yet been transmitted by the selenium-cell-photophone is 213 metres, or 233 yards.

When sunlight is not available recourse must be had to an artificial source of sufficient power During the recent experiments made by Prof. Bell in Paris the weather has been adverse, and the electric light has been called into requisition in the *ateliers* of M Biegnet (Fig 7, which is kindly supplied us by Prof. Bell). The distance in these experiments between the transmitting diaphragm B and the parabolic reflector C C of the receiver was fifteen metres, the entire length of the room in which

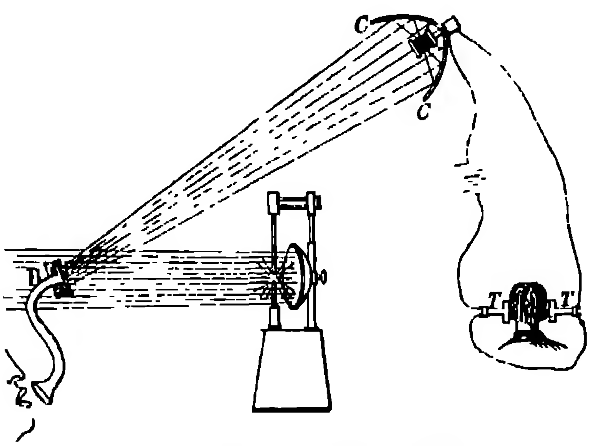

FIG 7—The Photophone with Electric Light

the experiments were made. Since at this distance the spoken words were themselves perfectly audible across the air, the telephones connected with the selenium-cell were placed in another apartment, where the voices were heard without difficulty and without doubt as to the means of transmission.

Of the earlier and less perfect forms of the photophone little need be said. One device, which in Prof. Bell's hands worked very successfully over a distance of eighty-six yards, consisted in letting the beam of light pass through a double grating of parallel slits lying close to one another, one of which was fixed, the other movable and attached to a vibrating diaphragm. When these were placed exactly one in front of the other the light could traverse the apparatus, but as the movable grating slid more or less in front of the fixed one more or less of the light was cut off. Speaking to the diaphragm therefore caused vibrations which shut or opened, as it were, a door for the beam of light, and altered its intensity. The mirror transmitter of thin glass silvered was however found superior to all others; and it is hard to see how it could be improved upon, unless possibly by the use of a thin disk of silver itself accurately surfaced and polished.

Whatever be the future before the photophone, it assuredly deserves to rank in estimation beside the now familiar names of the telephone and the phonograph.

NOTES

THE Triennial Gold Medal of the Chemical Section of the Philosophical Society of Glasgow, founded in commemoration of the work of Thomas Graham, F R.S., late Master of the Mint, will be awarded, at the end of the present session, for the best paper on any subject in pure or applied chemistry Authors are requested to send in their papers not later than February 1, 1881, addressed to the Secretary of the Section, Dr J J. Dobbie, Chemical Laboratory, University of Glasgow

THE annual meeting of the five academies which constitute the French Institute was held on Monday last week, when M. E. Levasseur gave an address on the Ethnography of France, and Col. Perrier described the operation he undertook to connect geodetically Algeria and Spain.

THE Royal Institution Lecture arrangements (not yet complete) for the ensuing season (before Easter) will include the Christmas course by Prof. Dewar, and courses by Professors Tyndall and Schafer, the Rev. William Haughton, the Rev. H. R. Haweis, Mr. H. H. Statham, Mr. Reginald S. Poole, and others Friday Evening Discourses will probably be given by Mr Warren De La Rue, Prof. Tyndall, Sir John Lubbock, Sir William Thomson, Dr. J Burdon Sanderson, Dr Andrew Wilson, Dr Arthur Schuster, Mr. Alexander Buchan, Dr. W H. Stone, Dr. W. J. Russell.

THE death is announced of Sir Thomas Bouch, the engineer of the Tay Bridge. It is believed that his system received a severe shock on account of the Tay Bridge disaster and the proceedings consequent on it.

M. ERHARD, the well known French cartographer, died on October 23 M. Erhard was a naturalised Frenchman, having been born at Freiburg im-Breisgau.

AMONG Mr. Stanford's announcements of forthcoming works are the following:—"Prehistoric Europe: a Geological Sketch," by Dr. James Geikie, F.R.S.; a fourth edition of "The Coal-Fields of Great Britain," by Prof. Edward Hull, F.R.S., "Life and her Children: Glimpses of Animal Life from the Amœba to the Insects," by Arabella B. Buckley, "Index Geographicus Indicus a Gazetteer of India," by J F Barness, "The Flora of Algeria, considered in Relation to the Physical History of the Mediterranean Region and Supposed Submergence of the Sahara," by W. Mathews, "Water Supply of England and Wales its Geology, Underground Circulation, Surface Distribution, and Statistics," by C E. de Rance.

IN the November number of *Scribner's Monthly* is a curious article on Second Sight or Clairvoyance, by an "Ex-Conjuror" (Mr Henry Hatton), in which it is shown that the whole thing is an elaborate system of mnemonics. The article has all the appearance of being genuine.

IN reference to the notice in NATURE, vol. xxii. p 587, on the address of Dr. Karl Zittel on the subject of the geology of the Libyan Desert, we should state that while the paper contains Zittel's opinions of the observations and collections of other travellers, it is mainly derived from the Professor's personal examination of the physiography of that country, and of the fossils which he there collected, when, as a member of the expedition under the leadership of Dr. Rohlfs, he visited the Libyan Desert in the winter of 1873-74

THE lecture on "The Modifications of the External Aspects of Organic Nature produced by Man's Interference," delivered by Prof. Rolleston to the Royal Geographical Society in 1879, has just been published in that Society's *Journal*. Amongst other interesting matters Prof. Rolleston rectifies an error into which all or most translators of Cæsar have fallen respecting

the Scotch fir. Cæsar ("De Bello Gallico," v. 12) says of Britain, "Materia cujusque generis, ut in Gallia, est *præter fagum atque abietem*," which words have been generally taken to mean, "There is wood of all kinds to be found in Britain, as in Gaul, *except* the beech and the fir." The word *præter* however does not always mean "except," but sometimes "besides," as quotations from Cicero and Plautus aptly illustrate. Prof. Rolleston further remarks that "an historian who was or was not a professed botanist, might without any sensible man blaming him, speak nowadays of all the common pines 'Scotch,' 'umbrella,' 'cluster,' &c., as 'pines'; my present belief is that Julius would similarly have spoken of them all as *abietes*, and would probably have included the 'firs' proper under the same name as these 'pines.'"

At the last meeting of the Epping Forest and County of Essex Naturalists' Field Club, held Saturday, October 30, it was announced that H.R.H. the Duke of Connaught, Ranger, had consented to become the Patron of the Club. Arrangements are being made to get up a course of winter science lectures in connection with the Club, the first of these being fixed for November 10, by Mr. J. E. Harting, who will lecture on "Forest Animals." It was further announced that a lecture had been promised during the session by Mr. A. R. Wallace.

Prof. Boyd Dawkins has lately shown in his "Early Man in Britain" that "although the Neolithic men were immeasurably above the Cave men in culture, they were far below them in the arts of design," and further that the Cave-man "possessed a singular talent for representing the animals he hunted, and his sketches reveal to us that he had a capacity for seeing the beauty and grace of natural form not much inferior to that which is the result of long-continued civilisation in ourselves, and very much higher than that of his successors in Europe in the Neolithic age." That this faculty of design or artistic aptitude is still independent of advanced or advancing civilisation is shown by Dr. Holub in a paper "On the Central South African Tribes," just published in the *Journal* of the Anthropological Institute. Mr. Holub remarks in connection with the Bushmen, that these people "regarded as the lowest types of Africans, in one thing excel all the other South African tribes whose acquaintance I made between the south coast and 10° south latitude. I have in my possession about 200 sketches on wood and stone and ostrich shells, by various tribes, but every one who knows anything about drawing must acknowledge that those which were done by Bushmen are superior to any of the others."

It is stated that some samples of a new seed and also of the native cucumber, collected in Central Australia by Mr. Vesey Brown, have been received at the Sydney Botanical Gardens. The former is a small black pea, which grows in pods similar to those of the ordinary pea, it is supposed to be edible, and resembles the nardoo. The cucumbers are about the size of walnuts, and are said to make an excellent pickle.

A recent report to the Foreign Office by Mr. Consul Crawford at Oporto on matters connected with the wine trade contains observations on the ravages of the parasitic insect, *Phylloxera vastatrix*, in the port wine district, and the means taken to avert them, and is illustrated by a sketch map of Northern Portugal, showing the progress of the disease.

At the opening meeting of the Eastbourne Natural History Society on October 15, Mr. F. C. S. Roper read a paper on the additions to the fauna and flora of the Cuckmere district during the past year.

In the Fourteenth Annual Report of the Aeronautical Society of Great Britain are papers on Aeronautics, by Mr. T. Moy, the "Mechanical Action of the Air," by Mr. Phillips; "Artificial Flight," by Mr. F. W. Brearey, "Aerial Propellers," by Mr. R. C. Jay.

Valparaiso advices to August 21 give particulars of the earthquake of August 14. The *Chilian Times* says:—"The duration of the shock was nearly ninety seconds. No serious damage was done to buildings in Valparaiso. At Vina del Mar, one of the towers of the church fell and another was shaken out of its level, and will probably have to be pulled down. The roof of the Quillota parish church fell in. At Llaillai eighteen or twenty houses were destroyed. Illapel suffered very severely. One strange item reported is the occurrence of 'huracane de agua,' whatever they may be. The Governor of Illapel in his first telegram stated that three of these had burst in the Cordillera. Now it is stated that there were thirty observed. One paper spoke of them as 'water volcanoes.' From Coquimbo it is reported that high columns of water were thrown up from the bay. An *employé* of the Transandine Telegraph Company felt the shock while crossing the highest parts of the Andes. He states that it was the strongest earthquake he has ever felt."

A Naples telegram of November 2 states that Vesuvius is now very active; lava continues to flow from the crater, and present indications point to the probability of increased eruptive energy.

The first meeting of the Society of Arts is announced for November 17, when the opening address will be delivered by F. J. Bramwell, F.R.S., Chairman of the Council. Before Christmas the following papers will be read:—November 24—"Barry's Influence on English Art," by J. Comyns Carr. December 1—"The Photophone," by W. H. Preece. December 8—"London Fogs," by Dr. A. Carpenter. December 15—"The Use of Sound for Signals," by E. Price Edwards. The following papers are down on the list for reading after Christmas:—"Buying and Selling: its Nature and its Tools," by Prof. Bonamy Price. "The Participation of Labour in the Profits of Enterprise," by Sedley Taylor, M.A., late Fellow of Trinity College, Cambridge. "The Gold Fields of India," by Hyde Clarke. "Flashing Signals for Lighthouses," by Sir William Thomson, F.R.S. "The Present Condition of the Art of Wood-carving in England," by J. Hungerford Pollen. "Ten Years' Experience of the Working of the Trade Mark Act," by E. C. Johnson. "Trade Prospects," by Stephen Bourne. "The Manufacture of Aerated Waters," by T. B. Bruce Warren. "The Compound Air Engine," by Col. F. Beaumont, R.E. "Improvements in the Treatment of Esparto for the Manufacture of Paper," by William Arnot, F.C.S. "Deep Sea Investigation, and the Apparatus used in it," by J. Y. Buchanan. "The Discrimination and Artistic Use of Precious Stones," by Prof. A. H. Church. "Indian Agriculture," by W. R. Robertson. Five courses of lectures are announced under the Cantor bequest. First course—Five lectures on "Some Points of Contact between the Scientific and Artistic Aspects of Pottery and Porcelain," by Prof. A. C. Church. Second Course—Three lectures on "Watchmaking," by Edward Rigg, M.A. Third course—Four lectures on "The Scientific Principles involved in Electric Lighting," by Prof. W. G. Adams, F.R.S. Fourth course—Three lectures on "The Art of Lace-making," by Alan S. Cole. Fifth course—Three lectures on "Colour Blindness and its Influence upon Various Industries," by R. Brudenell Carter. The two Juvenile Lectures, for children of Members, during the Christmas holidays, will be by G. J. Romanes, F.R.S., on "Animal Intelligence." The arrangements for the "Indian," "Foreign and Colonial," and "Chemical and Physical" Sections will be announced after Christmas.

The following is the title of the essay to which the "Howard Medal" of the Statistical Society will be awarded in November,

1881:—"On the Jail Fever, from the earliest Black Assize to the last recorded outbreak in recent times." The essays to be sent in on or before June 30, 1881. The Council have decided to grant the sum of 20*l.* to the writer who may gain the "Howard Medal" in November, 1881.

THE additions to the Zoological Society's Gardens during the past week include a Sykes's Monkey (*Cercopithecus albigularis*) from West Africa, presented by the Officers of the Royal Yacht, a Green Monkey (*Cercopithecus callitrichus*) from West Africa, presented by Mr. A. Haynes; a Rhesus Monkey (*Macacus erythræus*) from India, presented by the Rev. J. Saunders, B.A.; a Two-toed Sloth (*Cholopus didactylus*) from Demerara, presented by Mr. G. H. Hawtayne, C.M.Z.S.; an Egyptian Jerboa (*Dipus ægyptius*) from Egypt, presented by Major Money; a Common Trumpeter (*Psophia crepitans*) from Demerara, presented by Mr. J. Stovell; two Silver Pheasants (*Euplocamus nycthemerus*) from China, presented by Miss C. Hallett, an Indian Gazelle (*Gazella bennetti*) from India, deposited, an Ursine Dasyure (*Dasyurus ursinus*) from Tasmania, a Common Wigeon (*Mareca penelope*), a Grey Plover (*Squatarola helvetica*), a Knot (*Tringa canutus*), a Greenshank (*Totanus cadidris*), British, a Horned Ceratophrys (*Ceratophrys cornuta*) from Santa Marta, purchased.

OUR ASTRONOMICAL COLUMN

THE COMETS OF 1812 AND 1815.—We learn from M. Schulhof, of the Bureau des Longitudes, Paris, that in conjunction with M. Bossert he has undertaken a rigorous investigation of the orbit of the comet of 1812, which Encke showed to have a period of about seventy years, and which will consequently be again approaching its perihelion. M. Schulhof hopes to complete the calculations early in the ensuing year. He has discovered a series of original observations by Blanpain at Marseilles, which he considers to be amongst the best, if not the best series that are available; the original observations by Lindenau have also been received, but unfortunately nothing is to be found of the long series by Zach and Triesnecker. From the manuscripts preserved at Paris some corrections have been applicable to the results as printed. To this we may add that Flaugergues' differences of right ascension and declination from his comparison stars are published in the fifth volume of Zach's *Correspondance astronomique*. These observations of Flaugergues' at Viviers, and those made at Paris as they appear in the first folio volume, were reduced several years since by Mr. W. E. Plummer, now of the University observatory, Oxford, and from three very carefully formed normals he deduced a period of revolution about a year and a half shorter than that assigned by Encke in *Zeitschrift für Astronomie*, t. ii., so that the comet may now be expected at any time. At the instance of Prof. Winnecke sweeping ephemerides have been prepared by M. Mahn of Strassburg. It is however M. Schulhof's intention, on the completion of his investigation of the orbit, to furnish observers with ephemerides similar to those which have led to the re-discovery of several lost planets.

An able calculator at Vienna has nearly finished a new discussion of the observations of the comet of 1815 (Olbers' comet), which, according to Bessel's researches, is due at perihelion in February, 1887. This result may be materially changed by the more complete reduction of such series of observations as we possess in their original form, and a recomputation of the perturbations, with more accurate values of the planetary masses than were available at the date of Bessel's work.

CERASKI'S CIRCUMPOLAR VARIABLE STAR.—From the estimated magnitudes of Schwerd and Carrington, and Mr. Knott's epoch of minimum given in NATURE last week, the most probable period appears to be 2·49085d., to be reckoned from 1880, October 23·4672 Greenwich mean time. While the telescope is turned towards Ceraski's star, it may be suggested that Lalande 1013-4 in Cassiopeia should receive attention; at present we have the discordant estimates 10m. and 5m. of Lalande, 1790 September 29, and 1797 November 10 respectively, and 7·7 in the *Durchmusterung*; the star is 6m. on Harding's Atlas, and is not found in Fedorenko's catalogue, or in Argelander's zones; its position for 1880 is in R.A. 0h. 33m. 22s., N.P.D. 38° 46·8′.

THE LONGITUDE OF THE CAPE.—We understand that arrangements are being made for the telegraphic connection of the Royal Observatory, Cape of Good Hope, with Aden, which has already been connected with Greenwich, Mr. Gill taking an active part in the operation. The next desirable work of this kind will be the connection of an Australian observatory with the observatory at Madras, which is well-determined with reference to Greenwich.

GEOGRAPHICAL NOTES

COL. PREJEVALSKY writes from "Houi-de-Tin, plateau of the Hoang-ho, May, 1880." Having packed up and sent off all his collections to Alashan, he left his camp, 25 versts from the town of Donkyr, on March 20, to reach the Hoang-ho, 83 versts from Donkyr. Here the Yellow River turns abruptly from north-east to east, at the small valley of Gomi, inhabited by Tungut cultivators, and forming the extreme point of the habitable lands of the Hoang-ho. The river here is pretty wide, and has a very rapid current. The banks are wooded, with here and there pretty clumps of poplars and weeping willows. The river here is 8,000 feet above sea-level. After ten days at Gomi, Prejevalsky's party resumed their route. From Gomi the journey along the Hoang-ho was very difficult, the banks being deeply cut by steep ravines, which can only be noticed when close upon them. A stream usually flows at the bottom of these ravines, which are bordered by trees and wild arbutus. As soon as ever the party touched the Si-Fan territory a horseman appeared and, telling them they would soon be murdered, disappeared—a threat happily not realised. Indeed the Si-Fan became so reconciled to the presence of the intruders as to sell them butter and sheep. At 130 versts from Gomi they found in the ravines bordering the river vast forests frequented by innumerable birds, especially blue pheasants. The second local rarity was rhubarb, which was met with in prodigious quantities. The old roots of this plant reach colossal proportions. One of these roots, taken at hazard, weighed 26 lb. The mouth of the Churmysh, an affluent of the Hoang-ho, was reached 130 versts below Gomi, by the course of the river. Having examined the country for a distance of 40 versts, Prejevalsky was convinced that it was impossible to cross the enormous chain of mountains which extends along the Yellow River, the summits of which are lost in the clouds. Gaping ravines are met with at every verst, and there is not the least trace of vegetation, and therefore no forage for animals. He decided to return to Gomi. Thence he went to Houi-De, 60 versts on the south bank of the river, and sent his interpreter to Sinin to inform the local authorities that Prejevalsky wished to reach the mountain regions of eternal snow. The Amban of Sinin informed Prejevalsky that it was impossible to allow him to proceed to the Koko-nor, or to penetrate further into Houi-De, where there was a revolt of the Tunguts. Prejevalsky decided to spend the month of June where he was, exploring the fauna and flora, and afterwards go north towards Cheibsen, where he would remain during July, and complete his explorations in the mountains. The weather, he says, was detestable, cold and wet, with the thermometer sometimes 12° below zero C. He had collected 250 specimens of plants, 500 species of birds, and many of fish. The geography of the country traversed had, moreover, been observed and noted, astronomical, barometrical, and thermometrical observations made, and sketches taken of the various types of natives. He doubts much whether the Hoang-ho makes the enormous curve represented in maps, he did not observe any such curve in the 250 versts explored by him. He expected to reach Alashan about August 20.

IN the Geographical Society's *Proceedings* for November Mr. C. R. Markham supplies a brief but lucid account of Lieut. Schwatka's expedition to King William Land, and of the previous state of our knowledge respecting the remains, &c., of the Franklin Expedition, and he arrives at the conclusion that we have gained but little by this last attempt to obtain information beyond that gathered by Sir L. McClintock. Lieut. Schwatka's journey, however, he considers to have been a most remarkable one, and in some respects without a parallel. Dr. Christison follows with a paper descriptive of a journey made some twelve years ago to Central Uruguay. The geographical notes are numerous this month, and furnish much useful information, especially in regard to Africa. Under the head of "Corre-

spondence" we find letters by Adm. R. C. Mayne on a possible communication between Skyring Water, Straits of Magellan, and Smyth's Channel, and by Capt. Alexanderson on the subject of some observations made during a recent voyage along the Loango Coast of West Africa. The maps given this month are of King William Land and the Estancia de San Jorge, Uruguay, with a small inset map of the whole republic.

As we announced last week, the Vienna Geographical Society has issued an appeal for subscriptions for an Austrian expedition, which Dr. Emil Holub has decided on undertaking. Dr. Holub intends crossing the whole length of Africa from south to north. He will start from the Cape of Good Hope and penetrate to the Zambesi, thence explore the Maruthemambunda territory, the watershed district between the Zambesi and the Congo, visit the lake sources of the Congo, and from there through Darfur he will try to reach Egypt Dr. Holub expects the journey to extend over three years. The expenses, he reckons, will amount to about 50,000 florins, 5000 of which he can himself supply.

Lord Aberdare will preside at the first meeting of the Geographical Society next Monday evening, when Mr Jos. Thomson, the Commander of the East African Expedition, who has lately returned from Zanzibar, will give an account of his journey to the Lukuga outlet of Lake Tanganyika, *viâ* the head of Lake Nyassa. Mr. Thomson's paper promises to be unusually interesting, as the country traversed by him was for the most part previously unexplored.

Another African traveller, Mr. James Stewart, C.E., has just returned to England from Livingstonia, Lake Nyassa Mr. Stewart, it will be remembered, also crossed the unknown belt of country between Lakes Nyassa and Tanganyika by a different route, for the most part, from Mr. Thomson's, and arrived at the south end of the latter lake only a day or two after him

In the November number of their *Chronicle* the London Missionary Society publish a full account of Dr Southon's interview with Mirambo on the subject of the murder of Messrs. Carter and Cadenhead, and the main facts elicited by him appear to exonerate that chief from any direct share in the unfortunate occurrence Mohammed, Capt. Carter's servant, succeeded in saving the journals of both Carter and Cadenhead, and all the most important manuscripts and letters of the former.

The Baptist Missionary Society hope to publish in the December number of their *Herald* an admirable map which they have just received from the Rev. T J. Comber of their Congo Mission, who has been for some time stationed at San Salvador. It is stated to be very carefully drawn to scale, and to exhibit the many and important discoveries made by the missionaries in their various journeys towards Stanley Pool; it will also show the relative positions of the various towns to Banana, Mboma, San Salvador, Makuta, and other important centres

The new *Bulletin* of the Antwerp Geographical Society contains papers by M. Bernardin on the Fiji Islands, their resources, progress, &c., and by Dr. L Delgeur, vice-president of the Society, on cartography among the ancients.

We have received from Danzig an excellent little guide-book to that city, with special reference to the scientific and medicinal points of interest of the town and district, compiled from the recent meeting of the German Association. It is a model of its kind, and contains an admirable series of special maps.

Doctors Rohlfs and Stecker have left Suez for Massowah and Abyssinia.

In the *North American Review* are appearing M Desiré Charnay's notes of his exploring work in Mexico. The November number contains the third instalment.

KEW GARDENS REPORT

From the just-issued "Report on the Progress and Condition of the Royal Gardens at Kew" for 1879 we take the following items:—

Some idea of the magnitude of the destruction caused by the hailstorm of August 3, 1879, may be obtained from the fact that the number of panes broken was 38,649, and the weight of broken glass eighteen tons. The plantations along the Grass Avenue skirting the river have all been greatly improved, very poor specimens removed and replaced by Holm oaks, which will eventually render the avenue practically an evergreen one. This portion of the grounds suffers greatly from the unconsumed smoke of the gas-works and manufactories at Brentford, which is not only most prejudicial to the plants, but so blackens the labels that they become illegible in a few years. Some interesting notes are given on the cultivation of the various kinds of india rubber. According to Hecht, Levis, and Kahn's Report for 1879, Para rubber (*Hevea*) is still the largest source of supply. The total import into England during the year was 4651 tons. Liverpool received 25 tons of Ceará Scrap rubber and 900 tons of African (*Landolphia*), while London imported 350 tons from Assam (*Ficus elastica*), 250 tons from Borneo (*Willughbeia*), and 550 from Mozambique (*Landolphia*). Considerable attention has been paid at Kew during the past year to the examination of the African Landolphias and Malayan rubber-yielding Willughbeias, and the results will be given in the next report Additional facts to those contained in the previous Report are given on the introduction of South American species into the Old World. From Singapore Mr. Murton reports:—"The plants of Hevea and Castilloa in the gardens are now large plants, but hitherto propagation from the strong growths they are making seems rather difficult, whereas they used to propagate freely from the weak wood produced while in pots.' Preparations are being made in Burma for the cultivation of Ceará Scrap (*Manihot glaziovii*), while Dr. King reports that the Ceará rubber promises to grow well in Calcutta; seeds have been distributed to various parts of India, and the plant seems to thrive well in Upper India. Singapore does not seem to suit Ceará Scrap, according to Mr. Murton, while at Zanzibar it yields seed most abundantly, but the seeds are slow to germinate. At Zanzibar the Pará rubber is a less quick grower than the Ceará and does not branch. At Mergui eight Pará trees, the survivors of a batch of seedlings received from Dr. King in 1877, continue to do well in the office compound. At Calcutta, according to Dr. King, Pará rubber continues to be as disappointing as ever; he believes it is useless to try it anywhere except in the south of Burma or the Andamans, and perhaps in Malabar Mr. Jenman reports that the atmospheric conditions in Jamaica appear favourably adapted to the Pará rubber. Equally important information is given as to the cultivation of mahogany in the Old World. On this the Report says. "This may now be regarded as an accepted success. The tree grows well in many parts of India and in Ceylon, and in the former there is a local demand for the wood In this country new uses are found for it, one of the most recent being for the linings and panellings of railway carriages instead of teak, which is now exclusively used for ship building. It is not easy to see any valid arguments against the cultivation of a tree the timber of which is of admitted excellence for a variety of purposes and the growth of which is apparently attended with little difficulty. As late as 1876 the Government of Bengal was adverse to mahogany planting. This policy has now, however, been modified, and in his report for 1878–79 Dr. Brandis, the Inspector-General of Forests, reports: 'Of the exotic trees which are cultivated by way of experiment mahogany is the most important, and its success seems not improbable, though it is too early yet to form final conclusions upon the subject.' Mahogany is also cultivated as an experiment in Burma and the Chittagong district of Bengal. The tree is known to thrive well near Calcutta, and every effort should be made to cultivate it in those forest districts where climate and other circumstances are favourable" Experiments are being made in Queensland, and favourable reports come from Saharunpore and Singapore. Some curious notes are contained in the Report on Chestnut Flour. "We are indebted to Mr. D. E. Colnaghi, H B M 's Consul at Florence, for specimens of the dried chestnuts, flour, and *necci* (the cakes made from them), which are so important an article of subsistence in the Apennines The collection of the specimens for Kew was due to the kindness of Dr. L. Bacci of Castigliano, in the mountains of Pistoja. The fresh chestnuts are dried, or rather roasted, for three days and nights in a *seccatoio*, or drying room, on a latticed floor covering a chamber in which a fire is lighted. The husk is then easily removable, and the kernel is ready to be ground into flour, which is of a pinkish colour. This is mixed to the consistence of cream with water, and poured on fresh chestnut leaves to be baked into small circular cakes, *necci*, between heated stones. The collection having been divided between the museum of the Royal Gardens and the Food Collection, Bethnal Green, Prof. Church, who has charge of the latter, has obligingly furnished us with the following analysis of the flour:—

Moisture	14·0
Oil or fat	2·0
Proteids	8·5
Starch	29·2
Dextrin and soluble starch	22·9
Sugar	17·5
Cellulose, &c.	3·3
Ash	2·6
	100·0

The cakes were found to contain only 6·7 per cent. of proteids, with 3·4 per cent. of flour. The large amount of dextrin is due to the high temperature to which the chestnuts are subjected in the process of drying Prof. Church thinks that chestnut-flour ought to be of easy digestibility, and a suitable children's food, considering that it contains over 40 per cent. of nutritious matters soluble in pure water The Museum of the Royal Gardens is indebted to Mr. George Maw for a specimen of a product used, according to the Rev. Wentworth Webster, who procured it, as tea in the Basses Pyrenées in France, and on the Spanish side of the Pyrenées in Navarre. It was found to consist of the dried shoots of a species of *Lithospermum*, which was identified with probability as *L officinale*." Mr. Noble advocates the cultivation of rye straw (*Secale cereale*) as a paper material, not inferior to esparto. Mr. W L. Booker, H.M.'s Consul at San Francisco, sent some specimens of a scented wood from the highlands of Mexico, known as Lin-a-Loa, and which has been identified with a wood already in the Kew Museum, and which appears to be yielded by a species of *Bursera*. Further material in the shape of dried specimens, with both fruit and flowers, is much to be desired for the purpose of ascertaining definitely the tree which produces it. The name Lin-a-Loa is clearly a corruption of Lign Aloes, which has been identified with *Aquilaria agallocha*, otherwise known as eaglewood (Kew Report, 1878, p. 36). This is however a tree confined to the Old World, and the Mexican one has no connection with it. The wood of the latter is imported into this country for manufacture into perfumery, a fragrant oil known as otto of linaloe being distilled from it. On the interesting Chinese timber-tree known as the Nan-mu-tree, and referred to in the Report for 1877, some information has been obtained from Mr. Baber:—"Two days' journey south-east of Chungking in Szechuen I found several specimens of about a foot in diameter, one of them having a straight branchless trunk of 100 feet in height, with the branches and foliage rising 25 feet above that, another had 70 feet of bare straight stem, and 90 feet of total altitude. Although the trunks are branchless, yet in many cases they send out shoots resembling saplings, which rise parallel with the trunk. The wood is white and close-grained, and I do not believe that the pillars at the Ming tombs near Peking are of this wood. They look more like true teak. I have seen some much larger trees than the above, some two feet and more in diameter, straight and of great altitude. They are used in Szechuen for bridge work." Eventually, through the instrumentality of Père Vincot, who resides at Chungking, flowering specimens were transmitted to the Kew Herbarium From these a figure has been prepared, and they entirely confirm the previous identification of the tree by Prof Oliver (from the leaves alone) as a near ally of *Phœbe pallida* (one of the laurel family). The genus *Phœbe* is now merged in *Persea*, and Prof. Oliver has described the Nan-mu under the name of *Persea nan-mu*, distinguishing it from *Persea* (*Phœbe*) *pallida* "chiefly in stature, in the form of the acumen of the leaves and the character of the indumentum." On a block of Pai-chai wood sent by Mr. W. M. Cooper, H.B M.'s Consul at Ningpo, Mr. R. J. Scott reports:—"The most striking quality I have observed in this wood is its capacity for retaining water and the facility with which it surrenders it. This section, which represents one-tenth of the original piece, weighed 3 lbs. 4½ ozs. At the end of twenty-one days it had lost 1 lb 6¾ ozs. in an unheated chamber. At the end of another fourteen days, in a much elevated temperature, it only lost ½ oz. In its present state of reduced bulk its weight is 1 lb. 10 ozs. It is not at all likely to supersede box; but it may be fit for coarser work than that for which box is necessary." The principal researches conducted in the laboratory during the past year have been those of Mr. Marshall Ward, on the development of the embryo-sac, published in the *Journal* of the Linnean Society, vol. xvii. pp 519–546, Prof. Church, continued investigation on albinism in leaves, published in the *Journal* of the Chemical Society, January, 1880. The laboratory has also been employed for the experimental demonstrations given to the *employés* of the Royal Gardens, and for the examination of the University of London for the degree of Doctor of Science in the subject of physiological botany

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

OXFORD.—The examinations for the degree of Bachelor of Medicine will commence in the medical department of the Museum as follows:—

The First (Scientific) Examination) November 29.

The Second (Final) Examination, December 6.

Candidates for either of these examinations, and candidates for the certificate in Preventive Medicine and Public Health are requested to send in their names on or before November 15 to the Regius Professor of Medicine at the Museum.

The University of Oxford Commissioners have given notice that all new scholarships and exhibitions granted by the Colleges shall be subject to the provisions of any new statutes which may be made by the Commissioners in relation to the length of tenure and emoluments of such scholarships and exhibitions.

The University Commissioners at present sitting have forwarded to the Hebdomadal Council six proposed statutes which they contemplate making, subject to any representation which they may receive from the Council on the appointment and duties of University Professors and Readers. The proposed statutes include certain general regulations applicable to the whole Professoriate Each Professor must reside six months in each year between October 1 and the ensuing July 1 Each Professor, besides his regular course of lectures, must give one public lecture every year Each Professor must give private instruction to students in matters relevant to the subject of his lectures, and must examine the students who have attended his lectures at the end of each course.

The following are the particular regulations applicable to the Savilian Professor of Astronomy, the Professor of Experimental Philosophy, the Waynflete Professor of Chemistry, the Linacre Professor of Human and Comparative Anatomy, the Waynflete Professor of Physiology, and the Wykeham Professor of Physics. Section 7 relates to the three proposed new professorships.

(1) The Professor shall deliver one course of fourteen lectures at least in each of two out of the three University terms (Easter and Trinity Terms being counted as one), every course shall extend over seven weeks at least, and not fewer than two lectures shall be delivered in each week.

(2) He shall be ready to give the private instruction required by the General Regulations on two days in each week in which he lectures, and during one hour at least on each of such days

(3) The laboratory under the charge of each Professor, and, in the case of the Savilian Professor of Astronomy, the University Observatory, shall be open for eight weeks in each term (Easter and Trinity Terms being counted as one), and at such other times, and for such hours, as the University may by statute determine

Students shall be admitted to the University Observatory and to the laboratory under the charge of each Professor, upon such conditions as the University shall from time to time by statute determine, and upon the terms of paying such fees, not exceeding such amount as may be fixed by any statute of the University in force for the time being, as the Professor may from time to time require.

(4) Except for some grave reason to be approved by the Vice Chancellor, the Professor shall, for seven weeks in each term (Easter and Trinity Terms being counted as one), and during some part of three days in each week, be ready to give instruction in the subjects of his Chair to such students as shall have been admitted to the laboratory under his charge (or, in the case of the Savilian Professor of Astronomy, to the University Observatory); and such instruction shall be given in the laboratory or observatory (as the case may be) or in some class-room connected therewith

(5) The Professor shall also, at the close of each term, inform any college which may request him to do so as to the regularity of attendance and the proficiency of the students belonging to such college who have been admitted into the laboratory or observatory under his charge, and shall give like information, if requested, to the delegates of students not attached to any college or hall.

The Particular Regulations next following shall be applic-

able to the several Professors named in them respectively (that is to say):

(1) The Savilian Professor of Astronomy shall have the charge of the University Observatory, and shall undertake the personal and regular supervision of the same, and of the several demonstrators and other assistants employed therein, and shall be responsible for all the work carried on there.

(2) The Professor of Experimental Philosophy shall have the charge of the Clarendon Laboratory, and shall undertake the personal and regular supervision of the same, and of the several demonstrators and other assistants employed therein, and shall be responsible for all the work carried on there.

(3) The Waynflete Professor of Chemistry shall have the charge of the Chemical Laboratories in the University Museum, or such part thereof as the University may by statute assign to him, and shall undertake the personal and regular supervision of the same, and of the several demonstrators and other assistants employed therein, and shall be responsible for all the work carried on there.

(4) The Linacre Professor of Human and Comparative Anatomy shall have the charge of the Anatomical and Ethnological Collections and the Anatomical Laboratories in the University Museum, or such part thereof as the University may by statute assign to him; and shall undertake the personal and regular supervision of the same, and of the several demonstrators and other assistants employed therein, and shall be responsible for all the work carried on there.

(5) The Professor of Botany and Rural Economy shall have the charge and supervision of the Botanical Gardens and Botanical Collections belonging to the University, and it shall be part of his duty to make such Gardens and Collections accessible to, and available for, the instruction of students attending his lectures

(6) The Professors of Geology and Mineralogy respectively shall have the charge and supervision of the Geological and Palæontological Collections, and of the Mineralogical Collection, belonging to the University, and it shall be part of their duties to make such collections respectively accessible to, and available for the instruction of, students attending their lectures.

(7) { The Professor of Classical Archæology,
The Wykeham Professor of Physics, and
The Waynflete Professor of Physiology,

shall, in like manner, if the University by Statute shall think fit to charge them therewith, undertake the charge of any collections or laboratories connected with the subjects of their respective Chairs, which the University may from time to time assign to them, and shall have similar duties in respect thereof.

(8) The several Professors named in the foregoing particular regulations shall in the performance of the duties committed to them by such regulations be subject to the statutes of the University for the time being in force in that behalf

This Statute is proposed to be made by the University of Oxford Commissioners under the Universities of Oxford and Cambridge Act, 1877, for the University.

SOCIETIES AND ACADEMIES

PARIS

Academy of Sciences, October 26.—M. Wurtz in the chair —The following papers were read .—On attenuation of the virus of chicken-cholera, by M. Pasteur If the most virulent virus (to be got from a fowl which has died of the chronic form of the disease) be taken and successive cultivations made of it in the pure state, in bouillon of fowl's muscles, the interval of time between one sowing and another is found to affect the virulence. With intervals up to one month, six weeks, or two months, no change of virulence is noted, but as the interval is enlarged the virus is found to become weaker. The attenuation does not take place with mathematical regularity. No change can be detected in the microscopic organisms to account for the changes in its power. But M. Pasteur shows by experiments (in which some bouillon, to which a little strong virus had been added, was inclosed and kept some time in sealed tubes) that it is probably the oxygen of the air that attenuates the virulence. May it not then also affect other kinds of virus?—Experimental study of the action of the organism of sheep, more or less refractory to splenic fever, on the infectious agent; what becomes of specific microbia introduced directly into the circulation by large transfusions of anthracoid blood, by M. Chauveau. After such transfusion into animals whose resistance to the disease is considerable and strengthened by preventive inoculation, the bacterian rods soon disappear from the blood (in a few hours one cannot find them). They are not destroyed, however, but are arrested in the capillary system of the lungs and of other parenchymatous organs, where they may be found with retained vitality when the transfusion has been rapidly fatal. When the animal survives more than three days the bacteria disappear from the lung and the spleen (as well as the blood), and health may be regained One region alone proves favourable to maintenance and development of the bacterian life, viz., the surface of the brain (pia mater), and the development there has quite special characters (elongation and inflexion of the rods and appearance of spores), resembling those which belong to artificial cultivations. The infectious activity of these bacteria of the pia mater is considerable.—On linear differential equations, by M. Appell —The Secretary announced the opening of a subscription for erection of a monument to the memory of Spallanzani in his native town.—On the class of linear differential equations, with rational coefficients, the solution of which depends on the quadrature of an algebraic product which contains no other irrationality than the square root of an entire and rational polynome, by M. Dillner.—Photography of the nebula of Orion, by Prof Draper.—Application of selenium to the construction of a photo-electric regulator of heat for the burning in of stained glass windows, by M. Germain. As far as possible from the muffle furnace is placed a dark chamber closed by a parabolic reflector, the focus of which is in the axial line of the telescope commonly used. At this focus is a ball of selenium between two cups of brass, leaving a zone of selenium visible. One cup is connected by German silver wire to a thermo-electric pile (of thirty elements), adapted for strong heat and exposed to that of the muffle, and the pile is connected (by the other poles of its elements) to the side of a stoppered porous vessel filled with water, ensuring a sensibly constant temperature on that side. The thermo-electric current increases with the temperature, and while the part of the muffle covered by the telescope remains dark, the selenium does not effectively alter in resistance, but when a cherry-red tint is reached (indicating time to stop), the resistance of the selenium is reduced about a fourth. The current gains strength and sounds a bell, or affects a system whereby the fuel is diverted (With the pile is connected a galvanometer, a condenser, and other secondary arrangements.) —On some modifications undergone by glass, by M Salleron. He calls attention to the corrosion, deformation, and fracture of areometers used in sugar-works which treat molasses by osmose; where the instruments are kept several days in a liquid at 95°, of density, 1014 (2° B), and containing sugar 115 gr., ash 91 gr ; total 206 gr. per litre. The ash consists of chloride of potassium and organic salts of potash. The cracks are all more or less spiral in form.—Influence of light on germination, by M. Panchon. He measured the quantities of oxygen absorbed during germination by identical lots of seeds. Light (he finds) accelerates the absorption in a constant manner; the advantage in favour of light being from a fourth to a third of the quantity absorbed in darkness. The degree of illumination is relative to the quantity absorbed The respiratory acceleration in seeds illuminated by day persists for several hours in the darkness. The accelerative influence of light is more intense at low temperatures.

DR. SIEMENS'S NEW CURE FOR SMOKE

THE growing obscurity which distinguishes the winter atmosphere of London has disposed men to consider whether it is an indispensable evil connected with the use of coal in great centres of population, or whether means can be found of providing the warmth and comfort which the copious use of mineral fuel affords us without having to pay the penalty of dispensing with the solar ray, of finding ourselves and everything we touch covered with soot, and of occasionally having, even at midday, to grope our way with a feeling akin to suffocation.

I am decidedly of opinion that the evil is one which not only admits of remedy, but that its cure would result from a closer attention to the principles of economy in the use of fuel

Until within recent years wasteful expenditure was the rule both in the application of fuel to our large manufacturing operations and for domestic purposes, but great strides have been made within the last twenty years to improve our mode of burning fuel both under our steam boilers and in the metallurgical furnace. The Regenerative Gas Furnace, which was the subject of Faraday's last discourse at the Royal Institution in 1862 has contributed its share to this result, combining as it does considerable economy, with the entire absence of smoke from the chimney.

Since by the employment of gaseous fuel results such as these are realised, there seems no *à priori* reason why analogous results should not attend its application on a smaller scale, even down to the means of heating our apartments, which, although a small application in each individual instance, amounts, in the aggregate, to the largest of all the uses of mineral fuel.

Gas-grates have been tried by individuals desiring progress, but I know several instances in which on account of the great comparative expense incurred, and objections raised to the smell, and dry heat, as it is called, in the room, the time-honoured smoky but cheerful coal-fires were reinstated.

A gas-grate that was arranged in my billiard-room in the usual fashion, consisting of three air-gas-pipes with apertures distributed over the fire-grate, and covered with pumice-stone, presented certainly a cheerless appearance, and filled the room (notwithstanding a fair chimney-draught) with fumes, rendering the benefit of the fire a doubtful one. These fumes could not have passed into the room from the upper surface of the pumice-stone owing to its proximity to the chimney, but a little consideration made me come to the conclusion that these gases really proceeded from the ash-pan into the room The products of combustion set up by the gas flames ascend no doubt so long as they are intensely hot, but in giving off their heat to the inert pumice-stone they rapidly cool, and being heavier than atmospheric air, descend through the grate between the lines of gas flames, and thus reach the apartment. Moreover the gas burnt towards the back of the fireplace takes scarcely any part in providing a red radiating surface in front of the grate, serving only to baffle the draught passing towards the chimney from the room

The first condition to be realised in an efficient gas-grate consists in suppressing all gas orifices except immediately behind the bottom front bar, and in substituting for the grate a solid dead plate Instead of using inert matter such as pumice-stone, I consider it far more economical and efficacious to transfer the heat of the gas flames to gas coke or anthracite, which when once heated helps the gas to increase and maintain a sufficient temperature for radiation through its own slow combustion. The gas should not be mixed in the pipe with atmospheric air to produce a Bunsen flame, as is frequently done, because by using the unmixed gas a rich flame is set up between the pieces of coke near the front of the grate, producing to the eye an appearance similar to a well-ignited ordinary coal fire, and the hot carbonaceous matter through which it percolates ensures its entire combustion before reaching the chimney Heat will however gradually accumulate towards the back of the fire, notwithstanding the suppression of the grate bars, and in order to obtain the utmost economy this heat should be utilised to increase the temperature of the gas flames and of the coke in front of the grate

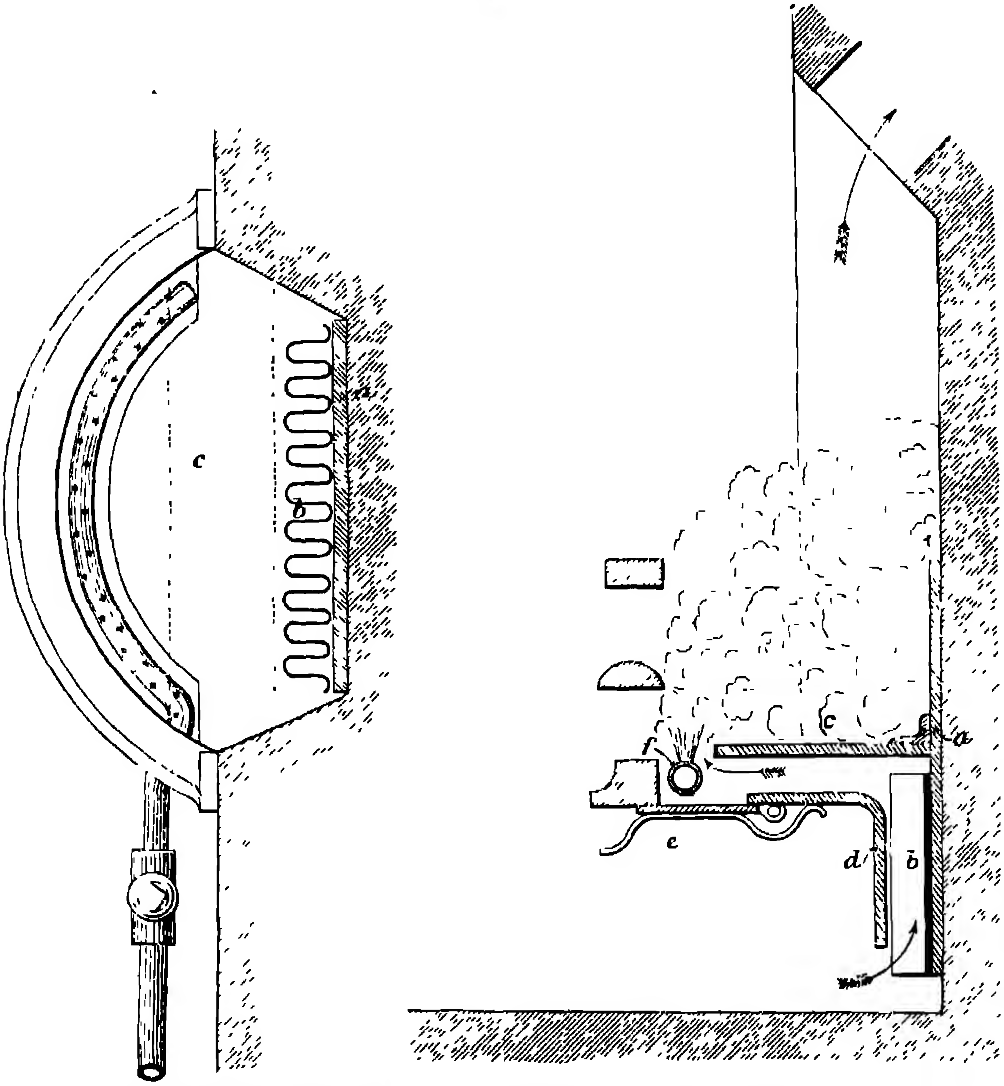
To accomplish this I have constructed a grate according to the annexed sketch. The iron dead plate *c* is riveted to a stout copper plate *a* facing the back of the fire-grate, and extending five inches both upwards and downwards from the point of junction The dead plate *c* stops short about an inch behind the bottom bar of the grate to make room for a half inch gas-pipe *f*, which is perforated with holes of about one-twentieth of an inch in diameter placed zig-zag at distances of three-quarters of an inch along its upper surface. This pipe rests upon a lower plate *d*, which is bent downwards towards the back so as to provide a vertical and horizontal channel of about one inch in breadth between the two plates A trap-door *e*, held up by a spring, is provided for the discharge of ashes falling into this channel. The vertical portion of this channel is occupied by a strip of sheet copper about four inches deep, bent in and out like a lady's frill and riveted to the copper back piece. Copper being an excellent conductor of heat, and this piece presenting (if not less than a quarter of an inch thick) a considerable sectional conductive area, transfers the heat from the back of the grate to the frill-work in the vertical channel An air current is set up by this heat, which, in passing along the horizontal channel, impinges on the line of gas flames and greatly increases their brilliancy So great is the heat imparted to the air by this simple arrangement that a piece of lead of about half a pound in weight introduced through the trap-door into this channel melted in five minutes, proving a temperature to exist exceeding 619° F or 326° C. The abstraction of heat from the back has moreover the advantage of retarding the combustion of the coke there while promoting it at the front of the grate.

The sketch represents a fireplace at my office, in a room of 7,200 cubic feet capacity facing the north. I always found it difficult during cold weather to keep this room at 60° F. with a coal fire, but it has been easily maintained at that temperature since the grate has been altered to the gas-coke grate just described.

This heating arrangement is not however essentially necessary; in several of the grates which I have altered for gas I have simply closed up the space below the bottom bar by means of a close-fitting ash-pan, and introduced the gaspipe behind the lower bar, an alteration which can be effected at very trifling expense, and presents the advantage of great cleanliness, the ash-pan being withdrawn only at intervals of several days for emptying. The appearance of the fire however is in that case much less brilliant than when the hot-air arrangement is added.

In order to test the question of economy I have passed the gas consumed in the grate through a Parkinson's 10-light dry gas-meter supplied to me by the Woolwich, Plumstead, and Charlton Consumer's Gas Company, the coke used is also carefully weighed.

The result of one day's campaign of nine hours is a consumption of 62 cubic feet of gas and 22 lb. of coke (the coke remaining in the grate being in each case put to the debit of the following day) Taking the gas at the average London price of 3*s* 6*d.* per 1000 cubic feet and the coke at 18*s.* a ton, the account stands thus for nine hours:—



a, Copper plate ¼ inch thick and 10 inches wide at back of grate, *b*, grill of copper ⅛ inch thick *c*, iron dead plate rivited to plate *a*, *d*, angle plate with trap-door *e* for removing ashes, *f*, gas-pipe about ½ inch diameter with holes ¾ inch apart

	d.
62 cubic feet of gas at 3*s*. 6*d*. per thousand	2 604
22 lb. coke at 18*s*. a ton . .	2 121
Total .	4 725

or at the rate of 0 524*d*. per hour In its former condition as a coal-grate the consumption exceeded generally two and a half large scuttles a day, weighing 19 lb each, or 47 lb. of coal, which at 23*s* a ton equals 5 7*d*. for nine hours, being 0 633*d* per hour. This result shows that the coke-gas fire, as here described, is not only a warmer but a cheaper fire than its predecessor, with the advantages in its favour that it is thoroughly smokeless, that it can be put off or on at any moment (which in most cases means considerable economy), that it is lit without the trouble of laying the fire, as it is called, and keeps alight without requiring to be stirred

It may appear strange at first that the use of the separated coke and gas to produce a given effect should be fully as cheap as using the raw material combining the two constituents, but the solution may be found in the

circumstance that in the case of the coke-gas fire no heat flashes up the chimney, but is utilised entirely for raising the coke in front of the grate to the condition most favourable to radiation into the room

I hold that it is almost barbarous to use raw coal for any purpose, and that the time will come when all our fuel will be separated into its two constituents before reaching our factories or our domestic hearths. Such a measure would not only furnish us with the complete solution of the smoke question, but would be of great value also as a money saving. In conclusion I may observe that I have taken up this question without the idea of profit, and shall be happy to furnish builders and others desirous to introduce the grate here described with the necessary indications to insure success C. WILLIAM SIEMENS

THE RUSSIAN IMPERIAL YACHT, "LIVADIA"

IN NATURE, vol xxii p. 270, we gave an account of this remarkable ship, and stated that we should report the results of her trials to our readers. We there said "it cannot be doubted that her speed will surpass 14 knots," and we pretty plainly intimated that it would, in our judgment, fall substantially short of 17 knots, in point of fact it has fallen between these limits, and nearer the higher than the lower, the average mean speed at the measured distance being 15 864 knots. The details of the several runs, which have not previously been published in London, we believe, are as follows .—

No. of Run	Indicated H P	Speed in Knots
1	12,267	15 69
2	11,704	15 53
3	12,387	15 83
4	12,437	15 65
5	12,857	15 92
6	12,472	15·65
Average	12,354	15·725

The trials of the *Livadia* were greatly hurried, the vessel going down the river on a Wednesday, making a preliminary run under steam on the following day, Thursday; on Friday she made a run at full speed for six hours, giving an average of 15 knots; and on Saturday she made her measured mile trials. Those who understand the conditions under which these steam trials were made will see at once that it was not possible to obtain the best results with a ship thus put under steam day after day, her boiler tubes getting doubtless more or less foul, and her machinery also falling somewhat out of perfect condition, especially where there were three separate sets of engines to be cared for The bottom was also foul from having been three months in the wet dock at Fairfield. The effect of haste in making the trials is visible in the variations of horse-power developed upon the runs, there being a difference of more than 1000 h p. between the power developed, for example, on the second run as compared with that of the fifth. The speeds given above show less discrepancies than the horse-powers, but it can hardly be doubted that the *Livadia* as she is can be driven at over 16 knots under fair conditions, without any alteration whatever. It is, as has been said elsewhere, highly probable that some improvements might be made in the screw propellers, as it is not to be expected that the best conditions were secured at the first attempt. In fact we have evidence that the central screw was set at a pitch different from that of the side-screws, and runs at a different speed, it now appears likely that the pitch should have been the same in all cases, and when the opportunity offers this change will probably be made, and the speed again taken Other slight modifications will doubtless also be tried, and those of our own naval architects, who have well considered all the facts, have formed the opinion that if all minor causes of interference with the best performance are removed, a speed approaching 17 knots may be reached in the *Livadia*. It needs no words of ours to convince the scientific world that whether any great increase of speed be obtained with this vessel or not, the Russian Government has rendered a vast service to naval science by demonstrating on a large scale and in a public and unquestionable manner, the fact that a vessel whose breadth is enormous, and whose length is but one and a half times her breadth, may with no very inordinate expenditure of power be made to take a high place among the few fastest ships of the world

But the interest in the *Livadia*, while it is greatest as regards her high-speed trials, by no means ends there Her steaming performances with diminished steam power are also very interesting In considering these the reader should remember that in this case as in all cases of fast ships going with reduced power and at reduced speed, the performances are subject to a double disadvantage first the *weight* of the machinery carried is of course in excess of what is needed to produce the reduced power, and secondly, the friction and other losses are likewise in corresponding excess. For example, when the *Livadia* is steaming say at 11 to 12 knots, she is employing less power than any one of her three sets of engines produces, and if she had not to go beyond such a speed she might dispense with the other two sets of engines and boilers, and thus be relieved of nearly 1000 tons of weight, and of two-thirds of the frictional and other losses which she is obliged to undergo when steaming at 11 or 12 knots with all her engines working at a reduced speed Bearing these facts in mind, we may now state that the reduced steaming of the *Livadia* is reported officially to have given the following results —

Aggregate Ind H P	Speed	Wind	Tide
2969	11 knots	With	Slightly
4770	13 ,,	,,	,,
8940	15 ,,	Against	Slightly against
10,037	15½ ,,	,,	Against

The indicated horse-powers above given were calculated from diagrams, and the speed was taken by log The results were reported, we know, in perfect good faith, and are a correct indication, in the main, of the relation between power and speed in the *Livadia* with her present screws, &c. They nevertheless appear to us to exhibit on the face of them some slight discrepancy, which is amply accounted for by the fact that the speeds were, as we have said, taken by the log, which does not admit of that minute accuracy which may and ought to characterise measured mile-trial results The above figures are borne out by the sea-passages of the yacht. She steamed continuously in fair and moderate weather at an average speed of somewhat more than 12 knots with an average expenditure of about 4000 Ind H.P.

With all the above facts and figures before us we see

clearly how vain have been the prejudices, and how baseless the predictions, which condemned ships of this type as incompatible with even moderately good speeds, and as ridiculous when the attainment of high speed was contemplated. It is with no small feelings of vanity, but with a genuine pride in a great scientific triumph which we ventured to predict beforehand, that we have witnessed the *Livadia's* success It is a success which England may well envy, and of which the Russian Government may well be proud Its bearing upon the future of steam navigation cannot fail to be considerable even in the mercantile marine, while it is quite impossible for the war navies of the world to escape its influence Our long-standing objections to the *Inflexible* and *Italia* types of ship are well known to our readers, the construction of such ships under the name of first-class ironclads being most trying even to the common sense, and much more to the scientific sense, of the country. With the *Livadia* in existence, and with the facilities which such great breadth as hers offers to the production of armoured ships worthy of the name, the exposure of our first-class ships to the destructive effects both of shells and of torpedoes, will not be endured We congratulate Admiral Popoff upon the established success of the great idea which he was the first to propound, and as the idea would still have remained a mere idea but for the powerful patronage of the Grand Duke Constantine, we gladly recognise again the scientific acumen and that "courage of his opinions" which distinguish His Imperial Highness By consenting to the trial of so great a naval experiment in a yacht of his own, the Emperor of Russia has secured a sea-palace of great speed, of unexampled accommodation, and of a freedom from rolling and pitching such as no other ship in the world enjoys

On the last-named points—those of pitching and rolling—we have to record very remarkable results We are informed on the best authority that in the gale in the Bay of Biscay, with waves running over twenty feet high, when ordinary vessels were seen rolling and pitching heavily, and even when the gale and the sea were at their highest, the greatest roll to leeward was 5 degrees, and that to windward 4 degrees, while the greatest pitch was 4 degrees and the greatest "'scend" 3 degrees This extreme limitation of motion was most extraordinary, excluding almost all the usual incidents of sea-life Nothing was secured on board, and nothing fell throughout the storm There were occasionally heavy blows of the sea under the flat shallow bow, and these caused much vibration at times, but nothing was disturbed, and even the paint is nowhere cracked throughout the wood-built cabins and palaces of the ship.

In the accident which the *Livadia* met with on her voyage from Brest to Ferrol, by striking heavily downwards upon some floating object or objects during a heavy gale in the Bay of Biscay, with a high and confused sea running, the value of water-tight subdivision has been strikingly demonstrated. The injuries done by the blows were extended by the heavy strokes of the sea under the bluff bow, and several of the forward compartments were filled A scientific friend who inspected the bow after the compartments were pumped out in the harbour of Ferrol, informs us that in two or three places the bulkhead divisions had evidently been badly struck and made leaky at the bottom, and in one compartment the sea was plainly visible through the broken plating. And yet nothing was known on board of these injuries when at sea beyond the fact (ascertained by "sounding") that a forward compartment of the double bottom had been somehow filled, so effectually was the ship proper preserved from all injury within the double bottom, and so little effect had the filling of the forward spaces upon the trim and behaviour of the ship! The *Livadia* is constructed of steel, and is as lightly built as our own fast steel ships of the latest date, and as a similar accident to the recent one might occur again, as it may to any ship of light draught and great buoyancy, it would no doubt be prudent to add something to the strength of the outer bottom where most exposed to strains and blows; but this is a matter of detail which we leave the naval architect to discuss. The great lesson to be derived from the incident is the immeasurable value of double bottoms and of great compartmental subdivision in sea-going structures. An ordinary large steam yacht not so subdivided might have been lost under like circumstances, and certainly would have been more or less jeopordised and more or less injured internally, in the present case not a particle of injury to the interior of the ship or to her costly fittings was sustained, and hours after the accident, with a very high and confused sea still running, the Lord High Admiral of Russia and his guests dined as safely, as easily, and almost as quietly as if he had been ashore in his summer palace of Orianda

A MEDICAL CATALOGUE

Index Catalogue of the Library of the Surgeon-General's Office, U.S. Army Vol i., A—Berlinski 4to, pp. 888 (Washington Government Printing Office)

THE saying of Hippocrates, that art is long and time is short, is so true, not merely of medical art, but of work in general, that most working men find their lives gliding so quickly away that they do not attempt great works, and very probably would not succeed if they did so But every now and then we come across men whose energy is so marvellous, and whose power of getting through work is so enormous, that we are struck with amazement at it Such a man is Dr. Billings, to whose extraordinary energy and perseverance we owe the present work. This purports to be only a catalogue of the Library of the Office of the Surgeon-General of the United States Army, and Dr. Billings takes care to call attention to the fact that it is not a complete medical bibliography, and that any one who relies upon it as such will commit a serious error. "It is," he says, "a catalogue of what is to be found in a single collection; a collection so large, and of such a character, that there are few subjects in medicine with regard to which something may not be found in it, but which is by no means complete." It is not, however, a mere catalogue in the ordinary sense of the word, inasmuch as its contents are not confined to the names and titles of books and their authors. It is also a catalogue of subjects, so that any one wishing to read up a particular subject will find under the appropriate heading a list of the chief works bearing upon it. Nor is this all. There are other catalogues in which a similar arrangement has not only been

attempted but successfully carried out. But this catalogue differs from all others inasmuch as it is the only compilation in which the herculean task of arranging in proper order the contents, not only of books, but of medical periodicals, has ever been essayed. To any person who is aware of the enormous extent of medical periodical literature, and who has had personal experience of the time and labour involved in looking up a few references, it seems almost incredible that any man should have had the courage to venture upon the task which Dr. Billings has successfully accomplished. To give the faintest idea of the work, we take a single heading—Amputation, and we find, besides a large number of works and references under this title itself, several other headings on the treatment of amputation, cases and statistics of amputation, double amputation, history of amputation, intra-uterine amputation, methods of amputation, multiple amputation, sequelæ and after treatment of amputation, spontaneous amputation, amputation in the course of disease, amputation in gunshot wounds, amputation in infants, amputation in joints, amputation in pregnancy, carpal and meta-carpal amputations, tarsal and meta-tarsal amputation, amputations at ankle-joint, amputations of arm, amputations of breast, amputations at elbow-joint, amputations of fingers and toes, amputations of foot, amputations of fore-arm, amputations of hip-joint, amputations of knee-joint, amputations of leg, amputations at shoulder-joint, amputations of thigh, amputations of toes, amputations at wrist-joint, besides cross references to Amputation considered under other heads, such as Gangrene, Hospitals, Surgery, Umbilical Cord, Arteries, Limbs, Osteomyelitis, Spinal Cord, Stumps, Frost-bite, Pregnancy, Pyæmia, Elbow-joint, Breast, Tibia, Ankle-joint, Astragalus, Aneurisms, Arm, Artery, Humerus, &c. On taking a single one of these headings, we find under it nineteen books, and on then attempting to count the references to periodical literature we go along until we come to the end of the letter C, and then stop in despair, for we have already got a hundred references, and find that to proceed to the end of the alphabet will be a work of both time and labour. The wearisomeness of counting the number of references in a small fraction of one sub-head may give the reader some notion of the labour involved in hunting out and writing down the materials, and yet, after all, such idea would be very imperfect, for the labours of Dr. Billings and his assistants have not consisted merely in giving these references. A much greater amount of time and trouble has probably been consumed in the consideration of what should be left out than by the labour of arranging and compiling what should be put in, for in indexing journals and transactions the general rule which they have followed has been that only original articles should be taken, though occasionally important papers in several periodicals, and reprints when the originals have not been in the library, have been indexed. In describing the arrangement of the book we cannot do better than quote Dr. Billings' own words:—

"This catalogue includes both authors and subjects—the names being arranged in dictionary order in a single alphabet. Under the subject-headings are included the titles of original articles in the medical journals and transactions contained in the Library, for which reason the Catalogue is commonly spoken of by those who are familiar with it as the 'Index-Catalogue,' and the name has been adopted as being brief and at the same time distinctive.

"The form adopted is essentially that shown in the 'Specimen Fasciculus' published in 1876, and it has been selected after a careful consideration of the criticisms and suggestions brought out by that fasciculus.

"The great majority of physicians, and especially of American physicians, who have given their opinion, have expressed a decided preference for this form; and although a librarian might find a complete separation of the catalogue of authors from that of subjects a little more convenient, the demand on the part of those who are to use it is very decidedly for the combination here given.

"The following points have been kept in view in the selection and arrangement of the subject-headings:—

"I. Those titles have been selected for subjects for which it is presumed that the majority of educated English-speaking physicians would look in an alphabetical arrangement.

"II. Where there is doubt as between two or more subject-headings, cross-references are given.

"III. Where both an English and a Latin or Greek word are in common use to designate the same subject, the English word is preferred, and references are given from the others.

"IV. As a rule, substantives rather than adjectives are selected for subject-headings. Exceptions occur to this in anatomical nomenclature, as 'Lachrymal duct', 'Thyroid gland'.

"V. In names of subjects derived from personal names, the latter precede, as 'Addison's disease', 'Eustachian tube'.

"VI. Local diseases or injuries are as a rule placed under the name of the organ or locality affected, as 'Kidney (*Abscess of*)'; 'Neck (*Wound of*)'. There are exceptions to this, in accordance with Rule I, *e.g.*, 'Abscess (*Perinephritic*).'

"VII. Cases in which one disease is complicated with or immediately followed by another are placed under the name of the first disease with the sub-heading '*Complications and Sequelæ*.'

"VIII. When the main subject of an article is the action of a given remedy in general, or its action in several diseases, it is indexed under the name of the remedy; but if it relate to its action in but one disease, it is indexed under the name of the disease.

"IX. The amount of sub-division made under the principal subject-heads depends very greatly upon the number of references to be classed.

"X. As a rule, the references are given from general to more special heads, but not the reverse. It is presumed, for instance, that those who wish to consult the literature on 'Aphasia' will turn to 'Brain (*Diseases of*)' and 'Nervous System (*Diseases of*),' as well as to 'Aphasia,' without being directed to do so by a cross-reference under the latter title.

"XI. Under the name of an organ will be found the books and papers relating to the anatomy and physiology of that organ. Following this usually come the abnormities and malformations of the organ, then its diseases, then its tumours, and lastly, its wounds and injuries.

"Anonymous works or papers are entered in regular order under the first word of the title not an article or preposition. Russian and Japanese titles are transliterated, and a translation is usually appended. Greek *names* are transliterated for the sake of uniformity in type.

"In indexing journals and transactions, the general rule has been that only original articles should be taken, but occasionally important papers are indexed in several periodicals, and sometimes a reprint is indexed when the original is not in the Library.

"The List of Abbreviations of Titles of Periodicals prefixed to this volume shows the journals and transactions which have been indexed to the present time. The right-hand column exhibits the volumes or numbers possessed by the Library, and, negatively, the deficiencies, which it is my earnest desire to fill. The List of Abbreviations is separately paged in order that it may be bound by itself, if desired, for use with succeeding volumes.

"Some of the abbreviations of names of places, especially in the United States, might have been still further shortened if the Catalogue had been intended for use only in this country But an analysis, by subjects, of so large a collection of medical periodicals is, necessarily, useful in St Petersburg, for example, as well as in Washington, its measure of utility in any locality being the extent of the collection of medical periodical literature therein. Intelligibility to foreigners, therefore, has been regarded as a quality essential to the abbreviations in question.

"In indicating pagination, the rule is that where the article does not exceed two pages in extent the first page only is given If it exceed two pages, both the first and last pages are noted.

"The work of preparing this Catalogue began in 1873, and has been carried on persistently, and as rapidly as the amount of clerical aid available and the nature of the work would permit.

"The present volume includes 9090 author-titles, representing 8031 volumes and 6398 pamphlets It also includes 9000 subject titles of separate books and pamphlets, and 34,604 titles of articles in periodicals"

The rapid progress of every branch of science, medical and otherwise, and the proportionate, or perhaps we ought almost to say disproportionate, increase of medical and scientific periodical literature, render it exceedingly difficult for the student to keep himself *au courant* with the newest discoveries The Royal Society's Catalogue of scientific papers conferred an inestimable boon upon scientific men, but it left much to be desired, inasmuch as it gave only the names of authors, and contained no index of subjects. Sometimes, too, its strict confinement to periodical literature is felt as an imperfection, for in cases where discoveries have been published in the form of pamphlets of a few pages, one searches through the Catalogue in the vain expectation of finding them However, we have hitherto had nothing at all resembling it in medical literature, but now we possess the first volume of a work which greatly excels it both in scope and size. Such defects as the volume possesses are due to the imperfections of the library of which it is a catalogue, and it is to be hoped that all those (and their name must be legion) who profit by the use of this remarkable production, will do their best to enable Dr Billings to make good the deficiencies.

It is clear that, however complete any catalogue may be at the time of its publication, the constant appearance of new books and pamphlets day by day and month by month must render it more and more defective. In order to supplement this catalogue, and prevent this gradually increasing deficiency from being felt as an evil, Dr. Billings and Dr. Fletcher are now publishing the *Index Medicus*, a monthly classified record of the current medical literature of the world. This is published by F. Leypoldt in New York, and by Trubner and Co in London. The great labour and expense involved in getting out this monthly index require for it a large circulation. At present, we believe, it is published at a loss, and an increased number of subscribers is urgently requested in order to permit its continuance. We therefore trust that every one who finds his time and labour saved by this Index-Catalogue will show his gratitude to Dr. Billings and those who have assisted him, not only by helping to supply the wants of the library at Washington, but by subscribing regularly to the *Index Medicus*.

We cannot conclude this brief notice without congratulating the United States Government on having in its service such men as Dr. Billings and his able assistants, Doctors Fletcher, Yarrow, and Chadwick, nor without expressing the thankfulness which every medical man owes to them for the great boon they have conferred on medicine in printing and issuing the present Index-Catalogue

THE PHILOSOPHY OF LANGUAGE

Max Muller and the Philosophy of Language By Ludwig Noiré (London Longmans, Green, and Co. 1879)

THE substance of this work has already appeared in the German periodical *Nord und Sud*, and the author here tells us that he has reproduced it in an enlarged form and in an English dress in order to do full justice to Max Muller's great merits in clearing the way "for future investigators" He considers that eminent services have been rendered to the cause of linguistic studies by the writings of the illustrious Oxford professor, and four out of the five chapters comprising this treatise are mainly occupied in putting this somewhat obvious fact in the clearest light. But he holds, in common probably with Max Muller himself, that the problem of the ultimate origin of articulate speech has not been solved in the brilliant and deservedly popular "Lectures on the Science of Language" Many difficulties are there removed, much light is thrown upon a great number of obscure points, several abstruse questions are treated with an amazing wealth of illustration, bringing them home to the meanest capacity, and sundry popular views, notably those stigmatised as the "Pooh-pooh" and "Bow-wow" theories, are either exploded, or reduced to their proper value. But the mystery of origin, the inexplicable ultimate residuum of roots, forming the constituent elements of all speech, remains almost unassailed, though distinct service has undoubtedly been done by narrowing down the question to this one issue. A still greater service is done when the gifted writer emphatically declares that these roots "are not, as is commonly maintained, merely scientific abstractions, but they were used originally as real words." This gave the death-blow to the Platonic "types," ideas, metaphysical entities and concepts which had still continued to obscure the subject, and block the way like so much mediæval rubbish. Herr Noiré aptly compares them to the *ova*, whence all animal and vegetable life. "By their development and uninterrupted growth all the known languages of the world have reached their marvellous structure, and become the body of reason and the instrument of mind" (p 55).

In the last chapter, which will doubtless be read with the greatest curiosity, the author takes up the subject where Max Muller had left it, and develops the theory on

the origin of language, which he had already broached in his "Ursprung der Sprache," specially devoted to that question. The essential peculiarity of the view here advocated is contained in the following passage —"Language is the CHILD OF WILL, of an active, not of a passive state; the roots of words contain the *proper activity of men*, and receive their significance from the *effects* of this activity in so far as it is phenomenal, *i e* visible. Human thought arises from a double root, the subjective activity, or the will, and the objective phenomenon which is accessible to the senses."

Language is further represented as "a product of *association* and of the community of feeling which is developed, intensified, and finally carried to perfection by community of life" (p. 81). Great stress is laid on the fact that human thought has a double root, the subject or individual activity, and its effect in the action, whence it follows that "the life of language stands in an indissoluble relation to the development of human action" (p. 83) The earliest meanings of verbal roots are all said to be "referred to human action," such notions as to dig, strike, scrape, scratch, tear, lying at the root of endless derived and secondary concepts.

Human thought is conceived as "an active process, a self-conscious, self-confident activity, not as a crude materialism imagines, the accidental play of unconscious atoms" (p 88) This active process is traced to common action, and language itself becomes "the voice of the community" (p 88). The essence of language consists in the naming of things, while the power of forming a notion of a thing, that is, of a group of phenomena grasped and conceived as one, constitutes the essential difference between man and the brute creation At the same time man can conceive of things only "because he has the gift of speech, because he can give them a name" (p. 90).

The power of giving names flowed from the power of using signs. "He used signs and thereby attained to the power of using names also; or, in other words, of betokening again by a sound what he had noted before" The transition from one process to the other, attributed to the active will, is stated to be "the most important part of the theory" (p. 92).

Then the power of giving signs to things grows out of the habit of modifying them for his own use. "Men dug caves, plaited twigs, stripped the beasts of their skin, the trees of their bark. Hence was developed the marvellous hitherto unexplained gift of abstraction, and this in the most natural way. Man learnt to conceive a thing as he learnt to create things. His own creations were the first *things* for him" (p 92). So that language conceives objects only "in so far as human action has touched, modified, reconstructed them; in a word, in so far as they have received *form*." Even such things as exist independently of the human will, or lie beyond the sphere of human action, are nevertheless brought within the sphere of human speech. "They become objects of human thought in the same way as the rest, that is to say, they are named as they would be, if the human hand had formed them" (p 98).

Such is the line of argument pursued in the attempt to build up a new theory of articulate speech, which is here conceived by an evident disciple of Schopenhauer and the Monistic school, as an emanation of the self-conscious human will, flowing from the power of forming abstract ideas, and dealing primarily and exclusively with such things only as are either the direct creation, or brought under the direct control and modifying influence of man. But this seems to be a complete perversion of the natural sequence of events in the evolution of man and all his faculties. Of these the very highest, next at all events to the moral sense, consequently the latest to be developed, was the conscious will. In the lowest savage tribes it is still often so feeble as scarcely to be distinguished from mere sensation and animal impulse Yet the speech even of the rudest tribes is almost invariably found to be of a very intricate mechanism, subject to definite laws of structure and harmony, possessed at times of a copious vocabulary, embracing a variety of objects entirely beyond the influence or control of man himself, objects whose names cannot by the most violent straining be traced to those of things created or modified by human action. It is very easy to quote a few instances in support of such a theory as this, especially from such highly imaginative languages as those of the Aryan family, in which analogy and metaphor have had such free play during a long period of comparative culture But hundreds of such examples would bring us no nearer than we were before to the starting point, to the faculty of naming things and actions, to the reason of certain sounds being selected in preference to others wherewith to name them.

The question still remains unanswered, whence came the "limited store of sounds with which man accompanied his action," and which are said to have in some mysterious way "associated themselves with the objects produced or modified by the action" The difficulty does not lie in the derivation of *cælum* or *hole* from a primitive root *sku* or *ku*, but in tracing the origin of this root itself, and, in general, of all roots, whether they have to do with human action or not. For it is not for a moment to be supposed that all the roots even of the Aryan family can be identified with the names of things subject to human influence. Such are, for instance, *as* expressive of mere existence, hence passive rather than active, *idh*, *indh*, to burn, whence αἴθω, αἰθήρ, *æstus*, *heat*, &c , words all applicable primarily rather to the powers of nature than of man, *ud*, *und*, to flow, whence ὕδος, *udum*, *unda*, Goth *wato*, *water*, &c , a purely natural object named directly from a purely natural conception, *svan*, to resound, whence *sonus*, *sound*, *svanitam*, *sonitus*, all words expressive of natural noise, and if Eichhoff is right in connecting the Gothic *sangws* and English *song* with this root, then these human actions can be conceived only as secondary derivatives from the primary idea of natural sound. This is the logical order of sequence, but it is as subversive of the author's theory as are many other Aryan roots which need not here be quoted. Enough has been said to show that this theory, while leaving the real question of origin untouched, will apply in any case to a part only of the original stock of roots in the Aryan family Nor, as stated, will it help us in the least towards an explanation even of these

On the whole it is to be feared that our author leaves the matter much where Max Muller left it at the end of his "Science of Language", for the theory here advocated assuredly does not answer the questions · How do mere cries become phonetic types? How can sensations be changed into concepts? These questions can be answered

only by divesting the mind of all metaphysical vagaries, and approaching the discussion in a spirit of strict loyalty to the established principles of evolution. The universe is not "a mental phenomenon," as Schopenhauer would call it, nor is speech the deliberate product of conscious will. It is an organism which, like all other organisms, had its origin in a germ, and its slow growth and silent development in suitable surroundings, independently of all conscious action. Yet in dealing with a subject of this sort one still feels how much easier it is to refute error than to establish truth. "*Utinam tam facile vera invenire possim quam falsa convincere*" A. H KEANE

OUR BOOK SHELF

Easy Lessons in Science. Edited by Prof. F. W Barrett I. *Easy Lessons in Heat* By C A. Martineau II *Easy Lessons in Light.* By Mrs. W. Awdry (London · Macmillan and Co, 1880.)

THESE excellent little lesson books deserve a wide circulation. Well and clearly written, they are at the same time strictly of the "scientific" rather than of the so-called "popular" style of exposition; there being none of the objectionable sensational element with which certain French works in light science have too greatly familiarised us The cuts with which the volumes before us are illustrated are numerous, appropriate, and many of them original In each case the reader is instructed in the simple apparatus needed to repeat the experiments described; so that a teacher who desires to give to young pupils a few elementary lessons in the sciences of heat and light will find here the very text-books most suited to his requirements. Miss C. A. Martineau's "Lessons in Heat" follows the usual order of text-books in that science. The first lesson deals with expansions, the second with notions of temperature, the third tells "how heat spreads," and so forth, and in the concluding chapters some of the fundamental facts of the relation between heat and mechanical work are made known One experiment which we do not remember meeting with before in the shape in which it is given deserves to be cited. It is a variation on Davy's old experiment with flame and gauze "Put a bit of camphor *on* the wire gauze, and hold a light *under* it. The vapour of the camphor passes freely through the gauze, catches fire, and burns with a blue flame till the whole of the camphor has been turned into vapour and burned But the flame does not pass through the gauze to set fire to the solid camphor"

Mrs. Awdry's "Lessons on Light" are no less felicitous in their treatment of the subject The usual popular text-book on Optics abounds in descriptions of different optical instruments, telescopes, microscopes, kaleidoscopes, and the like, without much trouble being expended upon first principles. But in these lessons first principles claim the prominent place: the first point explained is the law of inverse squares, and the second the geometrical laws of refraction and reflection—and the explanations are admirably yet quite simply done. A most interesting feature is that the latter half of these easy lessons is devoted to physical optics. One chapter on the wave-theory, and two entitled "Measurings" prepare the way for a capital lesson on Diffraction A lesson on the Spectrum and one on the Rainbow close the series.

We do not say that there is no room for criticism in judging these little volumes A professed teacher of Natural Philosophy might grumble at the omission of certain things that claim prominence in all the older text-books and in many of the syllabuses of contemporary examinations Yet we would challenge such critics to produce a more useful, or suggestive, or accurate set of lessons, or one more entirely free from the two besetting faults of sensational popularisation and educational cram.

It is to be hoped that Prof. Barrett will continue his labours in adding to the series he has so ably edited.

Outline of a Course of Natural Philosophy, with Specimen Examination Papers. By Gerald Molloy, D.D (London. Simpkin, Marshall, and Co, 1880.)

THIS work of 114 pages contains a syllabus-outline of the course of lectures in Natural Philosophy by Dr. Molloy, at the Catholic University of Ireland, and is reprinted chiefly to meet the wants of teachers in intermediate schools. To the syllabus, which is remarkably full and complete, is appended an extensive series of examination papers on all branches of physics except light, electricity, and magnetism, which are promised to follow These questions, though chiefly elementary, have been carefully prepared, and are a valuable part of the work. In an appendix Dr. Molloy reprints a paper giving an account of his particular form of bichromate battery, which appears to be peculiarly suited to the needs of schools and colleges, where a powerful battery of convenient form is required to be in readiness for occasional use

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications*]

[*The Editor urgently requests correspondents to keep their letters as short as possible The pressure on his space is so great that it is impossible otherwise to ensure the appearance even of communications containing interesting and novel facts.*]

Sir Wyville Thomson and Natural Selection

I AM sorry to find that Sir Wyville Thomson does not understand the principle of natural selection, as explained by Mr Wallace and myself. If he had done so, he could not have written the following sentence in the Introduction to the Voyage of the *Challenger* —"The character of the abyssal fauna refuses to give the least support to the theory which refers the evolution of species to extreme variation guided only by natural selection." This is a standard of criticism not uncommonly reached by theologians and metaphysicians, when they write on scientific subjects, but is something new as coming from a naturalist. Prof. Huxley demurs to it in the last number of NATURE, but he does not touch on the expression of *extreme variation*, nor on that of evolution being guided *only* by natural selection. Can Sir Wyville Thomson name any one who has said that the evolution of species depends only on natural selection? As far as concerns myself, I believe that no one has brought forward so many observations on the effects of the use and disuse of parts, as I have done in my "Variation of Animals and Plants under Domestication", and these observations were made for this special object. I have likewise there adduced a considerable body of facts, showing the direct action of external conditions on organisms; though no doubt since my books were published much has been learnt on this head If Sir Wyville Thomson were to visit the yard of a breeder, and saw all his cattle or sheep almost absolutely true, that is, closely similar, he would exclaim: "Sir, I see here no extreme variation; nor can I find any support to the belief that you have followed the principle of selection in the breeding of your animals." From what I formerly saw of breeders, I have no doubt that the man thus rebuked would have smiled and said not a word If he had afterwards told the story to other breeders, I greatly fear that they would have used emphatic but irreverent language about naturalists. CHARLES DARWIN

Down, Beckenham, Kent, November 5

Geological Changes of Level

In a most friendly notice in your last issue of the *Memoirs* forming the first volume of the official Report of the *Challenger* Expedition, Prof. Huxley takes exception to a sentence in my short Introduction. "There seems to be sufficient evidence that all changes of level since the close of the Palæozoic period are in direct relation to the present coast lines," and he asks in what possible sense this can be the case.

I fully admit the criticism, and that the sentence as it stands does not explain itself.

That it is not a relation of ordinary parallelism Lyell's and D'Orbigny's maps of old coast lines, a map published by myself in "The Depths of the Sea," and particularly the beautiful later maps of Jurassic, Cretaceous, and Tertiary France by M. Delesse, abundantly show. I have explained my idea of the relation in position between the recent deposits and those of the Tertiary and Secondary periods in "The Depths of the Sea" (pp 472-476) at some length I believe that the Jurassic, the Cretaceous, and the Tertiary formations are essentially *marginal* deposits, and that their belts of deposition form approximately a series of contour bands upon an elevation which has persisted throughout a long series of local and general oscillations, the sum of which has raised the whole through a small vertical range. Such oscillations have also, doubtless, affected the bottom of the sea, but nowhere to such an extent as to modify in any important degree the conditions of the abyssal region

Prof Huxley says, "There is nothing, so far as I am aware, in the biological or geological evidence at present accessible, to render untenable the hypothesis that an area of the mid-Atlantic or of the Pacific sea-bed as big as Europe should have been upheaved as high as Mont Blanc and have subsided again any time since the Palæozoic epoch, if there were any grounds for entertaining it." I think however he will admit that the following *Challenger* data, if they can be established, afford at least a presumption against an oscillation of such a kind, at all events in post-Triassic times, beyond which it is difficult to stretch even the imagination

The careful researches of my colleagues, Mr Murray and the Abbé Renard, with which I have had the advantage of being familiar during their progress, have led us to the belief that (1) the chalk of the Cretaceous period was not laid down in what we now consider deep water, and that its fauna, consisting mainly of shallow-water forms, merely touches the upper limit of the abyssal fauna, and (2) that no beds exist in the series of known sedimentary rocks which correspond in composition and in structure with the beds now in process of formation in the abyssal sea ("The Atlantic," vol. ii. p 299).

The hypothesis of the elevation of a mass of land equal to Europe and as high as Mont Blanc in the middle of one of the great ocean basins could in our present state of knowledge be defensible only on the supposition that it was a phenomenon of the same order as the elevation of some portion of our existing continental land, and there is now, to say the least, grave reason for doubting that any rock which is due to accumulations formed at depths over 2500 fathoms, the average depth of the basins to which Prof. Huxley refers, enters into the composition of any existing continent. The present land consists of a set of crystalline rock-axes of various ages, with a long succession of sedimentary deposits, all of which give evidence of having been laid down in water of moderate depth, piled up upon and against them. Such a hypothesis therefore, besides being without a single fact in its support, would be met by a strong adverse argument from analogy, and would be, so far, in a worse case than the hypothesis of the origin of species by natural selection.

I thoroughly agree, however, with my friend Prof. Huxley that "the value of the great work which is now being brought before the public does not lie in the speculations which may be based upon it, but in the mass and the solidity of the permanent additions which it makes to our knowledge of natural facts," and I imagine that all of us who are engaged in that work look upon it as our first and paramount duty to present these natural facts which have been acquired as simply and as effectively as we can. Still the generalisations or impressions, or whatever they may be, of the few men selected to observe these facts are as much a part of the result of the Expedition as anything else, and I think it is also our duty to offer them to our fellow-workers for what they are worth. C. Wyville Thomson

Bonsyde, Linlithgow, November 6

"The First Volume of the Publications of the 'Challenger'"—A Correction

There is a typographical error in my notice of the *Challenger* publications, published in last week's Nature, for which I should, of course, be disposed to blame the printer, had it not been hinted to me that my handwriting is sometimes not so clear as might be wished

I appear (p 2) to agree with the proposition that "the deep-sea fauna presents us with many forms which are the *dried* and but little modified descendants of Tertiary and Mesozoic species."

As few things can be much wetter than the inhabitants of the ocean abysses, this opinion seems to be, to say the least, eccentric.

But "dried" should have been printed "direct," which was the word denoted by my graphic symbols T. H. Huxley

Correspondence of Phenomena in Magnetic Storms

The Astronomer-Royal having lately received from the Observatory of Zi-ka-wei, in China (latitude 31° 12′ north, longitude, from Greenwich, 8h. 6m east), lithographed copies of the photographic traces of the declination and horizontal force magnets, extending from August 11 to 14, and from August 17 to 20 of the present year, has placed them in my hands for comparison with the Greenwich records Some particulars of this comparison are herewith annexed. Greenwich time is used throughout.

A general examination of the two sets of curves shows that the disturbances were usually greater in magnitude at Greenwich than at Zi ka wei. Comparing the curves in detail, it is found that on August 11, at 10 20[1] a m, after a quiet period, the declination and horizontal force magnets at Greenwich both made a sudden start, which was the commencement of a magnetic disturbance, lasting until midnight An apparently equally sudden start (from a quiescent state), in both declination and horizontal force, is shown on the Zi-ka wei curves, occurring in declination at 10 12 a m, and in horizontal force at 10.20 a.m. (as nearly as the small scale on which the curves are drawn will allow measures to be made) This first motion was to decrease the west declination and increase the horizontal force at both places A bold motion in the two Zi-ka-wei curves at 11 30 a m. (increase of declination, decrease of horizontal force) has corresponding decrease of horizontal force at Greenwich, not accompanied, however, by much motion in declination. And of numerous fluctuations occurring at Greenwich between noon and midnight of the same day, some appear to correspond with motions at Zi ka wei, whilst others do not.

A calm state follows at both places, until near noon of August 12. On this day at about 11 40 a m the magnets at Greenwich made a further start, and until 4 p.m the movements were large. A corresponding start is also shown in both the Zi ka wei curves (commencing, according to the register, some minutes sooner than at Greenwich), the movements following being similarly large. Afterwards, until 6 a m. of August 13, considerable oscillation was nearly continually shown at Greenwich, there being especially a large change of declination between 7 and 9 p.m (August 12), but there is no strongly marked motion at the latter time at Zi-ka-wei, and the changes are throughout much smaller than at Greenwich Later on August 13 further oscillations occur at both places, but the separate motions are in no particular accordance. The period of disturbance seems definitely to come to an end at both places at 6 a.m on August 14.

A period of quiet is broken at Greenwich on August 18, at 1 45 p.m, by a sharp though small movement both in declination and horizontal force (increase of both). There is a corresponding sharp increase (after quietude) of horizontal force at Zi ka-wei, but no change of declination. A bold increase of declination and decrease of horizontal force at Greenwich at 7 a m. of August 19 is accompanied by a similar decrease of horizontal force at Zi-ka wei, but with little change of declination. Bolder changes occur at the latter place at noon, but with comparatively small change at Greenwich. The magnets become quiet at both places at or near midnight of August 19.

The general result of this comparison of Greenwich and Zi-ka-wei curves appears to be that, after a quiet period, the first indication of disturbance, if sudden (it need not be large) occurs simultaneously or nearly so at both places, but that during the

[1] Approximately stated to be 10 30 in my previous letter (Nature, vol xxii p 361) and so quoted by Mr. Whipple (p 558). The time above given is more exact

continuance of disturbance the oscillations of the magnets seem to be so locally modified that it becomes difficult to trace correspondence: some movements appear to correspond, and some not. A strongly-marked bend in the trace at one place may appear, as it were, stunted in that at the other place, or may not be perceptible at all The disturbances appear to die out at pretty much the same time at both places. All this confirms very much what Mr. Whipple has already pointed out as regards Melbourne (NATURE, vol. xxii. p. 558).

M. Dechevrens, in some remarks which accompany the sheet of curves, notes that the disturbance of August 11-14 is the greatest experienced since the establishment of photographic registration at Zi-ka-wei in the year 1877, and he considers that the changes then observed (those of vertical force included, of which he gives no curves) are similar to such as would be produced by a powerful magnet placed in a certain defined position It may perhaps be here pointed out that the results given by the Astronomer Royal in his paper, "First Analysis of One Hundred and Seventy-seven Magnetic Storms" (*Phil. Trans.* for 1863) appear to give no support to a theory of this kind, and indeed seem conclusively to show that at Greenwich the observed disturbances cannot be accounted for in any such way.

It should be added that M. Dechevrens reports also that strong earth currents were experienced on August 11 and 12 on the submarine telegraph lines connecting Shanghai with Nagasaki and with Hong Kong, as well as on the land lines in Japan, so much so that correspondence was frequently interrupted, but that no interruption appears to have been experienced on the occasion of the generally smaller magnetic disturbance of August 18 WILLIAM ELLIS

Royal Observatory, Greenwich, November 6

Meteor

A VERY large and brilliant meteor was observed here at 6h 41m. p.m G M.T., on November 8 Its size was at least equal to one fourth of that of the full moon, and it lit up the whole garden for about a second and a half. It was pear-shaped. The colour was white, and left behind it a pale red train. Its path was from a point half-way between α and δ Persei to 3° above ν Ursæ Majoris. The sky was rather hazy at the time.

Stonyhurst Observatory, November 9 S. J PERRY

Condition of Jupiter

ON the evening of the 2nd I had a fine view of Jupiter with my 6-inch Cook's equatorial The general appearance of the planet was remarkable for the bright colouring of the belts and of the red spot, a circumstance strongly noted by a gentleman who was observing with me, and who had not seen the planet for some time

I could not however trace the usual white ring round the red spot. Below the red equatorial belt was a row of four or five small irregularly-shaped spots, nearly black in tint, and resembling sun-spots, seen under a low power.

These dark spots seem now affecting Jupiter's surface in several parts, and are certainly not usual to it About 9h. 26m. Satellite I. was occulted. I watched it gradually coming to contact, and at last it seemed to advance on the face of the planet, at least one-half of its diameter appearing to project thereon. It then faded out gradually

September 3, 1879, at 9h 8m, with the same instrument Satellite III. reappearing after occultation, was slightly (but certainly) projected on to the disk of the planet It will be interesting to notice whether the present condition of Jupiter will be accompanied by more than ordinary displays of auroræ, of which symptoms have already appeared.

Guildown, November 6 J. RAND CAPRON

P.S —Since writing the above accounts reach me of auroræ at Brighton on the 3rd and in the Orkneys on the 4th instant.

Vox Angelica

MANY of your readers may be acquainted with the nature of the Vox Angelica stop on a good organ. It consists of two ranks of pipes of small scale and delicate quality of tone, one of which is tuned slightly sharp, so that a wavy (hence called *Unda Maris*) sound is produced. Now it is possible to obtain very similar effects on an ordinary Estey American organ. Given the viola and violetta stops to be drawn out, wrap a band of india-rubber (an ordinary elastic band does very well) round the neck of the viola stop so that it cannot return completely home, on moderate pressure, and allowing a fraction of an inch to intervene between its true final position when inactive; beats will be heard of intensity depending upon the deviation from complete occlusion of this stop. The nearer the viola stop is to occlusion the more rapid the beats, but it is undesirable to obtain rapidity, as the lower notes are too prominently out of tune in this case. Anybody can, by experiment, determine the proper amount of deviation to be employed, and having done this the effect is remarkably good. On an Estey, the two stops mentioned are the only admissible ones for such an experiment, from consideration of overtones. No doubt some of your readers may adopt a more elaborate and convenient method of regulating the deviation than by elastic bands, after some experiments. It may seem a paradox to obtain beautiful concordant effects by the use of discordant vibrational relations, but it is undeniable that on a first class organ the Voix Celeste, or Vox Angelica, or Unda Maris, is a most beautiful stop, and is capable of producing perfect *con sordini* effects. GEORGE RAYLEIGH VICARS

Woodville House, Rugby, November 3

Solids and Liquids at High Temperatures

SOME years ago I made an investigation much simpler but somewhat similar to that referred to by Prof Carnelley in NATURE, vol. xxii p 435 An account of the experiments then made was communicated to the Royal Scottish Society of Arts, 1874-75. One of the results of that investigation was that while we do know something about the temperatures at which different forms of matter change from one state to another when a "*free surface*" is present, yet we are utterly ignorant of the temperature at which that change will take place when no "*free surface*" is present. It will be necessary here to explain that a "*free surface*" is any surface of the body under examination at which it is *free* to change its state. A surface of water, for instance, in contact with its own vapour is a "*free surface*" for the water passing into the gaseous state. The surface of a piece of ice in water, again, is a "*free surface*" at which the water may freeze or the ice may melt. And what are known as the freezing, melting, and boiling points of water are the temperatures at which these changes take place when such "*free surfaces*" are present. As to what the freezing, melting, and boiling points are when these "*free surfaces*" are absent, we have at present no knowledge whatever. All we know is that the freezing point is lower, and the "melting" and "boiling points" are higher, than when "*free surfaces*" are present.

The first of these points is too well known to be referred to here. The last point was illustrated in the paper referred to by an experiment in which water was heated in a metal vessel under atmospheric pressure to a temperature far above the "boiling point," when the water exploded and violently ejected itself from the vessel The superheating of the water was accomplished by carefully excluding all "*free surfaces*" by bringing the water into as perfect contact with the metal of the vessel as possible

Many experiments were also made to get direct and thermometric experimental illustration of the existence of ice at a temperature above the "melting point," but no satisfactory illustrations were got, on account of the great difficulty of getting quit of "*free surfaces*" Of course so long as there existed a "*free surface*" at the surface of contact of the ice with the thermometer, the temperature at that part could not rise above the "melting point." It was however shown by indirect evidence that ice may exist at a temperature above the "freezing point" by referring to the well-known and beautiful experiment of passing a beam of light through a block of ice. When this is done with the aid of proper apparatus it is seen that the heat of the ray is absorbed by the ice, and that melting takes place at different points inside the block. Now the presumption is that the heat is absorbed at all points inside the block, but as the melting only takes place at certain points the heat absorbed where there is no melting must raise the temperature of the ice at those points above the "melting point," and the heat there absorbed by the ice will be conducted to the "*free surfaces*," where it is spent in melting the ice

Now though I was perfectly prepared to find that Prof. Carnelley had succeeded in heating the *inside* of a block of ice to a temperature above the "melting-point," I certainly did not expect so high a temperature as his experiments indicate to be

possible. But what is still more puzzling is how Prof. Carnelley succeeded in burning his fingers with the ice. Our previous knowledge would lead us to suppose that the outside surface of the block of ice was a *free surface*, and that therefore it would be impossible, however high the temperature of the inside of the block, to heat the outside above the "melting point," as we should expect the ice to melt or to sublime at the outside, and keep the temperature at 0° C.

These expectations being disappointed, we naturally look to the decreased pressure under which Prof Carnelley's experiments were made for an explanation of this most unexpected state of matters Now it is very evident that when dealing with pressures of about one atmosphere, and with temperatures of 120° and 180° C, that pressure, as pressure, has nothing whatever directly to do with the "melting point" of the ice While this is the case, it is equally evident that it has a most important influence on the surroundings of the ice. At the pressure of 4 6 mm., at which the experiments were made, no water would be present, there would be nothing but ice and water-vapour. Here then appears to be the great teaching of Prof Carnelley's experiments *They show that the surface of ice bounded by its own vapour is not a "free surface"* This result is so very unexpected that much consideration will be necessary before we can re arrange our ideas to meet the new facts

We might imagine that nothing could be more free than the surface of a body bounded by nothing but its own vapour, yet Prof Carnelley's experiments seem to say it really is not so, and not being a "*free surface*," we of course know nothing whatever of how high the temperature will require to be before the ice will melt under these conditions

These experiments of Prof. Carnelley's are so interesting that we wait with impatience a full description of them His results indicate something new with regard to the influence of a liquid on its melting solid I observe that Prof. Carnelley's results are doubted by most of your correspondents, but for the present we must accept them when Prof Carnelley distinctly states that the temperature of the ice was taken by means of a thermometer in contact with the ice JOHN AITKEN

Darroch, Falkirk, N B., October 30

Wire Torsion

IN the letter in NATURE, vol xxii p 604, which we wrote at the request of Major Herschel, who asked for information regarding the connection between tensional and torsional strains of a brass wire, we mentioned that there were many papers scattered through the *Proceedings* of learned societies dealing with the fluidity of metals There is one communication to which we might specially have referred, as it deals in particular with the torsional yielding of wires under tension, and this is a paper on "Torsion," by Prof G Wiedemann, in the *Annalen der Physik und Chemie*, No 4, vol vi, 1879, pp 485-520, and of which a translation is given in the *Philosophical Magazine*, vol. ix, January 1880, pp 1-15, and February, pp 97-109 The first part of this paper gives a detailed account of experiments which show:—(1) That a brass wire often subjected to a particular torsion, either in one or in both directions, becomes "killed" for any less torsions, that is, follows Hooke's law for its temporary torsions, (2) that a wire under tension acquires greater torsional set from a given torsional couple than when the wire is unextended, (3) that a wire under even considerable tension may be killed by torsion in alternately opposite directions, that is, it will obey Hooke's law for any tension or torsion less than the stresses actually applied originally. Prof Wiedemann in the second part of his paper considers the well-known "agitation effects," and enters on an explanation of the phenomenon based upon molecular allineations referring to the magnetisation theory of Weber and Kohlrausch which is based on the same idea

The strains in Prof Wiedemann's wires were however much less than in those used in Major Herschel's experiments.

London, November 8

Heat of Formation of a Compound

IN NATURE, vol. xxii p. 608, there is a paper on "Recent Chemical Research," in which under the head of work by Thomsen the following law is enunciated:—

"The heat of formation of a compound substance is the difference between the sum of the heats of combustion of the constituent elements of the compound and the heat of combustion of the compound itself." After that it is shown that this is not the true heat of formation of the compound, as many important corrections have to be made On referring to Berthelot's "Essai de Mécanique Chimique" I find the following:—"The heat of formation of an organic compound from its elements is the difference between the sum of the heats of total combustion of its elements and the heat of combustion of the compound with formation of identical products"

Can any of your readers inform me whether Thomsen or Berthelot first enunciated this law?

Another point is, that Berthelot apparently makes no reference to the corrections for the heat absorbed in dissociating the molecules of the elements, &c A P. LAURIE

Edinburgh, November 1

The Yang-tse, the Yellow River, and the Pei-ho

IN replying to the letter of your correspondent (NATURE, vol. xxii p 559) on the subject of my recent paper on these three rivers, I have to thank him for his very probable explanation of the excessive estimate made by Sir George Staunton of the amount of sediment discharged by the Yellow River.

The estimate given in my paper of the water discharge of the River Plate is *ipso facto* an assumption made by Mr. George Higgin from Mr. Bateman's calculation of the minimum flow of that river, which he found to be 670,000 cubic feet per second. It might have been better, however, if I had added Mr Higgin's qualifying remark that such an estimate of the mean volume of water was "very much under the mark" (NATURE, vol xix. p. 555)

The anomaly of the surface current varying in velocity with the same average depth of water has not been unnoticed by myself, though I am unable to give a satisfactory explanation of the difficulty H. B. GUPPY

Woodlane, Falmouth, November 6

The Thresher

WHAT is the "thresher"? It is generally assumed to be the fox-shark (*Alopias vulpes*), but in a recent number of *Land and Water*—which I have only just seen—Mr Frank Buckland says that he believes it to be "the gladiator dolphin or sword grampus" (*Orca gladiator*). This he infers from a drawing of Lord A Campbell's, of which he gives a copy. The tail, he says, is not that of the fox shark But as it is heterocercal it cannot be that of a grampus or any other Cetacean Whatever it is I suppose that there is no doubt that it throws itself out of the water ("high as the masthead" [of a trawler] one of Mr. Buckland's correspondents avers) Does it do so more than once? Once, many years ago, between Sydney and New Zealand, I saw, what they said was a fight between a thresher and a whale, but there was nothing to be seen beyond a splashing of the water Last year off Lisbon I witnessed a similar event Does the sword fish also attack the whale? Lord A. Campbell, in the letter accompanying his drawing, estimated the length of his thresher at "upwards of thirty feet," this is twice the length given by Yarrell FRANCIS P PASCOE

October 30

Since the above was written I see that Dr Gunther, in his new work on Fishes, says: "Statements that it (the fox shark) has been seen to attack whales and other large cetaceans rest upon erroneous observations' (p 322)

"STUDENT" should refer to Newcomb's "Popular Astronomy" with respect to the larger telescopes. For results he must refer to the publications of the Royal and Astronomical Societies, the Washington Observatory, &c.

PAUL LAFARGUE.—We regret we have no further details on the labours of the U S. Fish Commission in increasing the food supply of the country

ILLUSTRATIONS OF NEW OR RARE ANIMALS IN THE ZOOLOGICAL SOCIETY'S LIVING COLLECTION

I

THE sagacious founders of the Zoological Society of London made it a special rule that no dividends or gifts of any kind should be distributed amongst the

members. On the contrary, every Fellow has to contribute an annual sum towards the maintenance of the Society's establishment, unless he prefers to pay a life-composition in lieu thereof. Moreover, the Society are so fortunate

FIG 1 —The Musk deer (*Moschus moschiferus*) (From a drawing by Mr J Wolf from nature)

as to be unencumbered by borrowed capital They have consequently no burden in the shape of interest to be provided for It follows that after putting aside

FIG 2 —The Japanese Wolf (*Canis hodophylax*).

from their income a sum sufficient to meet the annual expenditure, they are able to devote the surplus to new buildings in the Gardens, and to the acquisition of new and rare subjects for the menagerie. While the supply of lions, tigers, elephants, and other well-known animals must always be kept up for the delectation of the ordinary public, and for the maintenance of the best possible living series of animals, it is also thus in their power to acquire animals of specially scientific value, in which the casual observer would take little interest, and which would, therefore, be quite ineligible except in a scientific point of view This course of action has been adopted for many years, more especially since the foundation of the office of "Prosector" to the Society. For these special acquisitions not only delight the eyes of the intellectual observer while they live, but furnish the prosector with subjects for his studies when dead. Those who are acquainted with the *Proceedings* and *Transactions* of the Zoological Society of London will be well aware of the amount of work that has thus been accomplished as regards the anatomy of many of the rarer birds and mammals.

It is, however, by no means by purchase only that rare animals are added to the Zoological Society's collection. Numerous friends and correspondents in almost every corner of the earth are in constant communication with the Secretary of the Society, and are ever endeavouring to obtain specimens that may be acceptable to the collection. In fact the donations have of late years become so numerous that they have not unfrequently rivalled in number and interest the objects acquired by purchase Taking the acquisitions from these two sources together, there are always a considerable number of objects in the Society's collection that specially invite the attention of the observant naturalist. Amongst these rarities there are at the present moment the following, of which illustrations are given, drawn upon wood by Mr J Smit, an artist constantly employed by the Zoological Society.

1. The musk-deer (*Moschus moschiferus*) was well known to the older writers on zoology as the animal that has from long periods of time supplied the "musk" of commerce This scent is still much in vogue in the East, but in Western Europe has been long superseded by more refined perfumes, though it may be remarked that one of the fashionable dealers in Bond Street still keeps a stuffed musk-deer in his window, and is doubtless ready to supply the product in question.

The musk-deer was until recently usually associated with another group of mammals to which it has really very little affinity Dr Gray and other systematists united it with the Chevrotains (*Tragulus*) of India and tropical Africa —a group of ruminants remarkable for their small size and hornless heads, and presenting somewhat of the appearance of diminutive antelopes. M. Alphonse Milne-Edwards of Paris was, we believe, the first naturalist to show that this allocation was unnatural. In his excellent essay on the Chevrotains, published in 1864, M. Milne-Edwards proved conclusively that these little-understood animals constitute a peculiar family of ungulates quite distinct from either the Bovidæ or Cervidæ, and in fact in some respects approaching more nearly to the pigs (Suidæ). The correctness of these observations has been since fully demonstrated by Prof. Flower, Mr. Garrod, and other systematists.

The musk-deer therefore remains unique in its own group, and constitutes a special division of the Cervidæ

INTERNATIONAL MONTHLY CHART

Showing mean pressure, mean temperature, mean force and prevailing direction of winds at 7 35 A. M., Washington mean time, for the month of December, 1878, based on the daily charts of the International Bulletin

but long may we wait, it is to be hoped, before this event shall happen.

Of the curious nesting habits of *Scopus* we have excellent accounts from Brehm, Heuglin, and other naturalists who have visited the Upper Nile. But one of our own countrymen, a not less active or experienced observer—has likewise written a most interesting account of this bird's economy, and we cannot do better than transcribe a part of it

"The *Hammerkop* (literally hammerhead)," says Mr Layard in "The Birds of South Africa," "is found throughout the Colony and all the way to the Zambezi, frequenting ponds, marshes, rivers, and lakes. It is a strange, weird bird, flitting about with great activity in the dusk of the evening, and preying upon frogs, small fishes, &c At times, when two or three are feeding in the same small pool, they will execute a singular dance, skipping round one another, opening and closing their wings, and performing strange antics.

"They breed on trees and on rocky ledges, forming a huge structure of sticks, some of them of considerable thickness. These nests are so solid that they will bear the weight of a large, heavy man on the domed roof without collapsing The entrance is a small hole, generally placed in the most inaccessible side. The eggs, three to five in number, are of a pure white, axis 1" 9"', diam 1" 4"'

"On my late friend Jackson's farm, at Nel's Poort, there is a singular rocky glen between two hills In this spot a beautiful permanent spring called 'Jackalsfontein' takes its rise Of course, in consequence, there are a few wild almond and other trees, and the place is a little oasis amid the barren mountains. It is a favourite resort of wild animals, hyænas, leopards, jackals, &c., and here Mr. Jackson has constructed one of his most successful hyæna-traps On the ledges of the rocks in this secluded spot a colony of Hammerkops have built for years. Some of the nests are quite inaccessible, while others can be reached with a little trouble I counted six or eight within fifty yards, and some of them contained at least a large cartload of sticks Mr Jackson told me they occupied the same nest year after year, and added to it or repaired it as required. About some that I visited I found brass and bone buttons, bits of crockery, bleached bones, &c. Mr. Jackson said if a 'Tottie' lost his knife or tinder-box on the farm, or within some miles of the place, he made a point of examining the hammerkops' nests, and frequently with success, the birds, like the 'Bowerbird' of Australia, embellishing their dwellings with any glittering or bright coloured thing they can pick up."

A SUCCESSFUL AFRICAN EXPEDITION

AFRICA is overrun with explorers of all nationalities Too often of late have we had to read of failures, of abortive attempts on the part of expensively-equipped expeditions to reach the field of their work, or of deaths by fever or assassination after the first difficulties were overcome. In spite of all, however, the unprecedented activity of recent years in this favourite field of exploration has pretty well filled up, with the leading features at least, that great blank space in the heart of the continent which in the rude maps of our schoolboy days was marked "unexplored." In the very centre of that space there is still however a blank, giving ample scope for work for the numerous Belgian expeditions that have hitherto done so little. It was to fill up this blank to some extent that the Geographical Society, about two years ago, obtained subscriptions to send out an expedition under young Keith Johnston, who had inherited an enthusiasm for geographical work quite worthy of the name he bore As his subordinate and as geologist to the expedition, the Society appointed another young Scotchman, Mr Joseph Thomson, a pupil of Prof. Geikie, who recommended him to the Geographical Society. To him, we grieve to say, it has been left to tell the story of the expedition, which he did, and did well, on Monday night at the opening meeting of the Geographical Society. This expedition is remarkable in many respects, in some points more remarkable than any other African expedition that we know of The outline of its story is soon told. With 150 of the best men that could be found in and around Zanzibar Keith Johnston left that place in May, 1879, and striking at once to the south-west, made for the north end of Lake Nyassa, which was the real starting-point for fresh work. Little more than a month after the start, young Johnston, who seemed to have the nerve and stamina of an athlete, succumbed to the malarious influences of the coast region, and was buried by his companion at Behobeho, to the north of the Lufiji river. Mr. Thomson, inexperienced youth of twenty-two though he was, was equal to the emergency With admirable tact and nerve he took his place as the sole leader of the expedition, and accomplished even more than the work which the Society had chalked out for it. By an unexplored route, through barren wastes and over lofty mountains, through the sneaking Wakhutu and the warlike Mahenge, he and his followers made their way till their eyes were gladdened and their weary spirits refreshed by the sight of the waters of Nyassa Thence, after brief rest, they resumed their march over the lofty and undulating plateau, which they found occupied the region between the north end of Nyassa and the south shore of Tanganyika Leaving here the bulk of his followers, Mr Thomson, with a handful of men, trudged his way over the rugged western shores of Lake Tanganyika, to visit the Lukuga and settle the question whether it was an outlet or an affluent of the lake, a question, which, one would think, could be easily solved, but on which Stanley and Cameron published diametrically opposite statements After visiting the missionary station near the mouth of the river, and running across to Ujiji, Mr Thomson returned to the Lukuga and traced it for some miles of its downward course. After barely escaping from the murderous Warua with their lives, the party sailed down the lake, and rejoining their companions made the return journey to Zanzibar along the usual caravan route with unprecedented rapidity, in about a year after the expedition set out under their late chief Mr. Thomson declared with just pride that all this was accomplished without the shedding of a drop of blood for either offensive or defensive purposes, with one exception he brought all his men back "in the best of health and condition"; he has collected certain information about a considerable region which no white man had previously visited, he has solved one of the few remaining great problems of African geography; and he has located with certainty a great salt lake (Hikwa) whose existence previously had only been based on native rumour Mr. Thomson is a trained geologist, and as such he has doubtless seen more than almost any previous explorer. He tells us of the metamorphic schists and gneiss which compose the mountains of the great central plateau; of the many extinct volcanic cones that lie around the north-west end of Lake Nyassa, and of the metamorphic clay slates, felspathic rocks and volcanic porphyries and tuffs that look down on the lake from the north and north-east. His further geological insight may dispel some of the illusions that seem to be abroad as to the abounding wealth of the African Interior. Much of the country between the coast and Nyassa is barren waste; and the chief characteristic of the region between Nyassa and Tanganyika he found to be "utter barrenness and the absence of anything worth trading for" Instead of the mountains of iron and the miles of surface coal, nowhere did he see a single metal in a form which a white man would for a moment look at as a profitable or workable speculation; there is very little more iron, he

maintains, than is sufficient to supply the simple wants of the natives. Coal he saw none, and he does not believe that such a thing exists over the wide area embraced in his route. This may be discouraging, but it is wholesome, and may prove a check to the wild schemes sometimes broached by speculators for opening up the African interior. From the Chimboya Mountains to the southeast of Tanganyika Mr. Thomson found numerous streamlets flowing southwards, doubtless to join the Chambeze, which, after passing through many a lake and levying tribute from a region one million square miles in extent, pours its almost Amazonian volume, as the Congo, 3000 miles below, into the bosom of the broad Atlantic The much-debated Lukuga he found, as Mr Hore had found shortly before him, to be a broad and rapid river, flowing westwards from the Tanganyika Lake to the Lualaba, as the Congo here is called; and Lake Hikwa he saw was a fine sheet of water with no outlet, lying among the lofty mountains, which stretch away east from Southern Tanganyika What may be the extent and value of the purely geographical observations obtained by Mr Thomson we have no means of knowing, doubtless in this respect the expedition suffered in the death of Mr Johnston, who was a trained geographer But in other respects, in information as to the structure of the country, the nature of its products, and the character of its varied peoples, the expedition under Mr. Thomson has been fruitful to a high degree, altogether it is one of the best pieces of original work which our not too energetic Geographical Society has ever done. Mr. Thomson's well-written and well-read paper was received with enthusiasm by an unusually distinguished audience We trust to be able very shortly to give details concerning both the geography and geology of the Central Plateau from Mr Thomson's own hands

UNITED STATES WEATHER MAPS, DECEMBER, 1878

IMPORTANT changes took place this month in the distribution of the earth's atmosphere as compared with what obtained during the previous month, and these were accompanied with at least equally important changes in the geographical distribution of the temperature.

If a line be drawn from Texas to Newfoundland across the Atlantic, the north of France and Germany, thence curving round to south-eastward through the Black Sea, the Caucasus, India, the East India Islands, and Australia to the south island of New Zealand, it is found to pass through a broad and extended region where atmospheric pressure was throughout considerably below the average of December, and this low pressure was still further deepened at various points along the line. Again, another line passing from Australia through the Philippine Islands, Japan, Mantchooria, Behring's Straits, and Alaska, also marks out an extensive region where pressure was uninterruptedly below the mean

On the other hand atmospheric pressure was above the average, and generally largely so, over the United States to west of long. 90°, over Greenland, Iceland, Faro, Shetland, and over a large portion of the Old Continent bounded by a line drawn from Lapland round by Lake Balkhash, Canton, Pekin, to at least the upper waters of the Lena. Another area of high pressure extended from Syria, through Egypt and East Africa to the Cape, and part of a third area of high pressure appeared in the north island of New Zealand

As regards North America, the greatest excess of pressure, 0·196 inch above the average, occurred in the Columbia Valley, from which it gradually fell on, proceeding eastward to a defect from the average of 0·146 inch about Lake Champlain and to northward, rising again to near the average on the north of Nova Scotia. To the north-east and north of this region exceedingly high pressures for these regions and the season prevailed, being 0·635 inch above the average in the north-west of Iceland, 0·500 inch in the south of Greenland, and at the three stations in West Greenland, proceeding northwards, 0 445, 0 402, and 0 346 inch

West Greenland being thus on the west side of the region of high pressure which occupied the northern part of the Atlantic, and on the north-east side of the area of low pressure in the States and Canada, strong southerly winds set in over the country, and the temperature rose at the four Greenland stations proceeding from south to north to 1° 1, 8° 8, 12° 1, and 14° 4, above the averages As the centre of lowest pressure was in the valley of the St. Lawrence about Montreal, strong northerly and westerly winds predominated to southward and westward, and there consequently the temperature was below the average, the deficiency at Chicago and St Louis being 9° 5; and winds being easterly and northerly in California, temperature there was also under the average. On the other hand, in the New England States, the greater part of the Dominion of Canada, a considerable portion of British America, and in West Greenland, as already stated, temperature was above the average Pressure was much higher at St Michael's, Alaska, than it was to south-westward at St. Paul's, Behring Straits, and in connection therewith and with the prevailing winds, the temperature at St Paul's was 2°·9 below the average, whereas at St Michael's, where strong southerly winds prevailed, the temperature rose to 12° 0 about the normal. Hence whilst the continent of America presented striking contrasts in the distribution of pressure in December, 1878, it presented still more striking contrasts in the distribution of the temperature. Along Baffin's Bay the excess of the temperature above the normal was 14° 4, and at Behring Straits 12°·0, but in the south of Lake Michigan it was 9°·4 below it In this last case the change of temperature from November to December was probably unprecedented, the mean for November having been 13° 7 above the average (NATURE, vol. xxii. p. 516), whilst the December temperature was 9° 5 below it, the difference being 23° 2!

Turning now to Europe, it is seen that Iceland lay on the east side of the patch of high pressure which overspread that region, northerly winds consequently prevailed, and with them a lowering of the temperature to 7°·2 below the average. The contrast this offers to West Greenland is very instructive. In both localities pressure was unusually high, but they occupied different positions, the one on the east and the other on the west of the same area of high pressure, with the inevitable result, of opposite prevailing winds, accompanied in the one case with a temperature 14° 4 above the average, and in the other 7°·2 below it. Hence as regards the temperature at the surface of the earth, it is not the height of the barometer which rules, but the situation of the locality with respect to areas of high and low pressure, or to put it more popularly, it is the winds which are chiefly concerned in the distribution of the temperature

In Europe the area of lowest pressure occupied the southern shores of the North Sea, extending thence, though in a less pronounced form, to south-eastward Hence over the whole of Western Europe winds were north-easterly, northerly, and in the south-west of Europe westerly, thus everywhere, from the North Cape to the north of Italy, temperature was below the normal, in some cases very greatly so, the deficiency being 10° 4 in the south of Norway, and 12° 2 in the south of Scotland. This is the lowest monthly mean temperature known to have been recorded in Scotland since thermometric observations began to be made

On the other hand, to the east of this area of low pressure, winds were southerly, and consequently temperatures were high. In some localities in Russia an excess of about 15°·0 occurred, and even over a large proportion

of European Russia the excess rose to 9°.0. This region of high temperature extended eastward into Siberia, as far as the Irtish, or to where the centre of the greatest excess of pressure prevailed. To the eastward of this area of highest pressure winds were northerly, and low temperature prevailed over the whole of the eastern part of Asia, the deficiency at Nertchinsk, on the Upper Amoor, being 6°.8 below the normal. Here, again, just as happened in America, places having the atmospheric pressure equally high above their average presented the strongest contrasts of temperature. Thus at Nertchinsk pressure was 0.154 inch, and at Bogoslovsk 0.211 inch above their respective averages; but at Bogoslovsk, on the west side of the anticyclonic patch of high pressure, temperature was 15°.0 above, whereas at Nertchinsk on the east side it was 6°.8 below the average.

This time of the year being the summer of the southern hemisphere, pressure falls to the annual minimum in Australia, but during December, 1878, this annual low pressure was still further diminished. Pressure at this season also falls to the annual minimum in the North Pacific and North Atlantic, and we have seen that the low pressure of these regions was likewise still further diminished. But in the case of the Atlantic it was accompanied with a vitally important difference. The centre of lowest pressure of the North Atlantic in winter, which is commonly located about Iceland, was removed many hundreds of miles to southward, and an unwonted development of extraordinarily high pressure appeared to northward, overspreading the extensive region of, at least, Baffin's Bay, Greenland, Iceland, Faro, and Shetland.

It was to this region of high pressure that the extreme severity of our British weather at the time was due. This high-pressure region was intimately connected with, and in all likelihood occasioned directly by the atmospheric movements resulting from the enormous extent of low pressure to southward, with its large centres of still lower pressures in the United States, mid-Atlantic, and the North Sea, where pressures were respectively 0.146 inch, 0.322 inch, and 0.307 inch below the normals. If future inquiry establish such a direct connection between the areas of low and high pressure, it is evident that when we come to attempt, on scientific grounds, to forecast the weather of the coming season for the British Islands, we must look to the Atlantic for the data on which the forecast is to be based.

In the winter months pressure rises to the annual maximum over Central Asia, and in America about the region of the Rocky Mountains. In December 1878, however, pressure rose in both regions greatly above its usually very high average, the excess being nearly a quarter of an inch in the valleys of the Yenisei, Obi, Irtish, and Tobal, about lat. 60°, and 0.200 in America in the Columbia Valley. It follows therefore that with the singular outstanding exception of the high-pressure area of Greenland, the meteorological peculiarities which make December, 1878, so memorable, arose out of a distribution of the earth's atmosphere, essentially the same that commonly obtains at this time of the year, but the usual irregularities in the distribution of the pressure appeared in more pronounced characters.

We have now had the pleasure, through the courtesy of the late General Myer, of presenting our readers with a series of Twelve of these unique Weather Maps, which open out a new future to meteorology. The map for December, 1878, closes the series which appears in NATURE. The questions which a perusal of these maps raises are of first importance, whether we consider the atmospheric changes they disclose, these being repeatedly so vast as to stretch across four continents at one time, besides being often profoundly interesting from their influence both on the food supplies and the commercial intercourse of nations; or the large problems hereby presented, with hints toward their solution, which underlie physical geography, climatology, and other branches of atmospheric physics. We have thus had shown us from month to month, in a way not hitherto possible, the great atmospheric changes as influenced by oceans and continents, including the important parts played in bringing about these changes, by mountain ranges, extensive plateaux, and physically well defined river basins. Much yet, however, remains to be done, principally by extending the network of observation in order that the Weather Maps may show, in an approximately adequate manner, the meteorology also of the North Pacific and the southern hemisphere. Till this be done many fundamental questions cannot be discussed, such as the inter-relations of the different continents and oceans of the globe in their bearings on successive meteorological changes; and the important inquiry as to whether the pressure of the earth's atmosphere be practically a constant from month to month, and, if not, what are the conditions or forces on which the observed differences depend. For the bringing of this great international work to so happy a consummation, we look with confidence to the War Department of the United States, since this implies no more than a continuance of the same energy and enlightened liberality that have won for the Americans their high position in meteorology.

SEARLES VALENTINE WOOD

PALÆONTOLOGY has sustained a severe loss in the death of the veteran explorer of the English Pliocene deposits. Born towards the close of the last century, the late Mr. Wood was from an early age an ardent collector and student of the fossils so abundantly found in the crag-pits of East Anglia. At this period the facilities for collecting the fossils of the English Pliocene strata were much greater than at present. Fresh pits for the purpose of obtaining the shelly marls and sands, which were then extensively used for manure, were continually being opened in the counties of Norfolk and Suffolk, while at the present time the new chemical manures have caused the crag to be quite neglected by agriculturists. The geologist who visits the Eastern Counties at the present day to study the Pliocene has to content himself with such exposures as he can find in old pits, now often overgrown with vegetation and which are used as sheep-folds or stackyards.

Mr. Searles Wood, as he himself said, was born within sight of one crag-pit, he resided for a great part of his life in the crag country, and hoped to be buried within sight of a crag-pit.

In the year 1839 Mr. Searles Wood joined the Geological Society of London. The following year was marked by the establishment of the London Clay Club by seven earnest students of fossils, of whom we believe only Prof. John Morris, formerly of University College, London, still survives. The object which the members of the London-Clay Club set before themselves was the figuring and describing of the British Tertiary fossils.

The London-Clay Club was the forerunner of, and became merged in, the Palæontographical Society of London. This Society has published between thirty and forty volumes, which have appeared annually, and has accomplished a most valuable work in the illustration of our British fossils.

At a very early date Mr. Searles Wood and his friend the late Mr. Frederick Edwards agreed to divide between them the work of describing the mollusca of the English Tertiary formations. The absence of marine Miocene formations in this country divides our British Tertiaries into two great groups, the Older Tertiaries, in which the great majority of the mollusca belong to extinct species

and the Newer Tertiaries, or crags, in which a large proportion of the forms belong to species still living in the seas of some portion of the globe. Mr. Searles Wood naturally chose the latter group for his study, and Mr Edwards the former.

Upon the great task he had set before himself Mr. Searles Wood appears to have entered with characteristic energy, and in 1847 the Palæontographical Society was able to issue its first volume, which was entirely from the pen of Mr. Wood, and consisted of a description of the Crag Univalves, illustrated by twenty-one plates. In the years 1850, 1853, and 1855 Mr Searles Wood was able to publish the parts of his descriptions of the Crag Bivalves, illustrated by thirty-one plates

It soon became evident however that Mr. Edwards had taken upon his shoulders a lion's share of the work, and his friend Mr. Wood, having completed his own task, had to come to the aid of his fellow-student of the Tertiary fauna. It was then agreed that Edwards should complete his description of the Older Tertiary Univalves and that Wood should take up the description of the Bivalves Between the years 1859 and 1877 Mr Searles Wood published his descriptions of the Eocene Bivalves, illustrated by twenty-seven plates

Additional discoveries of fossils having afforded Mr. Wood fresh materials, a supplement to the "Crag Mollusca" was published by him between the years 1871 and 1873. This work was illustrated by twelve plates, and included a very valuable memoir on the strata from which the fossils were obtained, written by his son, Mr Searles V. Wood, jun , and Mr. Harmer of Norwich, who have both done so much good work in unravelling the complicated problems connected with the geology of East Anglia

Nor did the zeal of Mr. Wood allow him to rest even here; for in 1877, in spite of his advanced age, we find him commencing a supplement to his own and Edwards's work on the Eocene mollusca

In the year 1860 the Geological Society recognised the great services rendered to science by Mr. Searles Wood by presenting him with the blue-riband of geology, the Wollaston Medal Prof Phillips, who, as president of the year, handed the medal to Mr. Searles Wood, spoke in terms of well-merited praise of the important works which were the result of his patient, persevering, and successful labours.

Mr. Searles Wood and his friend Mr Edwards were remarkable examples of a type of scientific man which, happily for us, is far more common in this country than in any other. They were both engaged in the legal profession, but found time in their leisure hours to accomplish most excellent and useful scientific work. In the volumes of the Palæontographical Society the work of amateurs like Searles Wood, Edwards, and Davidson appears side by side with that of Richard Owen, Edward Forbes, and John Phillips. The subscriptions of the members cover the cost of engraving and printing, but all other charges are defrayed by the authors, who expect and receive no kind of payment for their important labours.

The valuable collection of Tertiary fossils made by Edwards and Searles Wood have fortunately been secured by the authorities of the British Museum for our National Collection. They will in the New Natural History Museum at South Kensington be more accessible for study than at Bloomsbury, and as they contain great numbers of type specimens, will be invaluable for purposes of reference to both British and foreign palæontologists

Mr. Searles Wood, as Treasurer of the Palæontographical Society, took the heartiest interest in its success, to which his own labours have to such a great extent contributed. Those who had the pleasure of a personal acquaintance with Mr. Searles Wood will ever remember the kindly and genial manners by which he was distinguished.

J. W. J.

NOTES

The following is the list of officers and council of the Royal Society nominated for the year ensuing The election will take place as usual on St Andrew's Day, November 30:—President — William Spottiswoode, M.A., D.C L., LL D , Treasurer—John Evans, D C L , LL D , Secretaries—Prof George Gabriel Stokes, M.A., D C.L., LL.D , Prof. Thomas Henry Huxley, LL.D , Foreign Secretary—Prof Alexander William Williamson, Ph.D.; other members of the Council—William Henry Barlow, Pres Inst. C.E ; Rev. Prof. Thomas George Bonney, M.A , George Busk, F.L S , Right Hon. Sir Richard Assheton Cross, Edwin Dunkin, V.P.R.A.S., Alexander John Ellis, B.A., Thomas Archer Hirst, Ph.D , William Huggins, D.C L , LL D , Prof John Marshall, F.R.C S., Prof. Daniel Oliver, F L S , Prof. Alfred Newton, M.A , Pres. C.P.S.; Prof. William Odling, M.B , V.P.C.S.; Henry Tibbats Stainton, F.G S.; Sir James Paget, D.C.L , William Henry Perkin, Sec C.S , Lieut-General Richard Strachey, R E , C.S I

It is proposed to erect a monument to Spallanzani in Scandiano, where the distinguished naturalist was born in 1729 A committee for the promotion of the scheme has been formed there, and at Reggio and Modena A monument in marble is contemplated, more or less splendid according to the sum provided, and it will be inaugurated on *August* 21, 1885 (if circumstances do not allow of an earlier inauguration). The committee meanwhile propose (if practicable) to publish a new and accurate edition of the writings of Spallanzani, including some which have not hitherto appeared. Contributions are hoped for not only from Italians, but from foreigners generally among whom the work and principles of Spallanzani are honoured.

M. Leon Humblot, a well-known *naturaliste-voyageur*, has just returned to Paris from Madagascar with large and valuable collections Amongst the living specimens (destined for the Menagerie of the Jardin des Plantes) are two examples of the aye-aye (*Chiromys madagascariensis*), which, M Humblot maintains, it is now more difficult to procure in Madagascar than in Europe, a pair of the rare carnivore *Cryptoprocta ferox*, and specimens of several of the smaller lemuroids. M. Humblot has also brought a valuable series of mammals and birds in skin and a large collection of orchids.

No naturalist who visits Florence should omit to inspect the series of Italian vertebrates which has been brought together in the Reale Istituto degli Studii superiori, by the exertions of Prof. H. H. Giglioli The collection embraces a series of authenticated specimens of mammals, birds, reptiles, batrachians, and fishes from every part of Italy and the adjoining districts which belong essentially to the same fauna, arranged in systematic order, and is far more complete than any other Italian collection of the same sort. Prof. Giglioli is preparing a catalogue of this collection as a basis for a new "Fauna Italica."

On the 1st inst a very fine Naval and Marine Engineering Exhibition was opened in the Corporation Galleries, Glasgow, altogether probably the finest exhibition of the kind we have had in this country. It is divided into five sections:—1 Naval architecture, including war vessels, sailing ships, paddle and screw steamers, yachts, dredges, and miscellaneous craft, boats and life-boats, (2) Marine engineering, including engines and parts of engines, boilers and boiler appliances, &c , governors , (3) Equipment, including anchors, boat-lowering apparatus, pumps and hydraulic machinery, steering-gear, telegraphs, windlasses, &c., machines and tools; (4) Navigation and harbour works; (5) Miscellaneous. The first section is of special interest, containing models of vessels of all ages and of all kinds, from

the *Henry Grace de Dieu* (A.D. 1514) down to the *Livadia*, many of these models having been lent by the Admiralty. Prefixed to the carefully compiled catalogue is a sketch of the rise and progress of steam navigation, more especially on the River Clyde, by Mr. W. J. Miller, C.E. The success of this exhibition is largely due to the energy and tact of the Curator of the Glasgow Industrial Museum, Mr. James Paton.

"THE Journal of the Indian Archipelago," founded and edited by the late J. R. Logan, which was published at Singapore, and ceased to appear some years since, has always been accepted by ethnologists as a valuable contribution to Malayan literature. Some of the early volumes, especially the first, have long been out of print, but Mr. David Logan, the son of the late editor, who was recently in England, has reprinted the scarce ones, thus enabling complete sets of the work to be obtained. Messrs. Trübner are, we believe, the agents in London.

THE very large and extensive entomological collection made by the late Jno Miers, F.R.S., has been presented to the Ashmolean Museum at Oxford, and is now being studied and incorporated by Prof. Westwood. This collection is particularly rich in Brazilian insects, and thus becomes peculiarly valuable for the Oxford collection, which was, compared with other regions, poor in the neotropical fauna.

THE British Museum will shortly acquire the splendid collection of Heteromerous Coleoptera formed by Mr. Frederick Bates.

SOME unbelievers insisted that the submarine crannog described by Mr Ussher at Ardmore, Co. Waterford, was only the remains of an old salmon weir, the late storms however seem to have set this theory at rest, as they have cut out the peat to seaward of the crannog and exposed the ancient kitchen midden, also additional piling not previously known.

AT the last meeting of the St. Petersburg Society of Naturalists Prof Wagner exhibited the hydroids and medusæ of the White Sea he has brought home, giving a detailed description of ten species of medusæ he has discovered in that sea.

AT the last meeting of the St. Petersburg Horticultural Society M Wolkenstein exhibited a new variety of vine which grows and fruits at Warsaw and Riga. M. Wolkenstein thinks it might fruit even at St Petersburg. We notice also a communication by Prof Regel on apples.

PROF. SILVANUS THOMPSON has an interesting article in the current number of *Brain* on "Optical Illusions of Motion."

WE learn from a paper published by M. Goulishambaroff in the *Journal* of the Russian Physical and Chemical Society, vol. xii. fasc. 5, that the whole of the naphtha region of the Apsheron Peninsula has an area of 4·3 square miles, which may be divided into two parts, that of Balakhany, which has given naphtha since the oldest times; and that of Sabountchi, which was explored only in 1873. The first part contains forty-seven naphtha-wells, of which only twenty-eight are productive, and yield together 6,192,000 lb. of naphtha daily. The density of this naphtha varies from 0·855 to 0·885, the average density being 0·8675; whilst the naphtha of the Sabountchi region has a density of from 0·820 to 0·860, and is extracted to an average quantity of 6,622,000 lb. The density varies from the most different causes: it varies in different wells, and usually it might be said that in the same bore the density diminishes with the depth; however, heavy naphtha is received also from very near to the surface; usually it becomes heavier when the evaporation of volatile gases is rendered easy by local circumstances. Contrary to established opinion, M. Goulishambaroff proves that the naphtha of the Apsheron Peninsula contains volatile products of a density of 0·62, but no use is made of them because of the imperfect means of purifying. The amount of photogene received varies very much, namely, from 15 to 85 per cent., the naphtha which has a density of 0·890 to 0·900 giving the lowest, and that of a density of 0·820 giving the highest, percentage; the most usual kinds of naphtha (density 0·863 to 0·870) usually give from 35 to 40 per cent. of photogene. It shows, he stated, however, that thorough measurements of the coefficient of dilatation of naphtha having not as yet been made, there remains a certain want of precision in the determinations of its specific weights.

ON the night of the 3rd inst. a magnificent display of aurora was seen from various parts of the country. We have received several communications on the subject. Mr. E. W. Prevost writes from Cirencester that the display was visible there from 6 p.m. up to about midnight. "The glow, which extended over an angle of about 100°, rose upwards to a height of 20°, leaving the central portion comparatively dark. Faint streamers occasionally showed themselves, reaching 35° in height. A shifting of the streamers from east to west was noticeable, the illuminated arc being at times extinguished on the eastern side, this extinction progressing slowly towards the centre of the arc, when the light would reappear at the eastern side. At no time, as far as I observed, did the light disappear on the western side, the colour was of a greenish yellow and the wind due north." From Bootham, York, November 3, Mr J. Edmund Clarke writes: "There is quite a brilliant aurora this evening, first noticed about 6.30 as a diffused light shifting from north-east to south-west, with occasional streamers. Now (7.30-8.45 p.m.) it forms a low bright arch of considerable intensity. I said 'first seen about 6.30,' but at 4.40 I called the attention of a friend to some sharply defined red streamers in the north-east, which I then took to be sunlight. On August 12 last, about ½ to ¾ hour after sunset, my attention was called to streamers precisely similar, in every respect like those of the aurora. But careful observation showed that these were certainly radiating *from* the sun, and not converging *towards* the magnetic pole. It is certainly my impression that such was the case to-night, but being busy I did not take any special pains to ascertain. Of course this double coincidence may be a pure accident, but is it not possible that the minute substances reflecting the solar rays are actually modified by the electric field, so as to produce this remarkably distinct variety of rays? P.S.—8 p.m. Brilliant streamers from the bright arch, with some corruscations." Prof. Reilly, of the Royal College of Science for Ireland, writes that in Dublin the display was very fine. "The principal beam appeared as if slowly moving from west to east, and had a direction quite parallel to the pointers of the Great Bear. It reached at the time when seen quite up to the Polar Star. The lights were observed at earlier hours, one person having mentioned to me 6 o'clock p.m." In Orkney it showed itself as one of the most brilliant displays of aurora borealis seen for a long time. The whole northern horizon was one dark mass of clouds with a sharply defined edge, and from these the aurora shot up in beautiful coloured streams to nearly the zenith, covering the clear sky above the clouds from north-east round to north-west. Occasionally the aurora took the form of a gigantic rainbow, and the light was as bright as moonlight.

A SMART shock of earthquake occurred on the 9th inst. throughout Southern Austria, from Vienna to the Adriatic and the frontiers of Bosnia. In the capital a rather violent shock was felt at a quarter to eight. Numerous telegrams have been received by the Meteorological Bureau at Vienna stating that shocks were felt at Serajevo, Derwenta, Brod, Pola, Trieste, Zilli, Klagenfurt, Fünfkirchen, Odenburg, Marburg, Laibach, and Gross-Kanischa. In Agram, the capital of Croatia, three shocks of earthquake occurred, a period of an hour intervening between the second

and third. One of them, which lasted ten seconds, was so powerful that not a single house remained uninjured. A general panic reigns in the town. Many of the inhabitants, including the Cardinal-Archbishop, have taken to flight It is impossible to estimate the whole extent of the damage. The number of persons injured is at present estimated at thirty.

THE eruption of Vesuvius continues to increase in activity Two large streams of lava are at present (November 8) flowing from the crater to the base of the cone

IN Prof. Huxley's article on the *Challenger* Publications last week, line 11 from top of p 2, col 2, should read "*direct* and but little modified descendants," instead of "*dried*," &c

OUR ASTRONOMICAL COLUMN

HARTWIG'S COMET (1880 *d*).—In a circular issued by Prof. Winnecke from the Observatory of Strasburg on the 1st inst., he gives reasons for assuming that the comet detected by Dr. Hartwig on September 29 may have a much shorter period than was conjectured in his first circular On calculating parabolic elements from the Strasburg observations of September 29 and October 8, and one by Prof Auwers at Berlin on October 17, MM Ambronn and Wislicenus, students in the University of Strasburg, found the middle observation could not be more closely represented than with an error of something over two minutes of arc. Prof Winnecke, as was stated in our previous notice, considered he had reason for suspecting the identity of Hartwig's comet with that of 1506, and a further examination of the historical descriptions has led him to direct attention to the comets of 1382, 1444, and 1569, and with the perihelion passage fixed to July 13, 1444, and October 15, 1569, he finds geocentric positions which he regards as in sufficient agreement with the records. A period of revolution of about 62½ years is therefore obtained, and an ellipse with this period has been adapted by Dr. Schur and Dr. Hartwig to the observations on September 29 and October 14 and 24. The resulting elements are as follow :—

Perihelion Passage, 1880, September 6 58949 M.T. at Berlin.

Longitude of perihelion		83 33 28	M. Eq. 1880 0
„ ascending node		44 33 30	
Inclination	...	38 8 56	
Log. excentricity	.	9 990180	
Log semi axis major		1 196457	
Log mean diurnal motion		1 755321	

The error of the place deduced from this ellipse on October 14 is + 28″ in longitude and the same in latitude, and it is remarked that the error in longitude does not admit of being destroyed without an increase of error in latitude. This, however, Prof. Winnecke suggests, may arise from the assumed period of 62½ years being really a multiple of the true one The comet approaches near to the orbit of Mercury at the ascending node, though at the present time not sufficiently close to occasion any change in the character of the orbit Still at some past epoch the effect of perturbation may have brought the orbits into coincidence or nearly so, and Prof. Winnecke hints that the planet Mercury might have been the means of impressing an elliptical form on the comet's orbit.

It is clearly a case in which those observers who are in the possession of very powerful instruments may render most material service towards deciding whether we have to do with a comet of comparatively short period. If it is practicable to secure good observations for position after the next period of moonlight, it may then be possible to obtain evidence *pro* or *con*, by direct computation of the orbit, though unfortunately observations did not commence until the comet had reached the extremity of the parameter, or in other words had attained an angular distance of 90° past the perihelion point.

DISCOVERY OF A COMET.—Lord Lindsay notifies the discovery of a comet at his observatory, Dunecht, during the night of the 7th inst., by Mr Lohse in the constellation Lacerta; the position at 15h. 30m. in R.A. 22h. 45m. 54s., Declination 42° 33′ 7, daily motion in R.A. + 6m 58s., in Decl. + 1° 8′. This is far from any position which the expected comet of 1812 could occupy on the above date

CERASKI'S VARIABLE STAR —Mr Knott obtained a very complete observation of the descending and ascending light curve of this newly-detected variable on November 2; the minimum appears to have occurred about 11h. G M T. The period will be somewhat less than 2½ days.

PHYSICAL NOTES

PROF. LORENZ has given in *Wied. Ann*, No 9, a development of his theory of "refraction-constants" (published before in Danish), and described experiments bearing on it. The problem contemplated was to find that function of the refractive index, freed from dispersion, and of the density of a body, which is constant with varying density of the body, supposing the molecules themselves unchanged. It is assumed that bodies consist of molecules in whose intervals light is propagated with the same velocity as in vacuous space, further, that the bodies are isotropic, and their molecules of spherical form. Herr Lorenz arrives at a simple expression for the refraction-constant, the constancy of which, as also the correctness of the assumption as to light moving with the same velocity in the intervals of molecules as in vacuo, had to be proved He determined the refraction constants of several bodies in the liquid and the vaporous states, viz, ethylic ether, ethylic alcohol, water, chloroform, ethylic iodide, ethylic acetate, and sulphide of carbon. The refraction was determined with sodium and lithium light, and at temperatures of 10°, 20°, and 100°. He found that in passage of the substances from the liquid to the vaporous state the refraction-constant varies very little (only about 5 per cent at most) Dispersion also showed great constancy. Another Danish physicist, K. Prytz, has extended the inquiry to some ten other substances (*loc. cit*), and confirmed the assumption of refraction constants.

WITH regard to electricity, Herr Hoorweg (*Wied Ann.*, No 9) divides all bodies into two groups, (*a*) those in which the conductivity rises with the temperature (dielectrics), and (*b*) those in which it decreases with rise of temperature (adielectrics). He endeavours to prove by experiment (1) that both dielectric bodies with adielectric, and adelectric with each other, yield contact electricity, (2) that this electricity has always the same sign as that which arises with gentle friction or pressure. (The sometimes different action of strong friction is ascribed to the influence of the raising of temperature.) Not only does electricity arise through the different heat-motion at the places of contact of two heterogeneous substances, but this cause is fully sufficient to explain all development of electricity.

HERR NARR has lately obtained some interesting results in experimenting further on the behaviour of electricity in gases, and especially *in vacuo* (*Wied. Ann*, No 9). In the middle of a hollow brass sphere on a glass support was suspended a metallic ball by means of a platinum wire passing (insulated) through a metallic stopper to an electrometer Vacua could be produced in the sphere A charge of electricity imparted to the conducting system underwent the same process of dispersion *in vacuo* as where the space was full of gas. The outer surface of the hollow sphere, one minute and also one hour after the charging, had the same electricity as the conducting system Herr Narr further finds that the process of dispersion in gas-filled space is not perceptibly influenced by the hollow sphere being insulated or being connected to earth, if the original charging be done while the sphere is connected to earth; the dispersion constant diminishes in both cases, at least at the beginning But if the conducting system be charged while the hollow sphere is insulated, the latter has in this state one minute, and likewise one hour to one hour and a half after, electricity of the same sign with the conducting system, and the first connection of the hollow sphere to earth occasions a temporary outflow. Herr Narr shows reasons for believing that the electricity on the hollow sphere finds its way through the gas space.

A NEW series of experiments of extended range, by Herr Roth, on the compressibility of gases, is described in *Wied Ann.*, No. 9. The relations between pressure, volume, and temperature, in the case of carbonic acid, sulphuric acid, ammonia, and ethylene, are studied. The results are mainly confirmatory of van der Waal's formulæ.

A NEW balance designed to be easily transportable, light, and yet stable, without fixing to the table, and to serve in inspection of widely various weights (by Government officials in Hungary), was lately brought before the Buda-Pesth Academy by Herr von Kruspèr (see *Wied. Beibl.* No. 9, p 638) Among other features,

the prism-shaped steel bed, on which the middle knife-edge rests, is easily drawn out with the finger from the swallow-tail shaped rollers between which it is passed in the body of the balance. The beam can thus be easily removed and replaced. The balance rests on four feet. The stopping and raising arrangement is contained in a horizontal frame. Each weighing scale hangs on a conical point. Passing on to the reading, we find that the accuracy with which the balance works is, with 20 kg. weight, 2mg., with 500, 3½ mg.; and this is gained by substituting for the pointer an optical arrangement on the beam, consisting of two achromatic glass prisms, which render parallel the rays from opposite directions and send them to a telescope placed before the balance. At the two sides of the balance, about 2m to 4m from the middle knife-edge, two scales are set (best on the walls of the room); the images of these scales move in the field of the telescope beside each other in opposite directions, and so the corresponding divisions can be read off. These readings are independent of vibrations of the telescope, and are much more exact than those with telescope and cross threads, not to speak of the common pointer. The arrangement also permits of the centre of gravity of the balance being placed lower, the stability increased, &c. The weight of the balance is scarcely 20 kg, though both scales can carry 20 kg. weight

EXPERIMENTS by Forbes in 1831 and by some others since seemed to warrant the view, now commonly held, that the metals fall into the same series as regards conduction of electricity and conduction of heat, that the quotient of the heat conductivity by electric conductivity is nearly constant. Herr H. F. Weber, inclined to doubt this as contradicting the view (proved for gases and liquids) that the amount of heat transferred within a substance from layer to layer is most intimately connected with the specific heat of unit volume, made new experiments in this relation (which he has described to the Berlin Academy). He measured the heat-conduction by observing the cooling of various metal rings in a space at constant temperature, and the electric conducting power of the same rings, by noting their deadening effect on the oscillations of a magnet. The result confirmed his anticipations, the quotient of heat-conduction by electric conduction being found in the closest connection with the specific heat of unit volume. Experiments by a different electrical method for metals conducting electricity badly (lead, bismuth, &c.) and for mercury gave the same result. (Ten metals in all were examined.) On the other hand, non-metallic conductors of electricity do not show the relation in question, *e.g.* the heat-conduction of carbon is at least twenty to thirty times greater than that calculated from the electric conductivity and the specific heat. Thus the relation seems to be connected with the metallic nature of the substance. Herr Weber found the heat-conducting power of all the solid metals examined to decrease with increasing temperature, but at a considerably less rate than the electric conductivity. He further offers explanations of the erroneous view adopted, noting, *inter alia*, that the experiments in one case, though exact, were on too few metals, and these had nearly the same specific heat.

PROF. R. B. WARDER of Haverford College (Pennsylvania) and Mr. W. P. Shipley have investigated the configurations assumed by floating magnets in a magnetic fluid. They have modified Prof Mayer's original experiment by surrounding the vessel of water with a coil of wire traversed by a current, thus producing a field of force which, while still symmetrical about the centre, differs in several respects, the lines of force not being so greatly concentrated near the centre. Diagrams of various configurations are given by these experimenters in the *American Journal of Science* for October. As even a single one-fluid cell produces a current sufficient to show these results, they ought to be easy of repetition.

A COMPREHENSIVE memoir on the theory of the radiometer, by M. Mees, appears in the *Proceedings* of the Amsterdam Academy, and (in pretty full abstract) in *Wied. Beibl.*, No 7. The author, after criticising the various theories that have been enumerated, which he arranges in three classes, offers his own explanation of the phenomena (which cannot be briefly stated here).

A FEW months ago we drew attention to certain results published by Herr Exner of Vienna, relative to thermoelectricity, and which were at variance with all the body of evidence existing in that branch of science. Herr Exner had in fact asserted that an antimony-bismuth couple possesses thermoelectric powers only so long as one of the two metals is in contact with oxygen or with a gas capable of acting on one of them. The wish we then expressed that some independent observations might be made by other physicists has met with a response across the Atlantic. Prof. C. A. Young of Princeton, N J., communicated to the recent meeting of the American Association a paper on the thermoelectric power of a platinum-iron couple *in vacuo*. The crucial experiment was made with an exhausted glass tube containing an iron wire with platinum terminals, the terminals being again fastened to iron wires leading to a galvanometer. The tube was exhausted to one millionth of an atmosphere. On laying the apparatus in the sunlight and alternately shading the internal or external junctions an electromotive force could be produced, which was found to be equal in every case. The conclusion Prof. Young draws from the experiment is that Exner is wrong in his statement that thermoelectric electromotive force is due to the action of the gaseous media in which the metals are plunged. The experiment was conducted in Mr. Edison's laboratory at Menlo Park.

GEOGRAPHICAL NOTES

THE glacier of the Zarafshan, one of the greatest in Central Asia, which has hitherto been very imperfectly known, was explored during this summer by MM. Mushketoff, geologist, and Ivanoff. The exploration was quite successful, and at the last meeting, October 26, of the Mineralogical Society at St Petersburg, Prof. Mushketoff read a paper on his explorations. The lower extremity of the glacier is at the height of 9000 feet. The Galtcha people, who inhabit the upper valley of the Zarafshan, have never ascended the glacier, they say that on the summit of it there are two great pillars of stone, between which the traveller must go, and that the pillars would certainly crush together if any one ventured into the icy solitude. On August 25 the party began the ascent of the glacier on a very steep slope covered with blocks and moraines. A tunnel, no less than 3500 feet long, runs under the glacier, being the bed of the Macha River. After two days' travel the party had done seven miles on the glacier. The temperature during the day was as high as 40° Cels., and during the night as low as − 8°, some Galtchas who accompanied the party fell ill with fever. On the fourth day the party reached the first watershed, or rather the first iceshed, the whole length of the glacier to this point was sixteen miles, the width being one mile, six other glaciers, each of which is greater than the greatest Alpine glaciers, fed the principal one. At the head of it there is a wide *cirque* opening to the east; several peaks around it reach 20,000 feet. The descent on the other slope of the mountain ridge was far more steep and difficult than the ascent, the crevasses are very numerous and the glacier has several great "ice-falls," the inclination of which is no less than 50 degrees; the party was compelled to make use of small anchors and to cut steps in the ice. Two men were unwell and quite unable to go further when the party reached the foot of the eastern slope, after a very difficult journey.

THE last number of the *Izvestya* of the Russian Geographical Society contains a letter from Dr Miklukho-Maclay. After having visited the islands of New Caledonia, Lifu, New Hebrides, Admiralty, Louisiade, &c., he reached, about the end of January, 1880, the south-eastern coast of New Guinea, here he explored several points of the coast, and thence went to the islands of the Torres Strait and to Somerset, to study the population of Northern Australia. On his voyage from Vaihan Island to Sydney he stopped at several points of the eastern coast. From Sydney M. Maclay proposes to go to Japan, and thence to return to Russia. During his stay in Brisbane he was very kindly received by the local government and by private persons, who have much facilitated his anatomical studies by allowing him to work in the old museum and to make use of the photography of the topographical department. The journey in the interior of Queensland was very much facilitated by the cordial reception he received from the squatters, and by the kind permission to travel gratuitously along all the railways. M. Maclay expresses, in a letter addressed to the *Golos*, his thanks to the Australians for the reception he met from them, and wishes that all men of science were so kindly received in Russia. On August 12 he was in the house of J. B. Bell at Jimbor, near Dalby. The Russian public subscription has already reached 606*l*. which he received at Sydney.

A GOOD example is being set by the Tashkent College. During the summer fourteen pupils of the College, under the

direction of their Professor of Natural History, M. Shelting, made an excursion in the Ala taou Mountains. Numerous measurements of heights were made during the journey, good zoological, botanical, and geological collections, for the Museum of the College, were made, and a detailed diary of the excursion was kept by the scholars. The students of the Tashkent Normal School, as well as the pupils of the College of Verny, have also made scientific journeys for the exploration of the neighbourhood, and we learn that the College of Orenburg has requested tickets at reduced rates from the railway company for undertaking next summer a series of explorations in that little known but very interesting province. We cannot but wish that the colleges and schools of Western Europe would follow these examples; what an excellent training in natural science might thus be given, and what a mass of valuable information might be collected

THE members of the scientific expedition which was sent out by the St. Petersburg and Moscow Societies of Naturalists for the exploration of the White Sea and of the Murmanian coast of the Arctic Ocean, and which consisted of Professors Wagner, Bogdanoff, Tsenkovsky, and eight students of the University, have returned after having done some very successful work; they bring home very rich zoological and geological collections. Professors Wagner and Tsenkovsky stayed throughout the summer at the Solovetsky Islands, M. Lavroff in Kandalaksha Bay; Prof Bogdanoff travelled along the whole coast to Vadso; MM. Koudravtreff and Pleske, geologists, have travelled from Kandalaksha to Kola, others have explored the flora and the fauna of the ocean, Prof. Bogdanoff has also studied the fishing.

BARON A. VON HUGEL is now engaged in writing a work upon Fiji, where he travelled and spent some time, making extremely extensive and complete anthropological collections The work will be more particularly an ethnological one, and most of the weapons, fabrics, and other ethnographic articles are being figured to accompany the text The crania collected by Baron von Hugel have already been acquired by the Royal College of Surgeons, and exhaustively described by Prof. Flower.

WE notice the appearance of an important work published by the Russian Geographical and Economical Societies in the first volume of a "Collection of Materials for the Knowledge of the Russian Commune." It contains detailed descriptions of the communes of the Governments Ryazan, by M Semenoff, president of the Russian Geographical Society, MM Litochenko, Zlatovratsky, Mme. Yakouchkin, &c, a very complete bibliographical index of the literature concerning the communes of Russia and of Western Europe.

A TELEGRAM has been received at St. Petersburg from Col. Prejevalsky, dated from Urga, the 1st inst., stating that during the spring and summer of this year he surveyed a part of the basin of the Upper Hoang-ho and the Lake Koko Nor. He also passed through Alashan, in the centre of the Gobi desert, to Urga. Col Prejevalsky states that during the expedition he traversed a distance of 7200 versts, and that he has succeeded in obtaining valuable scientific results

THE death is announced, on his passage home from West Africa, of Count de Semellé, who has been recently exploring on the Lower Niger.

THE new *Bulletin* of the Société Khédiviale de Géographie contains a paper by General Purdy-Pacha on the country between Dara and Henfiah El Nabass, together with a map of that portion of Darfur, and another on Medina twenty years ago, by Col. Mohamed Sadik-Bey, illustrated by two engravings.

THE Church Missionary Society have received news that the Rev. P. O'Flaherty, their new agent in Uganda, and Mr. C. Stokes, with the Waganda chiefs and a large caravan, started from Saadani for the interior on August 9, but in little more than three weeks Mr. O'Flaherty was taken ill at Kidete, and will be unable to proceed to the Victoria Nyanza at present.

THE same Society have also received letters from various members of the Nyanza mission, giving a much more favourable report of their position in Uganda than had reached England some time back. Rev. G. Litchfield had in consequence of ill-health made an attempt to push northwards to Lado, in order to consult Dr. Emin Effendi. In this he unfortunately failed, being stopped by Kabba Rega, the king of Unyoro, who has seized M'ruli and other posts vacated by the Egyptians since Col. Gordon's departure. Mr. Litchfield accordingly returned to Rubaga, and, crossing the lake, proceeded to Upui, hoping eventually to get to Upwapwa, where Dr. Baxter is stationed.

MESSRS CAMERON AND PIGOTT, of the China Inland Mission, have made a journey of eight months through a great part of Manchuria and a portion of Mongolia. From the treaty port of Newchwang Mr Pigott went on to Moukden, while Mr Cameron proceeded along the coast in an easterly direction by the borders of Corea, and then northwards to Moukden. They next journeyed through part of Mongolia into Kirin, which at first they found fertile and well-wooded, but afterwards the country became wild, poor, and sparsely populated. The city of Kirin was reached by a long steep descent through fine scenery Fine teams of oxen were here met with, comparing favourably with some of our best breeds. After spending a few days at Kirin the two missionaries returned overland to Peking, passing the Great Wall at Shan hai kwan or Ling-yu-hsien

MESSRS. RILEY AND CLARKE, of the same Society's station at Chungking, have recently paid a visit to some Lolo villages in Southern Szechuen These mountaineers for the most part live in inaccessible fastnesses beyond the reach of the Chinese authorities, and are not confined to Szechuen and Yunnan, but under the designations of Laos and sundry other names are found throughout the extensive regions of Annam, Siam, and Burmah. Hardly anything is yet known of the Chinese Lolos and their manners and customs, but before long the agents of the China Inland Mission in the south-west will, it may be hoped, find means to collect information regarding them.

ON A DISTURBING INFINITY IN LORD RAYLEIGH'S SOLUTION FOR WAVES IN A PLANE VORTEX STRATUM[1]

LORD RAYLEIGH'S solution involves a formula equivalent to $\frac{d^2 v}{dy^2} \left(m^2 + \frac{\frac{d^2 T}{dy^2}}{T - \frac{n}{m}} \right) v = 0$

Where v denotes the maximum value of the y-component of velocity,

„ m „ a constant such that $\frac{2\pi}{m}$ is the wave-length,

„ T „ the translational velocity of the vortex-stratum when undisturbed, which is in the x-direction, and is a function of y,

„ n „ the vibrational speed, or a constant such that $\frac{2\pi}{n}$ is the period.

Now a vortex stratum is stable, if on one side it is bounded by a fixed plane, and if the vorticity (or value of $\frac{dT}{dy}$) diminishes as we travel (ideally) from this plane, except in places (if any) where it is constant.

To fulfil this condition, suppose a fixed bounding plane to contain ox and be perpendicular to oy, and let $\frac{dT}{dy}$ have its greatest value when $y = o$, and decrease continuously, or by one or more abrupt changes, from this value, to zero at $y = a$ and for all greater values of y

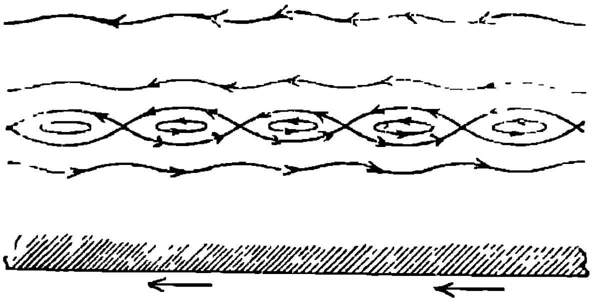
It is easily proved that the wave-velocity, whatever be the wave-length, is intermediate between the greatest and least values of T. Hence for a certain value of y between 0 and a, the translational velocity is equal to the wave velocity, or $T = \frac{n}{m}$. Hence for this value of y the second term within the bracket in Lord Rayleigh's formula is infinite unless, for the same value of y, $\frac{d^2 T}{dy^2}$ vanishes

We evade entirely the consideration of this infinity if we take only the case of a layer of constant vorticity $\left(\frac{dT}{dy} = \text{constant}\right.$ from $y = o$ to $\left.y = a\right)$, as for this case the formula is simply

$$\frac{d^2 v}{dy^2} = m^2 v,$$

[1] By Sir William Thomson British Association, Swansea, Section A

but the interpretation of the infinity which occurs in the more comprehensive formula suggests an examination of the stream-lines by which its interpretation becomes obvious, and which proves that even in the case of constant vorticity the motion has a startlingly peculiar character at the place where the translational velocity is equal to the wave velocity. This peculiarity is represented by the annexed diagram, which is most easily understood



if we imagine the translational velocities at $y = 0$ and $y = a$ to be in opposite directions, and of such magnitude that the wave velocity is zero, so that we have the case of standing waves. For this case the stream-lines are as represented in the annexed diagram, in which the region of translational velocity greater than wave-propagational velocity is separated from the region of translational velocity less than wave propagational velocity by a cat's-eye border pattern of elliptic whirls.

MINERAL RESOURCES OF NEWFOUNDLAND

ORES of copper have been found in all the older formations in Newfoundland, from the Laurentian gneiss at the base, to the Carboniferous series at the summit, the qualities of which vary greatly with the age and condition of the rocks with which they are associated. Thus in the Laurentian series the rich ores of variegated and sometimes grey sulphide of copper are more frequent than any other, and are for the most part in white quartz veins intersecting the strata, but while these ores have in many cases been found on analysis to yield at the rate of from 50 to 70 per cent. of metal, the quantities available at any one place hitherto tested have never yet been found sufficient to warrant an outlay of capital.

In the succeeding series, which I conceive to be the equivalent of the *Huronian* of *Canada*, and have provisionally called *intermediate*, as being intermediately situated between rocks of the Laurentian and Primordial Silurian ages, very rich ores of copper are likewise well known at many parts, chiefly in white quartz veins, and also in faults and dislocations, particularly near the junction with the fossiliferous Primordial, in which cases the indications may sometimes be regarded as favourable for the probable future development of mines. Several attempts have already been made in this direction at various parts of the distribution of the series, but except at a few places, chiefly near the junction with the newer formations, with but slender prospect of a successful issue.

By reference to the Custom House returns of exports I find that the amount and value of copper ore shipped at St John's between the years 1854 and 1864 inclusive was as follows:— Ore, 627½ tons, value \$22,980 = 4,596*l* sterling. The places where this ore was raised are not specified, but I believe it was all derived from rocks of intermediate age, by which the greater part of the Peninsula of Avalon is occupied.

In addition to the above export from St John's, 544 tons, valued at \$19,179 were exported between the years 1875 and 1879; but a considerable, if not the larger portion of this ore was produced from Tilt Cove and other of the early openings in Notre Dame Bay.

Although the presence of copper is frequently indicated by stains of green carbonate and small nests of yellow sulphuret in the lower Primordial strata, I am not aware of any instances where the ores occur in mass, or in intersecting veins or lodes, except it may be close to their immediate junction with the older series on which they repose unconformably or butt up against in faults. At some parts of their distribution, such as in the islands of Conception Bay, these older Silurian rocks are but very little disturbed, resting in nearly a horizontal attitude, and scarcely at all altered, at other parts, such as Trinity Bay, St. Mary's Bay, Langlois Island of the Miquelons and elsewhere, they are greatly disturbed by intrusions of igneous rock, and occasionally to some extent metamorphosed, but they are almost everywhere crowded with organic remains, the types of which indicate the ages they represent, to extend from the horizon of Primordial or Cambrian to the newer Potsdam Group of the United States and Canada. Strata representative of Potsdam, Calciferous, and Levis ages, containing abundance of typical fossils, are extensively displayed on the western and northern parts of the island, the former in many cases resting directly on Laurentian gneiss unconformably, but, except it may be to a very limited extent in Canada Bay, near the Cloud Mountains, I am not aware of any deposits older than the Potsdam at these parts, nor have I seen indications of the presence of the Huronian or intermediate system north of Bonavista Bay, or anywhere near the western shores. Galena in calcareous veins is of frequent occurrence in these Lower Silurian rocks, but except in small isolated crystals or patches the ores of copper are particularly rare, and in no case such as to be considered economically valuable.

But the cupriferous formations proper of Newfoundland, according to my view of the structure, lie unconformably above all the former, and consist mainly of a set of metamorphic and igneous rocks, corresponding exactly in mineral character and condition with the rocks of the Eastern Townships of Canada described by Sir Wm. Logan under the title of the Quebec Group. I am quite aware that these views, as regards the structure, are at variance with those entertained by several distinguished geologists in Canada (whose opinions, however, do not seem to be very unanimous on the subject), and there cannot be a doubt that in many cases the evidences appear to be so contradictory at different localities that the difficulties in arriving at the truth are exceedingly great. Nevertheless, so far as my own observations go, and I have studied the succession at nearly all parts of their distribution in Newfoundland, I am led to the conclusion that the stratigraphical position of this metamorphic group belongs to a horizon intermediate between the Calciferous and Hudson River group, probably chiefly of Chazy age, which is in accord with the structure of Sir W. E. Logan.

The group consists of chloritic, dioritic, and felsite slates, interstratified with compact diorites, bands of red jasper, dolomites, great masses of serpentine, or serpentinous rock, and volcanic products. In nearly all these rocks the ores of copper are more or less disseminated, but it is amongst the schistose portions, especially the clorite slates, that they seem to be most abundant, and it is in rocks of that quality chiefly where the principal mining operations have hitherto been conducted. At some parts of the distribution these rocks are distinctly stratified, the lines of deposit being well displayed in layers of different quality: beds of jasper, conglomerate, &c. The whole series is magnesian, more or less, but particularly towards the top, which appears to be the horizon of the serpentinous masses, with large accumulations of volcanic ash. Towards the base the rocks become calcareous, the cliffs of strata much incrusted with carbonate of lime, and some strata of a pure white crystalline limestone occur which are fossiliferous. The fossils are too obscure to be identified with certainty, but one form bears a strong resemblance to a *Maclurea*, another to a *Bellerophon*, a third to a *Murchisonia*, and some rather large-sized *Encrinite* stems. Near the horizon of this limestone moreover we find a set of black slates which contain graptolites. Vast intrusive masses of granitoid rock, and great dykes of greenstone melaphyre and other traps intersect the formation.

The only mines of importance in active operation up to the present time are all situated in Notre Dame Bay, and these are Union Mine Tilt Cove, Betts Cove Mine, Colchester, in southwest arm of Green Bay, Little Bay Mine, Rabbit's Arm, and Seal Bay. Many openings and minor workings have also been made at various parts of the bay, at each of which the ores of copper were more or less indicated, some of which may eventually, when capital and skilled labour are brought to bear, be found sufficiently remunerative to be worked to advantage.

It will be seen by the annexed memoranda that the total value of the copper and nickel ore extracted since 1854, but by far the larger proportion since 1864, when the Union Mine Tilt Cove was first opened by Mr. Smith McKay, amounts to nearly one million sterling.

Memoranda showing the Quantities and Values of Copper and Nickel Ores exported from the Island of Newfoundland in the undermentioned Years

Years.	Parts cleared from	Copper	Nickel	Value	Value of nickel ore
		Tons	Tons	Dollars	Dollars
1854 to 1864	St John's	627½[1]		22,980	
1875 to 1879	,,	544½[2]		19,179	
	Total St. John's	1,172		42,159	
1869	Union Mine Tilt Cove	5,938	30	190,016	7,200
1870	,,	4,218	88	134,976	8,800
1871	,,	1,924	7	61,568	700
1872	,,	4,774[3]	8	152,768	25,60
1873	,,	5,414	233	189,490	9,320
1874	,,	4,346	—	104,304	—
1875	,,	4,838	17	179,006	1,360
1876	,,	6,464	28	232,704	2,800
1877	,,	5,389	—	194,004	—
1878	,,	4,450	—	97,966	—
1879	,,	1,964	—	35,352	—
	Total Tilt Cove	49,719	411	1,572,154	32,740
1875	Bett's Cove	6,280		232,360	
1876	,,	18,670		456,481	
1877	,,	42,065		1,093,768	
1878	,,	31,370		690,140	
1878	Regulus	750		34,500	
1879	,,	26,421½		475,587	
	Total Bett's Cove	125,556½		2,982,836	

The ores returned for 1878–79 were largely derived from Little Bay Mine and partly from Colchester, all belonging to the Bett's Cove Mining Company.

Thus the total value of the ores of copper and nickel exported since 1854 amounts to $4,629,889, or nearly £1,000,000 sterling.

ALEX. MURRAY

[1] Chiefly from Huronian rocks
[2] Partly from openings in Notre Dame Bay.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

CAMBRIDGE.—In Groups C and E of the Higher Local Examination this year there were respectively fifty-four and ninety-nine candidates, five obtained a first class in Group C (Mathematics) and eight a first class in Group E (Natural Science), nine candidates failed in Group C, and twenty-six failed in Group E. Three candidates answered the questions in Differential and Integral Calculus, and showed considerable knowledge In botany a fair average of proficiency was attained, in geology the papers were below the average In zoology inferior text-books had been too much preferred, to the exclusion very largely of practical work The work in chemistry was unequal, but some candidates showed a very good acquaintance with the details of manipulation. Physics can scarcely be said as yet to be studied by the candidates. In physiology the answers were in some cases accurate and to the point, but the majority of candidates failed.

The elections to the Council of the Senate were made on Monday, and show in a very practical manner that residents are in favour of considerable improvement in University matters. Only one member who approves of the retention of Greek as a universal subject in the "Little-go" was elected, viz, Mr. G. F Browne, whose place in the Council is due to his active work in connection with the University Local Examinations and his knowledge of the intentions of the University Commissioners, as one of their secretaries.

Dr Phear, Professors Cayley and Liveing, and Mr. Peile, are among those who were elected to the Council well known for their scientific eminence and breadth of view.

Prof. Stokes, Lord Rayleigh, and Mr. Vines were added to the Council of the Philosophical Society at its annual meeting.

Mr Forbes, Prosector to the Zoological Society, has been elected to a Fellowship at St. John's College

AT an examination held on Wednesday, October 27th ult, Mr. M Milburn, of Longtoun, was elected to a vacant bursary in connection with the "Young" Chair of Technical Chemistry, Anderson's College, Glasgow. The bursary, which is of the value of 50*l.*, and tenable for three years, is the gift of Mr. James Young, LL D., F R.S., of Kelly and Dullis, founder of the Chair.

SCIENTIFIC SERIALS

Journal de Physique, October.—Experimental verification by S. Carnot, of the principle he discovered, by M Lippmann.—Apparatus and experiments for elementary demonstration in optics, by M Gariel —Influence of velocity of propagation of sound in the shock of elastic bodies, by M. Flie —New form of plates for air pumps, by M Terquem —*Proceedings* of the Physical Society of St. Petersburg (including papers, in abstract, on the chemical and photographic action of light, the transmission of the current in water with unequal platina electrodes, variations of volume and coefficient of elasticity of palladium and its alloys under the influence of absorbed hydrogen, &c.)

Rivista Scientifico Industriale, No 18, September 30 —On the relation between terrestrial storms and the planetary relations of the solar system, by Prof. Zenger.—Excursions (geological) in the neighbourhood of Modica, by Prof Lancetta.—Palæontological studies in Bohemia, by Prof. Fritsch.—Beats, the third sound of Tartini, and the differential resultant sounds of Helmholtz, by Dr Crotti.

No. 19, October 15.—New registering pluviometer, by S. Grimaldi —New apparatus with petroleum heating, by S Esser. —On a new variety (Rosterite) of Elban beryl, by Prof Grattarola

Kosmos, July 1880, contains a translation of Prof. Huxley's "The Coming of Age of the Origin of Species" (*vide* NATURE, vol xxii. p 1) —Dr Ernst Krause's sketch of the developmental history of the History of Development —Dr. H Muller, the importance of Alpine flowers in connection with the "flower theory"—H. Schneider, observations on some apes —Prof Dr Caspary, the conception of a soul and its significance in connection with modern psychology.—Short contributions and extracts from journals (among the short articles is one on the resemblance between flowers and fruit, by Hermann Muller, and on the occurrence of a five toed example of *Archibutio lagopus*, by W. von Reichenau)

August, 1880 —Dr Oscar Schmidt, the severance of species and natural selection.—Dr Ernst Krause, sketch of the developmental history of the History of Development, No 2 —Dr Herman Muller, on the development of the colours of flowers —Prof A H Sayce, on the history of writing (translation) —Short contributions and extracts from journals —Literature and critical notices.

Revue des Sciences Naturelles, September.—M Mathias Duval, on the development of the spermatozoa in the frog (Plates 3 and 4).—M Lavocat, on the construction of the extremities of the limbs —Dr A Godron, on the absence of a glume in the lateral spikelets of Lolium — M Leymerie, sketch of the Pyrenees of the Aude —Notices of French memoirs on zoology, botany, and geology —Bibliography and notice of the death of Dr. A. Godron

SOCIETIES AND ACADEMIES

LONDON

Chemical Society, November 4.—Prof H E. Roscoe in the chair.—The following papers were read —On the compounds of vanadium and sulphur, by E W. F Kay The author shows that the products obtained by Berzelius are oxy-compounds, that the substance obtained by Berzelius in the dry way is a true trisulphide of vanadium V_2S_3, the disulphide and pentasulphide have also been prepared and are described in the present paper.—On the atmospheric oxidation of phosphorus and some reactions of ozone and peroxide of hydrogen, by C. T Kingzett The author concludes that in the above oxidation both ozone and peroxide of hydrogen are formed, the former

passes on in the current of air, the latter remains in the water in which the phosphorus is oxidised. In several experiments the proportion of peroxide of hydrogen to the ozone formed was as *1 to 2*.—On the action of zinc ethyl on benzoylic cyanide, by E. Frankland and D. A. Louis. The product of this reaction, an amber-coloured jelly, was first decomposed and then extracted with alcohol, about 3 per cent. of a substance $C_{24}H_{18}NO_2$, named provisionally benzcyanidin, crystallising in colourless needles, was obtained. Besides this body an unstable substance was obtained which could not be purified, but which on oxidation with bichromate gave propiophenone $C_9H_{10}O$. —On the action of zinc-ethyl on cyanogen, by E. Frankland and C. C. Graham. The product of this reaction was a solid mass, which on heating to 120° yielded a colourless liquid which was propionitrile C_3H_5N., the other product of the reaction being zinc cyanide.—On bismuth and bismuth compounds, by M. M. P. Muir, G. B. Hoffmeister, and C. E. Robbs. The relative stabilities towards heat and reducing agents of the oxides, and towards heat of the hydrates are discussed, also the action of chlorine and bromine on the oxides. An attempt is made to give structural formulæ for these bodies, in which bismuth is trivalent.—On the colour properties and relations of the metals copper, nickel, cobalt, iron, manganese, and chromium, by T. Bayley. The author has carefully compared the colours of solutions of salts of the above metals and various mixtures thereof, and especially those mixtures which yield colourless or neutral grey solutions.—Action of diazo-naphthalin on salicylic acid, by Percy Frankland.—On the basic sulphates of iron, by Spencer Pickering.—Fourth report on researches in chemical dynamics, by C. R. A. Wright, E. H. Rennie, and A. E. Menke.—On some naphthalin derivatives, by C. E. Armstrong and N. C. Graham.—On acetylorthoamidobenzoic acid, by P. P. Bedson and A. J. King.

VIENNA

Imperial Academy of Sciences, October 21.—On the propagation of ball and cylinder waves of finite width of vibration, by Dr. Tumlirz.—On the law of convulsive action (continued), by Prof. Stricker.—On the blood vessels of the valves of the heart, by Dr. Langer.—On the question of arrangement in the pyridin and chinolin series, by Dr. Skraup.—Experiments on the magnetic behaviour of iron, by Herr Haubner.—On the relation of the daily and yearly variation of temperature to the sun spot period, by Herr Liznar.

PARIS

Academy of Sciences, November 2.—M. Edm. Becquerel in the chair.—The following papers were read:—New observations on the etiology and prevention of *charbon*, by M. Pasteur. He gives a letter written by Baron von Seebach (Saxon Minister in Paris) to M. Tissandier in 1865, stating facts which afford striking confirmation of M. Pasteur's views as to the causes of the disease.—On the heat of formation of ethers formed by hydracids, by M. Berthelot. In these experiments he used his calorimetric detonator.—Heat of formation of sulphide of carbon, by M. Berthelot. The combustion of liquid sulphide of carbon liberates +246·6 cal. (Favre and Silbermann obtained 258·5 cal., but they overlooked the formation of sulphuric acid). Sulphide of carbon is formed with absorption of heat from its solid elements, but there is probably liberation of heat from gaseous sulphur and carbon.—On volcanic thunderstorms, by M. Faye. In paroxysmal eruptions the enormous amount of steam ejected causes volcanic thunderstorms, which are quite distinct from ordinary thunderstorms, especially in the absence of gyratory movements, the complete immobility of the volcanic storm (which is confined to the column of ascending clouds), and the fact that no flashes occur without the presence of ashes. The phenomena are very much those of the Armstrong electric machine. Further, there is never any mention of hail, and M. Faye thinks it is probably never produced, as it is the product of vast gyratory movements not found in volcanic clouds. He suggests the desirability of studying directly the traces of electricity in the vapours rising from the crater of Vesuvius.—On photographs of nebulæ, by M. Janssen. The photography of a very bright nebula is now comparatively easy, if one content oneself with the most luminous part, but extremely difficult if a complete image be sought comparable to those given by our large instruments. The latter is what we especially require, with a view to studying the important questions of variations of nebular structure, and calls for many able workers, furnished with the best instruments. M. Janssen is preparing observations of the kind at Meudon.—Observations of planets and comets, at Marseilles Observatory, by M. Stephan.—On the winter egg of phylloxera, by M. Valery-Mayet. It seems certain that the hygrometric state of the air, generally very dry in Languedoc (where the author is), is the great obstacle to production of the winter egg. Whenever the sea-winds, which always blow in autumn, bring that region to the conditions of the climate in the west, the egg is produced.—Elements of the orbit of the new planet (217) discovered by M. Coggia.—On the resolution of algebraic equations; examination of the method of Lagrange, by M. West.—On linear differential equations with rational coefficients, the solution of which depends on the quadrature of a rational function of the independent variable, and of an irrational algebraic product, by M. Dillner.—On a property of uniform functions of a variable connected by an algebraic relation, by M. Picard.—On the application of the photophone to study of the sounds which occur on the sun's surface, by Prof. Bell. This was suggested by Mr. Bell in visiting the observatory at Meudon. M. Janssen put all the instruments at his disposal, and an opportunity was taken to explore a solar image 0·65 m. in diameter with the selenium cylinder. The phenomena were not sufficiently marked to justify one in affirming success, but Mr. Bell is hopeful of succeeding. M. Janssen has suggested the method of passing rapidly before an objective which should give conjugate images on the selenium apparatus, a series of solar photographs of one spot taken at intervals sufficient to show notable variations in the constitution of the spot. This is to be tried.—On the oxidation of mannite, by M. Pabst.—On the ferments of albuminoid matters, by M. Duclaux. There are certainly over a hundred species, and of these he only knows twenty at present (the physiological conditions, *i.e.* of their existence). Previous classifications prove useless. He gives some general *traits*. *Inter alia*, in milk the ferments change the caseine into soluble albumen, but while the aerobian-ferments do this in a slow and regular way, the anaerobians do it with liberation of carbonic acid and hydrogen, part of which becomes sulphuretted hydrogen or even phosphides of hydrogen. In cheese-making the predominance of the aerobians has been unconsciously favoured. All the ferments studied are found in full activity in the stomach. They secrete soluble ferments, which are added to those of the organism.—Inoculation of symptomatic *charbon* by intravenous injection, and immunity conferred on the calf, the sheep, and the goat by this process, by MM. Arloing, Cornevin, and Thoma.

THE FUTURE OF POLAR RESEARCH

WE have had quite a flood of Arctic news during the last few weeks, and the question as to the direction to be taken by future Polar research is attracting attention in various quarters. Evidently those interested in this department of exploration are thinking that "something ought to be done"; but as to what that something should be, there is likely to be difference of opinion It is unfortunate that the United States expedition sent out at the instigation of Capt. Howgate to found a Polar colony at Lady Franklin Sound, had to turn back through some defect in the engines of the *Gulnare*. Had this ship been successful in reaching the proposed ground of the expedition's work it would no doubt have given an impetus to the scheme of Polar research which has gained the approval of the Arctic authorities of nearly all nations except our own On the other side of the American continent no news has been received from Mr Gordon Bennett's expedition in the *Jeannette* of later date than August, 1879, when that vessel was off Cape Serdze Kamen, all well, and on her way to Wrangel Land All the sea within Behring Strait, both on the American and Asiatic side, was searched this summer by the *Corwyn*, but no trace of the *Jeannette* was found. The conclusion from this that the expedition has come to grief, we have already pointed out is too hasty Everything was in her favour when off the coasts of Kamtchatka last year, and if she had fair sea-way there can be no doubt that the expedition would take advantage of it, and push on as far northwards as was safe. We should not be surprised if a year hence the *Jeannette* might emerge by Behring Strait or by Novaya Zemlya with news of equal importance to that brought back by the *Tegetthoff* years ago.

But perhaps the most generally interesting expedition on the part of the Americans is that which returned some weeks ago from searching for further relics of the crews of the *Erebus* and *Terror* With the details of this expedition our readers are already familiar. So far as further information concerning the fate of the Franklin expedition is concerned, the results have not been of much importance, though it would seem that the scientific results are of some value. What precisely these are remains to be seen. Had the handsome volume recently published by the U.S. Government under the able editorship of Prof Nourse, containing the narrative of Capt C F. Hall's second expedition, been issued before Lieut Schwatka set out two years ago, we doubt if he would have thought it necessary to go over the same ground again.[1] Hall's devotion to the memory of Franklin is well known, and his enthusiasm for Arctic exploration was almost a religion; his *Polaris* expedition will never be forgotten In order to obtain certain news of the fate of Capt. Crozier and the 105 men who, in April, 1848, abandoned the *Erebus* and *Terror*, Hall lived with the Eskimo in the neighbourhood of Repulse Bay and King William Land for five years, 1864–69. He, like Barry, also had heard of records possessed by the Eskimo, and to obtain these records he submitted to become an Eskimo himself for all these years. With infinite tact and patience he carried out the object of his expedition, succeeded in visiting the scene of the memorable disaster, saw many signs of the presence of white men, obtained many relics, heard many stories from eye-witnesses of the sufferings of Crozier and his men when trying to make their way to the Fish River, but obtained not a shred of any kind of record Among the things abandoned by the men in their last despairing efforts to reach a white settlement were certainly some books, but whether written or printed could not be ascertained. The poor Eskimo had no use for such strange things, and gave them to the children to play with, and long before Hall's visit all trace of them had vanished. Indeed the information he obtained was of pretty much the same character as that just brought back by the expedition under Lieut Schwatka The stories told to Hall by the Eskimo as to the wanderings and sufferings of the white men are interesting, though sad Apart from the immediate object of his expedition, Hall's long residence with the Eskimo, with whom he lived as one of themselves, yielded results of great interest He lived in their igloos, ate their food, wore their clothing, shared their joys and sorrows, joined in their feasts, their dances, and their hunts; in short, saw more of Eskimo life than probably any one has done before or since. The details given in his journals are a contribution of great value to a knowledge of the Eskimo, and the self-denial of the high-minded and sterlingly honest man in submitting to this kind of life for so many years, for so noble a purpose, raises him to the rank of a hero The volume edited by Prof. Nourse, with its many illustrations and handsome get-up, might well put our own Government to shame Prof. Nourse has done his part of editor admirably, and his volume will be of permanent value So successful has the work been that we believe a second edition has been issued As the work is only recently published, it may fairly be recognised as a contribution to a knowledge of the Arctic situation.

This is a good summer's work for America On the opposite side of the Pole some good work has also been done The Dutch in their tiny vessel the *Willem Barents* have done some good dredging in the sea between Spitzbergen and Novaya Zemlya, while Mr Leigh Smith has added greatly to his fame as an Arctic yachtsman by his work in Franz-Josef Land. He has as we have already told, greatly extended the known area of this archipelago, and shown fair grounds for believing that it extends polewards for a considerable distance He has proved, as was done last year also, that this Arctic land is by no means difficult to reach in an average year, and this has an important bearing on Arctic research. Last week we gave a few details of what had been done along the Murmanian coast and the White Sea by the Russian party under Prof. Wagner and we know that Baron Nordenskjold is spending the winter in St. Petersburg preparatory to undertaking his expedition next year to the New Siberian Islands.

All this is encouraging, though it would be still more so were these various efforts undertaken on some well-concerted plan. Already has the Geographical Society been asked to lend its influence to an expedition which we cannot but regard as an anachronism. We hear

[1] "Narrative of the Second Arctic Expedition made by Charles F. Hall." Edited under the orders of the Hon Secretary of the Navy, by Prof. J E Nourse, U S N (Washington Government Printing Office.)

much talk of the traditions of the English navy and the duty of England to be the first to reach the Pole. We fear the so-called traditions of the English navy must be made to conform to the requirements of modern science if she is to do any useful work in Polar discovery, just as they have been compelled to do in order that our navy may be able to keep abreast of the fighting power of other nations. To squander 30,000*l* in one huge attempt to reach the Pole would be as mad as for a merchant to embark all his capital in one hazardous undertaking Polar research and Polar expeditions are not incompatible, but as Dr Neumayer showed in an admirable address at the Danzig meeting of the German Association, the former must be subordinated to and guided by the results of the latter. Preparations are being made by nearly all the countries of Europe and by America for a regular Arctic siege, to begin in 1882, the days of Arctic campaigns are past We have reached the precincts of the citadel itself, and now the sappers and miners must begin their slow but sure work, to be capped at the proper time by a grand assault Germany, Austria, Norway, Sweden, Russia, Denmark, the United States, and we believe Canada are all to take part in this great work by establishing observing stations at suitable points all round the Polar area; while Italy is to send out next year a scientifically equipped expedition to the Antarctic region, our knowledge of which is meagre and uncertain This last will really be an observing as well as an exploring expedition, preparatory to the establishment of an Antarctic station. Should our Geographical Society take any steps in the direction of Arctic work, we trust it will not be to encourage the foolish venture for which the country has been canvassed for subscriptions for years. We hope that Society will see that as a scientific body, its duty is to encourage a scientific method of work, and if it appeals to Government at all, let it be to urge it, for the honour of our country, to join in the concert of both hemispheres for the siege of the Polar citadel We have already pointed out on several occasions the vast gains to science that might be expected from the work of a series of Polar observatories established on the plans so ably sketched by Lieut Weyprecht. As Dr Neumayer said in the address alluded to, men of science do not demand practical or so-called utilitarian reasons before giving their adhesion to any new work, it is enough if it can be shown that such work will conduce to the advancement of knowledge. And that Weyprecht's scheme of Polar observatories, of which so many Governments approve, will lead to vast additions being made to scientific knowledge, no man of science needs to be told. In meteorology, terrestrial magnetism, biology, geology, and glacial physics, the gains would be immense, and the history of science has taught us over and over again that the surest path to practical and beneficent results is through the gate of pure scientific research. Every day is the science of meteorology becoming more and more important, but until we are thoroughly acquainted with the meteorology of the Arctic regions, that most practical of sciences is deprived of what is perhaps its most important factor. But one element of the international scheme is that of Polar exploration, conducted, however, on scientific method, and along lines indicated by a scientific knowledge of Arctic conditions such as can only be obtained by permanent observing stations What success is likely to result from Arctic work carried out on such a method was triumphantly shown by Baron Nordenskjöld when he sailed along the North-East Passage in the *Vega*. Why then should not England set up a station on Franz-Josef Land, and another say on some part of the American coast? Let the station be provided with the means of carrying out exploration in whatever direction and by whatever means the results of continued observation may indicate —as far as the Pole itself, if need be. Unless we are blind to the teachings of science and the lessons of our last expensive expedition, it is clear that this is the only sure method of reaching the Pole, if it be thought absolutely necessary for the credit of England that she should be the first to get at a point which it will take considerable trouble to spot If our Government be well advised, we are sure they will never give the public funds either for any great national expedition modelled on the lines of the past, nor to any private chimera got up for the glory of one man and the gratification of balloonists We do not see how, without national discredit, England can keep aloof from an international scheme, the scientific and practical results of which will be of world-wide importance, and it is the duty of the Geographical Society to lend all the weight of its influence to induce the English Government to take up its share in the new and only effectual method of Polar exploration

THE SANITARY ASSURANCE ASSOCIATION

IT is admitted on all hands that a vast amount of unnecessary disease, suffering, and death is caused by defective sanitary arrangements, especially as regards drainage A few years ago, so long as there was no foul smell, and all the pipes were "properly trapped," everybody was satisfied, but properly trapped usually meant improperly ventilated, or not ventilated at all, and we know now that foul gases will pass steadily, continuously, and certainly through water in traps.

Clinical observation having demonstrated the fact that sewer air produced diseases, the prevention of the entering of such foul air into houses became of paramount importance; and the matter being thus brought to so narrow an issue, the application of well-known physical laws was all that was required; it was necessary to study the circumstances under which foul air was produced, to prevent its production as far as possible, and to take such precautions that foul air, even if formed, could not accumulate and could not find its way into houses

Science has done much, both directly and indirectly, towards the prolongation of life; and certainly not the least important of the results of the application of scientific methods to this end in recent years has been the discovery of the ways in which a house can be made practically sewer-air proof The laws of health are being studied more and more every day, and will soon be taught as a matter of course in all our schools; they are already recognised as a special subject of study at the Universities. People are beginning to perceive that their health is a matter which is very largely indeed in their own hands, and are beginning to turn this knowledge to account in the matter of house sanitation. At the first

meeting of the Sanitary Assurance Association, presided over by Sir Joseph Fayrer, eminent members of the two professions which must always occupy the most reponsible position in connection with household sanitary matters, the professions of medicine and architecture, bore ample evidence to this fact, and at the same time to the necessity for some organisation by which the benefit of the best advice on such matters may be brought within the reach of the many. At this meeting Mr. Mark H. Judge pointed out that the Association "was the outcome of efforts which had been going on for some months to bring together architects and medical men in connection with the important question of house sanitation," and the names already identified with the Association are a sufficient guarantee that it will be both practical and permanent in its character. Sir Joseph Fayrer rightly stated in his opening address that "there is a terrible absence of all supervision of sanitary arrangements and drainage in many of the houses of the metropolis," and that although the richer classes of the population are able to get that sanitary advice which will enable them to make their houses wholesome, "there is an enormous population left, as regards which such a thing is hardly possible." Saying that he believed the idea was beginning to grow that "sanitation generally will increase the value of life," he continued, "over and over again it has come to my knowledge, and even occurred under my own observation, that families, children and servants, have suffered by the defects of drainage or sewer air—that great enemy to public health. I would venture to offer no opinion as to the nature of the diseases that proceed from sewer air, nor even enter into any discussion on the precise character of the air—the nature of the germs and the character of the poisons that it communicates; but that it does destroy health and induce disease is beyond a doubt. That it is greatly under the control of sanitary law is equally certain, and there are men now who have so studied and comprehended the nature of those laws, that they are able, practically as well as theoretically, to give that assistance and that advice which should render those conditions almost innocuous—in fact it should prevent them altogether."

Dr. Andrew Clark, after stating that he considered the Association "one of the most pressing needs of the present time," added:—"Furthermore I am convinced that if the Association can secure and retain the services of men with the scientific and practical knowledge possessed by Prof. Corfield, and will hold itself free from undertaking the execution of the works which it may suggest, superintend, and from time to time certify as sufficient, it will do important service to the public, and confer much and just credit upon all concerned."

Mr. Edwin Chadwick, the veteran sanitarian, said that "he constantly advised people, from his knowledge, 'Do not take that house unless you have it examined first If the drains are out of order do not take it till they are put right. That was exactly what this Association had to supply."

We are happy to state that the formation of the Association was decided upon, and the following gentlemen were appointed a committee to organise it:—George Aitchison, F.R.I.B.A.; Prof. W. H. Corfield, M.A., M.D; Prof F de Chaumont, M D, F.R.S., Mark H Judge, Prof T. Hayter Lewis, F S A, H Rutherford Barrister-at-Law, with Prof Corfield as Chief Sanitary Officer, and Mr Judge as Surveyor.

It is surely as necessary to be assured against preventible diseases as it is to be assured against fire, and we see from the preliminary prospectus issued that it is intended to give persons who place their houses on the Assurance Register certificates that their houses are in a satisfactory sanitary condition, and to endorse such certificates from time to time; this latter point is of great importance, as it is only by regular inspection at stated intervals that it is possible to ascertain that all continues to work satisfactorily.

A very important feature is also the proposal to examine and report on the plans of new houses, for there is at present absolutely no control exerted over the sanitary arrangements of new houses in the metropolis

We have given such prominence to this matter because we believe that the Association will supply a widely-felt want, and will do good not only directly but indirectly too; thus wise builders will take care to have their houses supervised and certified, and will reap their reward in increased facilities for letting, architects will submit their plans for criticism and suggestion; and so the public will in many ways reap a lasting benefit. In this country few new things succeed unless public opinion is ripe for them. We are slow to adopt new ideas; but we have now learnt the importance of preventing disease, we believe that much of our health depends on the perfection of the drainage arrangements of our houses, and we are ready to place them in the hands of an association in which we can have confidence

HINCKS'S "BRITISH MARINE POLYZOA"

A History of the British Marine Polyzoa. By Thomas Hincks, B A, F R S (London J. Van Voorst, 1880)

THE value to science of Mr Van Voorst's splendid series of volumes descriptive of the Natural History of the British Islands is scarcely to be overrated. The monographs are all the work of most eminent naturalists, in whom perfect confidence may be placed, and they are sumptuously printed and illustrated with abundance of excellent plates and woodcuts. The thanks of naturalists generally are certainly due to Mr Van Voorst. The present work is fully equal in merit to its predecessors, it consists of two volumes—one of 600 pages of text, the other containing eighty-three lithographic plates. Mr. Hincks, whose industry is indefatigable, has already contributed to Mr Van Voorst's series the well-known excellent monograph on the Hydroid Zoophytes. The labour involved in the production of a monograph such as that now under consideration is very great. All the 235 species occurring on the British coast are figured, with one or two exceptions in cases where specimens do not exist for the purpose. All the figures have been drawn by the author himself and beautifully lithographed by Mr. Hollick. Further figures are added taken from various monographs where such are necessary for the elucidation of the subject.

The work commences with an introduction, in which the author, after expressing his obligation to Mr Busk,

Mr. Norman, Mr. Peach, Dr. McIntosh, Prof. Ray Lankester, and others who have given him valuable aid in his work, gives an account of the structure of the Polyzoa generally, with some details concerning their development, life-history, and distribution. Several pages are devoted to the question of the name of the class concerning which it seems almost hopeless that any unanimity amongst naturalists will be attained. The author adopts J. V. Thompson's term Polyzoa on the ground of priority, and we hope it may prevail in this country, although it is scarcely probable that Continental zoologists will, as the author trusts, "reconsider the grounds on which they have hitherto given their adhesion to Ehrenberg," and give up the term Bryozoa (*Moosthierchen*).

Several pages are devoted to the question of the nature of the "brown bodies," which the author, following Prof. F. A. Smith and from his own extended observations, formerly considered to be essentially concerned in the production of new polypides by germination. He now admits that the evidence at present tallies better with the residuary theory of Nitsche and Joliet, who, as is well known, regard the bodies as merely remains of decayed polypides, but thinks that further investigation on the matter is yet required. An interesting series of woodcuts are given illustrating, as shown in a series of different species, the development of the avicularium from the first rudimentary stages, hardly distinguishable from the ordinary zoœcium, up to its most highly specialised bird's head-like form. Most readers are familiar with Mr. Darwin's account of his experiments on the avicularia of Polyozoa made during the voyage of the *Beagle* and published in his Journal. The author after citing these, and those of Mr. Busk and others, expresses himself as inclined to regard the avicularia as "charged with an offensive rather than alimentary function," believing that their vigorous movements and the snapping of their formidable jaws may drive away loafing annelids and other enemies.

Some short account of the embryonic development of the Polyozoa is given, and is illustrated by a coloured plate of larvæ taken from the splendid monograph on the subject by Dr. J. Barrois of Lille. In the matter of classification the author follows Ray Lankester as far as the main sub-classes are concerned, dividing the class according to the characters of the lophophore into the Holobranchiata, or those which have the tentacles in a continuous series, and the Pterobranchiata, in which the lophopore is broken into two distinct arms like those of Brachiopods. The Pterobranchiata include only a single genus, the remarkable Rhabdopleura of Allman. The Holobranchiata are divided, after Nitsche, into the Ectoprocta, in which the anal orifice lies without the lophophore, and the Entoprocta, in which the orifice lies within it. The latter group includes the genera Pedicellina and Loxosoma only, whilst the main mass of the existing Polyzoa come under the Ectoprocta, the marine forms of which form a single order, Gymnolæmata of Allman, which order is divided by the author according to Mr. Busk's well-known system into the sub-orders Cheilostomata, Cyclostomata, and Ctenostomata. The generic terms adopted in the work are however in many instances different from those employed by Mr. Busk and other former authors, and many familiar species have changed their names, so that the student is somewhat confused. Thus the species hitherto ranged under the genus Leptalia are separated into sections and placed under the author's three genera, Mastigophora, Schizoporella, Schizotheca, and other genera.

As before stated, the number of British species of marine Polyzoa described in the work is 235. Of these 69 have as yet not been found elsewhere, but as the author adds, no inference as to their range can be drawn from this negative fact. For 28 species Shetland is the only British locality, 8 of these not being found elsewhere, whilst the remainder are Arctic forms, with the exception of two, one of which, *Cellaria johnsoni*, ranges as far south as Madeira, and is abundant in the Mediterranean. Some of the British species have an extraordinarily wide range. Thus *Cellaria fistulosa* occurs in the Mediterranean at Madeira, in South Africa, in Scandinavia and North America, in the Indian Ocean, and in Australia and New Zealand. And there are several similar instances of almost world-wide distribution, the species not being deep-sea forms, but such as flourish between tide-marks and in shallow water, though also found at greater depths. The author suggests as a possible explanation of the wideness of range of such species, in addition to migration along coast lines and in profound depths, the agency of currents, floating timber, and ships. There is a very close resemblance between the Polyzoan fauna of the south-west coasts of France and our own, whilst a small group of Polyzoa is common to our shores and those of South Africa, but these are also Mediterranean. The author expects that a flood of light will be thrown on the subject of the distribution of the Polyzoa by the results of the *Challenger* Expedition, when published. It is obvious that in treating of any branch of the marine fauna of a restricted area, such as the British Isles, it will be necessary to make some restriction as to depth in considering questions of distribution. Once the abyssal fauna is reached by the dredge the animals obtained have no longer any special connection with the shores off which they are obtained, but belong to the ocean bottom and are mostly cosmopolitan, or rather Oceanopolitan.

The cordial thanks of zoologists are certainly due to Mr. Hincks for having produced this most useful work. It will be valuable not only to the professed naturalist, but also an entertaining addition to the sea-side libraries of those who work occasionally with the microscope for recreation.

OUR BOOK SHELF

A Popular History of Science. By Rob. Routledge, B.Sc. (London: George Routledge and Sons, 1881.)

In looking through many of the works on popular science one is inclined to exclaim, "Oh, monstrous! but one halfpennyworth of bread to this intolerable deal of sack." Mr. Routledge's recent volume is fortunately an exception to this rule, for in it we find a clear and concise statement of the development of the main branches of physical science given in a readable form with such an amount of biographical notices as to impart a human interest to the tale. Extracts, too, from the writings of the great workers in science have been judiciously interspersed throughout the text, thus bringing the student into direct communication with the master mind. Numerous illus-

trations accompany the description; some of these are original, and others taken from the French, and none the worse for that. Most of them are well executed, but intimate friends might possibly find some fault with the likenesses of living men of science. Of course it is an easy as it would be a thankless task to point out sins of omission, and perhaps also of commission, in a book like the one under notice. Such works must not be looked upon with the eye of microscopic criticism. If the general direction which the author takes is the right one, if he does not make his task easy by glossing over all the points of difficulty, but puts his case clearly and fairly forward, he may well be excused if he omits matters which one or other of his readers may deem necessary These conditions Mr. Routledge, as it seems to us, has satisfactorily fulfilled. We can therefore cordially recommend this "Popular History of Science," believing that it will exert a healthy influence on all who read it, and may be a powerful means of spreading the love of science amongst the rising generation. H E. R.

Class-Book of Elementary Mechanics, adapted to the Requirements of the New Code. Part I *Matter*. By Wm. Hewitt, B Sc, Science Demonstrator for the Liverpool School Board. (London George Philip and Son, 1880)

MR. HEWITT has probably had a better chance than any other teacher of knowing by experience the working of the meagre science-subjects of the new educational code The defects of that code, and particularly of its directions as to the subject of mechanics, are very great, nevertheless the little book which Mr Hewitt has produced shows how, in spite of the disadvantageous system under which he works, a really good teacher will succeed in working up the subject for his pupils. We have seldom met with a *really* elementary book which at once combined to so great a degree simplicity of language, accuracy of description, and sound science Mr. Hewitt states as his experience that the main difficulty has hitherto been to get the children to express in anything like precise language the ideas suggested to their minds by the simple experiments shown them. He therefore intended this little work to serve as a lesson-book to be read by the pupils in the intervals between the experimental lessons This first part covers the ground prescribed by Schedule IV for the first stage. A second part, dealing with "Force," is in preparation, and will embrace the subjects of the second and third stages We hope Mr. Hewitt's second part will prove as satisfactory as is his first instalment. His aims are limited, indeed, by the requirements of the Code, but within those narrow limits his success is great.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.*]

[*The Editor urgently requests correspondents to keep their letters as short as possible. The pressure on his space is so great that it is impossible otherwise to ensure the appearance even of communications containing interesting and novel facts.*]

Sir Wyville Thomson and Natural Selection

I HAVE at least great reason to be thankful that my stupidity has not prevented me from thoroughly enjoying the teachings of Mr. Darwin and Mr Wallace, which I confess to having regarded as chiefly masterly and charming "studies in variation," for the last twenty years.

The title of the epoch marking book which came of age last month was, however, "The Origin of Species by Means of Natural Selection." Mr. Darwin, as I am well aware, has put forward this mode of the origin of species as a part only of a hypothesis which is universally looked upon as a supreme effort of genius.

It seemed to me, rightly or wrongly, that the fauna of the enormous area forming the abyssal region existed under conditions which held out the hope that it might throw some light upon a question which appears to underlie the whole matter, and which is still unanswered Are physiological species the result of the gradual modification of pre-existing species by natural selection, *or by any similar process*, or are they due to the action of a law as yet utterly unknown, by which the long chain of organisms rolls off in a series of definite links?

I fear I scarcely follow Mr Darwin's illustration If one were to pay his first visit to a breeder's, and be shown a flock of Leicesters, never having seen or heard of a sheep before, he would see nothing but a flock of sheep, and would certainly, without justly incurring the contumely of the breeder, be entitled to set them down merely as a group of animals of the same *species*, that is to say, animals fertile with one another and producing fertile progeny. He would judge so from their common resemblance, and without previous observation or information I do not see how he could know more about them But give him an opportunity of comparing the results of breeding throughout a long period of time, or of observing the process of breeding over half the world, which comes to much the same thing, the breeder might then have cause to rail if he had not picked up the stages of the process.

The close examination of the newer tertiaries and the careful analysis of the fauna of the deep sea seem to me fairly to represent these two methods, both of these promise to yield a mass of information in regard to the course of evolution, but as to the *mode* of the origin of species both seem as yet equally silent

I will ask you in a week or two for space for a short paper on "The Abyssal Fauna in Relation to the Origin of Species"

C. WYVILLE THOMSON

Rapidity of Growth in Corals

THROUGH the kindness of M. Parrayon, captain of the French man-of war *Dayot*, I have received a large coral of the fungia tribe, which was yesterday found attached to the bottom of his ship as the copper was being cleaned by native divers The following is the history of the occurrence. The *Dayot* entered the tropical waters of the South Pacific about seven months ago, coming directly from the coast of Chile. She visited some of the islands, but made no long stay in harbour until she reached Mauga Reva (Gambia Islands), where she remained for two months in the still waters of a coral basin. On entering the basin she touched the reef slightly, and without sustaining any damage. From Mauga Reva she sailed to Tahiti, where she now lies

Several specimens of living coral were found attached to the copper sheathing, that which I have received being the largest It is discoidal in shape, with its upper and under surfaces respectively convex and concave, and near the centre of the under surface there is a scar, where the pedicle by which it was attached to the copper sheathing was broken through. The disk measures 9 inches in diameter, and the weight of the specimen (now half dry) is 2 lb. 14 oz On examining the under surface another disk $3\frac{1}{4}$ inches in diameter is seen partly imbedded in the more recent coral growth Of this old disk about one-sixth part is dead and uncovered by new coral, and is stained of a deep blue colour from contact with the copper, while the outline of the rest of this old disk is plainly discernible, although partially covered in by plates of new coral

My impression is that on touching the reef at Mauga Reva nine weeks ago a young fungia was jammed against the copper, became attached, and subsequently grew to its present dimensions.

The case affords an interesting illustration of the rapidity of the growth of coral in these waters. R. W COPPINGER

Tahiti, August 13

Geological Climates

SINCE contributing the chapter in the history of the Coniferæ upon which Prof. Haughton remarks, I have seen *Araucaria Cunninghami* growing in gardens round Funchal, and my belief in the specific identity of the Bournemouth Eocene plant is further strengthened; yet still, as only foliage is known in the fossil, I should hardly be prepared to contest upon that alone a question of climate, however minute the resemblance. But even with the most undisputed identity there are so many possibilities

of error in arguing from a single species, that little importance should be attached to conclusions drawn from it.

Assuming them however to be specifically identical, as I myself believe them to be, and to have required precisely the same temperature, I think Prof. Haughton's case is not quite so strong as he believes. The present mean winter temperature of Bournemouth in lat 50° 43′ is 37° 4′, but the physical surroundings of Bournemouth are not now such as conduce to luxuriant forest growth, even if its temperature sufficed, and the conditions there in the Eocene time more probably assimilated to those of the south-west coasts of Ireland at the present day.

Now the mean of the coldest month at Valentia, lat 51° 44′, is 44°, and it may be fairly assumed that if Valentia were a degree farther south, corresponding to Bournemouth, the temperature would be one degree higher, and if sheltered by mountains from all the northerly winds as Glengariff is, the mean might possibly be raised to 46°. Thus but 11° are required to reach the minimum of 57° supposed to be required by his Araucaria Again, although the Moreton Bay Pine does not appear to support a less mean annual temperature than 67° to 70° between the Clarence and the Bellingen, which are its southern limits in Australia, it flourishes and ripens seeds in Madeira in a mean of 64° 96′, and although I have only noticed it in two gardens near the sea-level, I think it has only been excluded from others higher up the mountains in favour of the far more striking *Araucaria excelsa* Moreover from its present restricted area it appears to be a declining type, which may, when more widely distributed, and possibly in presence of fewer competing species in remote Eocene time, have sustained greater extremes of climate

Taking the species, however, as it exists, and apart from any such possibilities, uniformitarians have, it seems to me, but to account for an increase of 14° to 15°, that is if Bournemouth were near its northern limit, as seems probable from its having grown at or near the sea-level.

Supposing, as all evidence tends to prove, that Northern Europe and America were connected by continuous land in Eocene time, would not the mere fact of shutting off the Arctic Seas cause a general and perhaps sufficient rise of temperature? In N. lat. 70° Prince Albert Land has a mean of only 5° Fahr, and Lapland one of 32°, a difference of no less than 27°, caused solely by the presence of an Arctic ice-laden current. The general cooling effect of incessant oceanic circulation between the North Pole and the Tropics is, I think, scarcely taken into sufficient account, and although it may be contended that conversely the northerly flow of the Gulf Stream mitigates climate, I think that its action in Europe is chiefly in fending off the ice-laden currents from our coasts, the limit of trees penetrating quite as far north in Siberia away from the coast as at the North Cape, where they are under its influence J. STARKIE GARDNER

Order Zeuglodontia, Owen

IN August 1848 H M.S. *Dædalus* encountered off St Helena a marine animal, of which a representation appeared in the *Illustrated News* of the latter part of that year. It is thirty-two years since I saw this figure, but I recollect that it was one of a blunt-nosed animal with a neck carried about four feet above the water, which was so long as to present the appearance of a serpent, and I remember that Prof Owen, in combating at the time the idea that this was a sea-serpent, pointed out that the position of the gape in relation to the eye, as shown in the figure in the *Illustrated News*, was that of a mammal, and not that of a reptile, in consequence of which he argued that the animal seen was probably only a leonine seal, whose track through the water gave an illusory impression of great length This idea, however, seemed to me untenable in the face of the representation in the *Illustrated News*, but it was obvious that to afford the buoyancy necessary for the support above the water of so long a neck (estimated on that occasion as sixty feet, though only the part near the head was actually out of the water), the submerged portion of the animal could not have had the shape of a serpent.

Two or three years after this, on reading the description of *Zeuglodon cetoides*, from the Tertiary (probably Upper Eocene) formations of Alabama, it struck me that the animal seen from the *Dædalus* may have been a descendant of the order to which *Zeuglodon* belonged; and I have ever since watched with interest for reports of the "great sea-serpent."

Three years ago the following appeared in the newspapers.—

"Borough of Liverpool, in the County Palatine of Lancaster to wit.

"We the undersigned, captain, officers, and crew of the barque *Pauline* (of London) of Liverpool, in the county of Lancaster, in the United Kingdom of Great Britain and Ireland, do solemnly and sincerely declare that on July 8, 1875, in lat. 5°3′ S., long 35° W, we observed three large sperm-whales, and one of them was gripped round the body with two turns of what appeared to be a huge serpent The head and tail appeared to have a length beyond the coils of about 30 feet, and its girth 8 or 9 feet. The serpent whirled its victim round and round for about fifteen minutes, and then suddenly dragged the whale to the bottom head first

"GEORGE DREVAR, *Master*
"HORATIO THOMPSON
"JOHN HENDERSON LANDELLS
"OWEN BAKER
"WILLIAM LEWARN

"Again, on July 13, a similar serpent was seen about 200 yards off, shooting itself along the surface, head and neck being out of the water several feet This was seen only by the captain and one ordinary seaman, whose signatures are affixed.

"GEORGE DREVAR, *Master*."

"A few moments after it was seen elevated some sixty feet perpendicularly in the air by the chief officer and the following able seamen, whose signatures are also affixed—

"HORATIO THOMPSON
"WILLIAM LEWARN

"And we make this solemn declaration, &c.

"Severally declared and subscribed at Liverpool aforesaid, the 10th day of January, 1877, before

"T S. RAFFLES, J.P. for Liverpool."

The locality here specified was about thirty miles off the northern coast of Brazil

In this account I thought that I recognised the grip of the whale by the long neck of the attacking animal, the appearance being confounded into the double coil of a serpent by the distance and motion of the objects; but in face of the general ridicule which has been attached to this subject, and being without any assurance that the declaration so purporting to be made was genuine, I did not venture to ventilate my long-cherished idea. A relative of mine, however, just returned from India, chancing to say that two of the officers of the steamer in which she went out had on the previous voyage witnessed an immense animal rear its neck thirty feet out of the water, and that a sketch of the object had been instantly made, and on reaching port sent to the *Graphic*, I obtained the number of that paper for July 19, 1879, and I inclose a tracing of the figures in it, which are accompanied by the following statement in the *Graphic* —

"The accompanying engraving is a *fac-simile* of a sketch sent to us by Capt. Davison, of the steamship *Kiushiu maru*, and is inserted as a specimen of the curious drawings which are frequently forwarded to us for insertion in the pages of this journal Capt. Davison's statement, which is countersigned by his chief officer, Mr. McKechnie, is as follows —'Saturday, April 5, at 11.15 a m, Cape Satano distant about nine miles, the chief officer and myself observed a whale jump clear out of the sea, about a quarter of a mile away. Shortly after it leaped out again, when I saw that there was something attached to it. Got glasses, and on the next leap distinctly saw something holding on to the belly of the whale The latter gave one more spring clear of the water, and myself and chief then observed what appeared to be a large creature of the snake species rear itself about thirty feet out of the water It appeared to be about the thickness of a junk's mast, and after standing about ten seconds in an erect position, it descended into the water, the upper end going first. With my glasses I made out the colour of the beast to resemble that of a pilot fish.'"

As I have not been able to find any description of the skeleton of the *Zeuglodon*, I venture to draw attention to the subject through your columns, in the hope that among your many readers in America this letter may attract the notice of some one who will tell us whether what is known of the osseous structure of *Zeuglodon cetoides* is or is not consistent with the representation in the *Graphic*. The remains of this cetacean, supposed to be extinct, indicate, according to Sir Charles Lyell, that it was at least seventy

feet in length,[1] while its great double-fanged but knife-edged molars show that it was carnivorous; and as we are not so far removed from the period of the Alabama Tertiaries as to render it improbable that members of what must once have been a great order of carnivorous cetacea, totally distinct from the orders of cetacea hitherto known as living, may still survive, I have braved the ridicule attaching to this subject so far as to invite attention to it

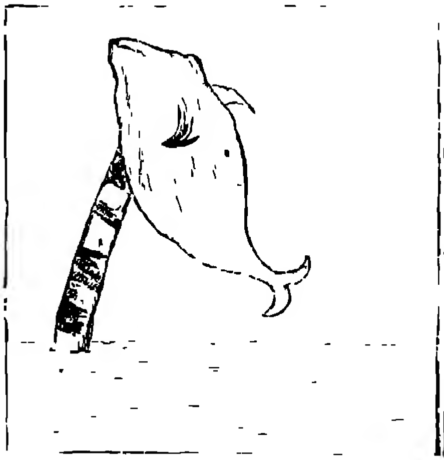
The second of the two figures in the *Graphic* shows the long-necked animal to possess the cetacean tail, and its head there seems to have been turned from the observer, so that the under-side of it only is presented. The first figure shows that the whale had been seized on its flank by the powerful bite of its aggressor, and that to escape from this it had thrown itself out of the water. Having succeeded in this object the second figure shows the aggressor rearing its head and neck out of the water to discover the direction which its prey had taken, in order that it might follow it up, and so far from the charge of curious drawing made by the editor of the *Graphic* being justified, the representation of the whale can be at once recognised as fairly correct, while that of the tail of the unknown animal (which probably prompted this charge), so far from being curious, forms an important piece of evidence as showing the animal in question to be cetacean.

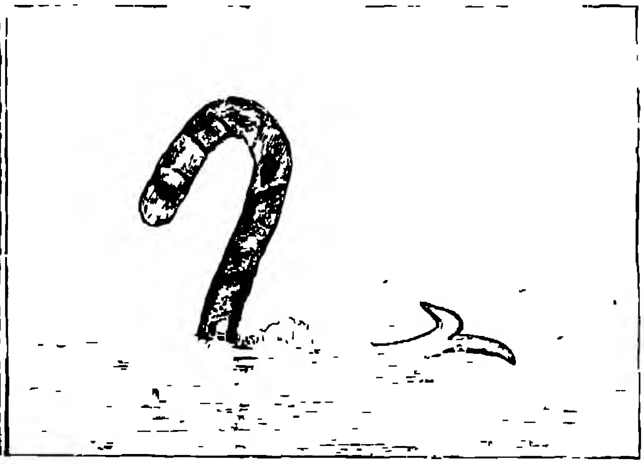
SEARLES V WOOD, Jun

Martlesham, near Woodbridge, September 27

P S —Since sending to you the above I have again seen my relative, and find that the cut in the *Graphic* of July 19, 1879, is not that of the instance observed from the steamer in which she came home, which was the *City of Washington*, but of a separate instance which occurred to another ship I have not been able yet to procure the *Graphic* containing the figure of the animal seen from the *City of Washington*, but she tells me that it was pasted up in the saloon, and represented only the head and long neck of the animal, which was raised to a great height out of the water, and near to the ship, and had been drawn for the *Graphic* by a lady passenger immediately after the occurrence These repeated and independent notices of the same long-necked animal are, however, the more confirmatory of its existence.

I find that Prof. Owen, in his article on Palæontology in the *Encyclopædia Britannica* (vol. xvii p 166), in giving a description of *Zeuglodon cetoides*, says that "the skull is very long and narrow *and the nostril single*," that Dr Harlan obtained the teeth on which, correcting Harlan's reptilian reference of them, he founded the order *Zeuglodontia*, from the Miocene of Malta, and that the teeth discovered by Grateloup in the Miocene beds of the Gironde and Herault, and ascribed by him also to a reptile under the name of *Squalodon*, are those of a smaller species of *Zeuglodon* The remains of *Squalodon*, along with those of the shark with huge teeth, *Carcharodon megalodon*, and of numerous cetaceans assigned to orders all still living, and of which some, such as *Delphinus*, belong to living genera, occur in the "Sables inférieurs" of Antwerp, which, though long called Miocene, are by M Vandenbroeck regarded as older Pliocene, and as the base of that series of deposits of which the





middle and upper divisions are respectively represented by the Coralline and Red Crags of England, and with these "Sables inférieurs" the so-called Miocene of Malta, in which *Zeuglodon* is associated with *Carcharodon*, is probably coeval. Dr. Gibbes (*Jour Acad. Nat. Sc.*, 2d. ser, vol. i. p 143), figures and describes teeth of the Antwerp species of *Carcharodon* from both the Eocene of South Carolina and the Miocene of Alabama These various references bring the *Zeuglodonts*, with their *Carcharodon* associates, down to a late geological period, during which they co-existed with Delphinian prey; and of this prey the whale in the woodcut (which looks like a *Grampus*) seems an example

It is most likely that Bishop Pontoppidan, a copy of the English (1755) edition of whose work I possess, concocted his two figures (one of which is that of a huge snake undulating on the waves, and the other that of a serpent-like animal with pectoral flappers or fins, resting almost on the surface of the sea, with head and tail erect out of the water like the letter U, and spouting water or steam from its mouth *in a single column*), from accounts given him by Norwegian seamen, some of whom had seen the animal in the position in which it was observed from the *Dædalus*, and others in that in which it is represented in the cut as seen from the *Kiushiu-maru*; for in the long narrative which he gives of the descriptions received from observers at numerous times, some of these agree with the one, and some with the other, though both of the Bishop's figures represent only preposterous conceptions of his own

[The animal seen from the *Osborne*, and figured in the *Graphic* of June 30, 1877, as the "Sea-serpent," is quite a different thing from the one in question, and may have been a *manatee*]

[1] He observes in the third edition of his "Manual of Elementary Geology" (1851), p. 208, that he visited the spot where a vertebral column of this length belonging to *Zeuglodon* had been dug up.

Temperature of the Breath

THE interesting observation made by Dr. Dudgeon (NATURE, vol xxii. p. 241, and vol. xxiii. p. 10) to the effect that breathing on the bulb of a thermometer through several folds of flannel or silk raises the temperature of the instrument several degrees above that of the mouth and body, is easily verified There is no doubt about the accuracy of the observation, but the explanation of it offered by Dr. Dudgeon is not satisfactory He supposes that the heightened temperature is due to the expired air being hotter—not cooler, as is usually believed—than the mouth and body A simple experiment sufficed to show that this view was untenable A clinical thermometer was inserted in the cavity of the mouth, and the stem grasped by the teeth in such a way that the bulb lay free in the oral cavity Inspiration was carried on by the nostrils, and expiration was effected by gently forcing the breath between the loosely-closed lips and the stem of the instrument. The bulb was thus placed in the centre of the stream of expired air and kept free from contact with the tongue and cheeks. Experimenting in this way, I found, at the end of five, and also of ten, minutes that the thermometer marked 97·2°—the temperature under the tongue at the time being 98·4°.

Had the breath been hotter than the mouth the instrument could not have failed to register a higher temperature than 98·4°, but being really cooler, the instrument, of course, recorded a lower temperature.

What is then the true explanation of the phenomenon observed by Dr. Dudgeon? I believe that it is simply an example of the conversion of latent into sensible heat by the rapid condensation of aqueous vapour The organic fabrics which compose our clothing are all more or less hygroscopic—that is to say, they have the capacity of imbibing aqueous vapour and condensing it into the solid and liquid forms. The expired breath is heavily charged with aqueous vapour, and aqueous vapour, at the moment of condensation, liberates an enormous amount of latent heat, which thus becomes sensible to the thermometer. In this particular watery vapour exceeds far away all other gases.

The following experiments were made with a view of testing the correctness of this view. Two strips of flannel were prepared, each six inches long and an inch and a quarter wide The first strip was rolled, without any preliminary preparation, round the bulb of a clinical thermometer. The bulb, thus enveloped, was inserted between the closed lips, and the expired air was forced through the porous material for a period of five minutes. The thermometer rose to 104°. The instrument was then allowed to cool, and, after having been re-set, was again inserted between the lips, and breathed through for a second period of five minutes. This time the temperature only rose to 101° The experiment was repeated a third time for a similar period, but this time the thermometer did not rise above 98·6.

These results tallied exactly with the requirements of the condensation hypothesis. During the first period the fresh dry flannel absorbed and condensed the watery vapour passing through it with such rapidity that the liberated sensible heat was sufficient to raise the mercury several degrees above the temperature of the mouth. In the second period of five minutes the hygroscopic activity of the flannel had been greatly reduced by the previous absorption of aqueous vapour, and the thermometer only rose slightly. In the third period saturation had been approached, and the breath passed through the flannel almost without depositing any of its moisture, and accordingly the thermometer only indicated a temperature slightly higher than that of the mouth

The second strip of flannel was subjected to a little preliminary preparation. In order to increase its hygroscopic activity it was thoroughly dried (superexsiccated) by holding it for a few minutes before the fire When it had cooled down to the temperature of the room it was wrapped round the bulb of the thermometer, and the experiment was proceeded with as before The result surprised me *In one minute* the mercury had risen not only to the top of the scale (112° F), but had filled the little bulb above it, that is to say, it had risen to at least 115° F When the instrument had cooled it was reset, and inserted again between the lips and breathed through for three minutes. At the end of this time the scale marked 106° F. After the instrument had been cooled and reset the experiment was repeated a third time, and the temperature only reached 102° after breathing through the envelope for four minutes. A fourth trial of four minutes only produced a record of 98 4° Here again the development of heat steadily declined as the flannel became less hygroscopic

It is probable that, with the superexsiccated flannel the first portions of aqueous vapour condensed at the beginning of the experiment pass at once from the gaseous into the solid form, and constitute that portion of water which is incorporated in intimate union with all organic tissues This accounts for the extreme rapidity of the development of heat at the commencement of the experiment. I found that even a single long expiration through the freshly-warmed flannel raised the mercury to 110° F.

Dr. Dudgeon's observation will not necessitate a revision of our conclusions respecting the temperature of the breath, but he has supplied us with an exceedingly elegant and easy way of demonstrating the liberation of sensible heat which takes place during the passage of water from the gaseous into the solid and liquid state.

WM. ROBERTS

Manchester, November 10

Height of the Aurora

IN NATURE, vol. xxii. p. 291, is inserted a letter of Mr. T. Rand Capron, on the determination of the height of auroræ, wherein I read: "It is unfortunate that simultaneous observations of the auroral corona are almost entirely wanting. I . . . would be glad if any particulars could now be furnished me."

Having treated the subject of the auroræ and their properties in an ample manner in my "Théorie cosmique de l'Aurore polaire" (*Memorie della Società degli Spettroscopisti Italiani*, 1878, vol vii), wherein I have adduced proofs of the thesis that *The corona is an optical illusion, due to the laws of celestial perspective*, I was astonished to find the alleged words used by so great an authority. That "simultaneous observations" of the auroral corona will be ever without any result, as far as its height above the earth is concerned, follows already from the known property, that the corona always shows itself in the direction of the *local* magnetic total force (given by the inclination needle).

Regretting that such a well-established fact seems not generally known, I take the liberty to refer Mr. Rand Capron to the chapter of my treatise, "Dans quelle Région de l'Atmosphère terrestre se trouvent les Rayons de l'Aurore polaire, et est-ce que la Couronne est une Chose réelle?" and will repeat here that very beautiful determinations of the height of streamers and beams were obtained by Prof. Heis and Dr. Flogel, and by Prof. Galle in Germany, showing a height of the phenomenon from 20 to 100 miles (of 15 in 1 degree). These results are published in the *Zeitschrift der oesterr Gesellsch f. Meteor* vii p 73.

I regret to have found no earlier opportunity of answering the request of Mr Rand Capron, but think that this letter may still have some interest, notwithstanding the valuable article by Mr. Plummer in NATURE, vol. xxii p 362

November 10

Fascination

As a contribution to this subject, at least of new material if of no decisive evidence in support of any existing theory, I offer the conclusions which Malachi Foot, Member of the College of Physicians and Surgeons, N Y, reached in 1807 relative to this matter A short memoir of his which I recently met was published in the *Medical Repository* for that year, entitled "An Examination of Dr. Hugh Williamson's Memoir on Fascination, to which is subjoined a New Theory of that Phenomenon," and is striking both in matter and conception

The author, after displaying some temper over Dr. Williamson's willingness to attribute the well-accredited effects of snake-charming to terror, producing in the victim a condition which he (Dr. Williamson) terms "dementation," and "wherein extreme fear stupefies the mind and deprives him of the understanding," produces his own explanation. Although he acknowledges the paralysing effects of fright, and instances quadrupeds falling lifeless from the effect of fear, deer stricken motionless by the light of a torch, &c., yet he inveighs against the false reasoning which discovers in these cases of arrested volition any analogy to the phenomena of so-called fascination. Our author, evidently of no superstitious habit, distinctly admits the fact that the snake repeatedly captures prey by a method seemingly so occult as to merit the characterisation of fascination, and develops his theory in the light of that very thought

He ascribes to the primary sensations of animals, in them unmodified by reflection as to their source or character, complete efficacy to awaken emotions of pleasure of an intensity to us quite incommensurate with the apparent causes which evoked them—emotions so powerful as to absorb all other secondary feeling, enfolding the animal in a delightful but numbing trance, whose stages advance from attention through ecstasy to anæsthesia. And he finds in the eye a sensory centre which most expansively responds to all outward stimuli. This much premised, he applies it to the case in hand. The snake, fixing its glittering eyes with hungry expectancy upon its victim, at the same time throws its body into graceful curves and raises its tail, undulating with a soft and inviting motion (Foot insists upon the almost invariable accompaniment of motion as auxiliary in attracting and pleasing the prey) The bird's eye, once caught, becomes ensnared in the endless succession of contortions, and it draws near, dominated by simple delight.

As Foot expresses it, "the pleasurable movements of the organs of vision stimulate to approach and excite an eager desire to embrace." *Reverie oculorum* ensues, and the bird flutters helpless to the ground. Foot speaks of having seen a cat succeed in similarly charming birds by wreathing the body and waving the tail, He might have confounded this with the

ordinary nervous concentration of attention common to the Felidæ before "pouncing." He speaks of larks being attracted in the South of France by means of an octagonal box holding a mirror mounted on a pivot which is turned by the wind. The reflected rays of sunlight dazzle and delight the birds, and they approach near enough to be caught by a spring net. The preliminary phase, that of attention, wherein curiosity perhaps predominates, is illustrated in the known trick of a fox amusing ducks by rolling itself down a bank, as also in the perilous interest excited in a loon by a handkerchief waved by an unseen hand. Many must have experienced, on looking over very high galleries upon floors beneath, or over sheer precipices, an almost uncontrollable impulse to throw themselves headlong down. Can this feeling be described as akin to "fascination"?

A. PERCY SMITH.—The little centipede is *Geophilus electricus*, well known to be occasionally luminous.

HOMAGE TO MR. DARWIN

ON Wednesday, November 3, a deputation from the Yorkshire Naturalists' Union waited upon Mr. Darwin at his residence, Down, Beckenham, Kent, for the purpose of presenting him with an address expressive of admiration for his long devotion to scientific research, and appreciation of the great and important results to which his investigations have led. Prof. Williamson, F.R.S., of the Owens College, Manchester, who is the president of the Union for the current year, was prevented from accompanying the deputation by the pressure of his professorial duties. The deputation arrived at Mr. Darwin's residence about 1 p.m., and was received in a most hearty manner by the great naturalist himself, Mrs. Darwin, and other members of the family. The members of the deputation were introduced individually to Mr. Darwin by Dr. Sorby, vice-president of the Union, and then the interesting ceremony of the presentation of the address was at once proceeded with. After a few words on the work of the Union by Dr. Sorby, the address was read by Mr. Thomas Hick, B.A., B.Sc., and formally presented to Mr. Darwin by Dr. Sorby. Replying to the address, Mr. Darwin assured the deputation of his deep sense of the honour the Yorkshire Naturalists' Union had conferred upon him on that occasion, and only regretted that he had not done something more deserving of such an honour. He had no idea previously that there was so strong a body of working naturalists in Yorkshire, but was pleased to learn that such was the fact, and to find from the *Transactions* that had been forwarded to him that they were doing useful work. Coming from such a body, the address was all the more gratifying to him, though he still feared he hardly merited the good things that had been said of him. The address which had been presented to him he and his family would for ever treasure and preserve, and he desired to express his warmest thanks, both to the deputation and those whom they represented, for it, and for the kind and considerate manner in which everything connected with it had been arranged. Subsequently the deputation were entertained at luncheon, and having spent a short time in familiar conversation with their hospitable host and his family, took their departure amid mutual expressions of kindness and regard.

The following is the text of the Address, which is dated August last:—

To Charles Darwin, LL.D., M.A., F.R.S., &c., &c.

SIR,—The Council and Members of the Yorkshire Naturalists' Union, all of whom, with scarcely an exception, are working students of one or more of the various branches of natural history, desire to express to you in a most respectful manner, and yet with the greatest cordiality, their admiration of your life-long devotion to original scientific research and their high appreciation of the almost unparalleled success of the investigations by which you have contributed so largely to the modern development and progress of biological science.

More especially do they desire to congratulate you on the fact that your great work on the Origin of Species will come of age at an early date, and that your life has been spared long enough to enable you to see the leading principles therein enunciated accepted by most of the eminent naturalists of the day. On the conspicuous merits of that and of your other published works they need not dwell, as those merits have been recognised and admitted even by those who have dissented most strongly from the conclusions at which you have arrived. They may nevertheless be permitted to remind you that your writings have been instrumental in giving an impetus to biological and palæontological inquiries which has no precedent in the history of science, except perhaps in that which followed the promulgation of the gravitation theory of Newton, and that which was due to the discovery of the circulation of the blood by Harvey.

One of the most important results of your long-continued labours, and one for which you will be remembered with honour and reverence as long as the human intellect exerts itself in the pursuit of natural knowledge, is the scientific basis you have given to the grand Doctrine of Evolution. Other naturalists, as you yourself have shown, had endeavoured to unravel the questions that had arisen respecting the origin, classification, and distribution of organic beings, and had even obtained faint glimpses of the transformation of specific forms. But it was left to you to show, almost to demonstration, that the variations which species of plants and animals exhibit, and in natural selection through the struggle for existence, we have causes at once natural, universal, and effective which of themselves are competent not only to explain the existence of the present races of living beings, but also to connect with them, and with one another, the long array of extinct forms with which the palæontologist has made us familiar.

Further, the Yorkshire Naturalists are anxious to place on record their firm conviction that in the care, the patience, and the scrupulous conscientiousness with which all your researches have been conducted, in the ingenuity of the experiments you have devised; and in the repeated verifications to which your results have been submitted by your own hands, you have furnished an example of the true method of biological inquiry that succeeding generations will deem it an honour to follow, and that cannot but lead to still further conquests in the domain of organic nature.

In presenting this small tribute of their high regard and esteem, the members of the Yorkshire Naturalists' Union cannot but hope and pray that many years of happiness and usefulness may yet remain to you, and that our Science and Literature may be still further enriched with the results of your researches.

and Eleven other representative Officials.

THE ATOMIC WEIGHT OF BERYLLIUM

FOR some time chemists have been doubtful what value to assign to the atomic weight of beryllium. Some years ago Prof. Emmerson Reynolds determined the specific heat of this metal to be 0·642; this number multiplied into 9·1 gave 5·8 as the atomic heat of beryllium, in other words it confirmed the generally accepted atomic weight. In 1878 Nilson and Pettersson re-determined the specific heat of beryllium, and found the number 0·408 for the temperature interval 0°–100°, hence these chemists concluded that the atomic weight of the metal must be increased by one-half ($13·6 \times 0·408 = 5·6$). If $Be = 9·1$ the oxide of beryllium is BeO, and the metal is placed in the magnesium group, but if $Be = 13·6$ the oxide is Be_2O_3, and the metal is placed in the aluminium group. But there is no place in Mendelejeff's classification of the elements according to the magnitude of their atomic weights for a metal with the atomic weight 13·6, forming an oxide M_2O_3, and exhibiting the properties of beryllium. The value of Mendelejeff's classification is however so great that chemists were not inclined to alter the atomic weight of beryllium except upon most cogent evidence.

Nilson and Pettersson have recently repeated their determination of the specific heat of beryllium, and find these numbers —

0°–50° spec. heat = 0·3973 0°–100° spec. heat = 0·4246,
0°–200° ,, = 0·475 0°–300° ,, = 0·5055.

If the atomic weight is taken as 13·6 then the atomic heat for the interval—

0°–50° = 5·46 0°–100° = 5·79 0°–200° = 6·48 0°–300° = 6·9,

hence the Swedish chemists conclude that the atomic weight of beryllium is 13·6

But in the last number of the *Berichte* of the German Chemical Society, Lothar Meyer has calculated, from Nilson and Pettersson's numbers, the true specific heat (*i.e.* the ratio between the quantity of heat required to raise unit weight of the given substance through 1°, starting from the given temperature, and the quantity of heat required to raise unit weight of standard substance through 1°, also starting from the given temperature) of beryllium for various temperatures his results are as follows:—

(γ = true specific heat at temperature t. $\Delta\gamma$ = value of increase of specific heat for 1°)

t		t		t	
23°	γ = 0·3973	73·2	γ = 0·4481	157°	γ = 0·5193
	$\Delta\gamma$ = 0·00101		$\Delta\gamma$ = 0·00085		$\Delta\gamma$ = 0·00063

t 256·8 γ = 0·5819.

Hence the atomic heats of beryllium are —

t	Be = 9·1	Be = 13·65
23°	3·62	5·43
73°	4·08	6·12
157°	4·73	7·10
257°	5·29	8·94

The value of $\Delta\gamma$ decreases as the temperature rises, in this respect beryllium resembles boron, carbon, and silicon. For other elements whose specific heats increase with increase of temperature the value of $\Delta\gamma$ also increases. Lothar Meyer therefore concludes that beryllium is analogous to boron, carbon, and silicon, in that its specific heat increases as temperature increases, and in that the value of this increase is less for 1° at high than at low temperatures Hence the atomic weight of beryllium is almost certainly 9·1, the oxide is BeO, and the metal finds its place in Mendelejeff's system of classification of the elements according to their atomic weights.

THE PHOTOPHONE

MANY readers of NATURE will doubtless be glad to know that Mr. Graham Bell's extraordinary experiments may be repeated on a small scale with very simple apparatus, no special appliances being required beyond the mirror transmitter and the selenium receiver, both of which may be easily constructed. I propose to give a short description of an arrangement which has in my hands been very successful

The mirror is made of the thin mica which is sold by opticians for covering *carte de visite* photographs. It is cut by scissors into a circle 2¼ inches in diameter, and silvered by the process for silvering glass specula The box in which it is mounted is an ordinary wood turned box 2½ inches in diameter A circular hole of about 2 inches diameter is cut in the lid, behind which the mirror is laid with the reflecting side outwards, a flat ring of vulcanised india-rubber of suitable size and thickness being placed behind the mirror, when the box is closed the ring should hold the mirror firmly in position. If the lid screws on, so much the better. At the bottom of the box is cut a hole, into which is glued one end of a flexible speaking-tube 18 inches long, having at its other end a wooden mouthpiece. It will be found convenient to attach a short wooden arm to the box in a direction perpendicular to its axis. By means of this arm the transmitter may be held in a clamp in any desired position.

This completes the transmitter as described by Mr. Bell. I have made a small addition which, though not essential, is a decided improvement. At the back of the mirror I cemented a disk of calico 1 inch in diameter, in the centre of which had been previously inserted a loop of silk half an inch long. A hole ⅛ inch diameter is bored perpendicularly in the side of the box at a point about ½ inch from the mirror end of it, and in this hole is inserted a piece of watch-spring 1⅛ inch long, with its flat sides parallel to the top and bottom of the box The spring is fixed into the hole with wooden plugs so that one end is flush with the outer surface of the box; the other end where it intersects the axis is bent into a shallow hook Into this hook is slipped the silken loop, and the tension of the spring draws the mirror into a slightly concave form, and seems to make it respond more perfectly to sound vibrations.

By far the most important part of the whole apparatus is the selenium "cell." After making some dozens of different forms, most of which were more or less sensitive, but none satisfactory, I tried the one now to be described, which turned out very successful. Take a slip of mica 2¼ inches long and ¾ inch broad, and beginning at ¼ inch from one end, wind round it in the form of a flat screw some No 40 copper wire. The pitch of the screw is 1/16 inch, that is, each wire on the two faces of the mica is 1/16 inch from its neighbours Continue winding up to ¼ inch from the other extremity, then fix the two ends of the wire by passing them through holes drilled in the mica Now take a second wire and carefully wind this on beside the other, thus forming a second screw, the threads of which are midway between those of the original one Fix this as before Great care must be taken that the two wires do not touch each other at any point: it will be well to make sure of this by testing with a galvanometer before proceeding further If a lathe is at hand, the tedious operation of winding may be very greatly facilitated. Turn a cylinder of hard wood 4½ inches long and 1 inch in diameter: cut this cylinder longitudinally into two equal parts, and between the two semi-cylinders thus formed place, sandwich-like, a slip of mica of equal breadth. Secure the ends with screws Smooth down the whole in the lathe, and when the edges of the mica are quite flush with the surface of the wood, cut upon the cylinder a screw of thirty-two threads to the inch. On removing the mica from the cylinder its two edges will be found to be beautifully and regularly notched Wind the first wire into alternate notches, and the second into the others The wire should be annealed to take away its springiness and make it lie flat, and the mica should be stout enough to bear tight winding without buckling.

For the succeeding operation a retort-stand at least 15 inches high is convenient. Fix one ring 15 inches above the foot, on a lower ring stand a medium-sized Bunsen burner On the top ring lay a flat sheet of brass 1/16 inch thick, and on the brass a piece of mica (to save waste selenium). Place the embryo cell on the mica, laying small weights on its two ends to keep it steady and bring it into closer contact. Having brought the Bunsen burner close under the brass, melt a few grains of vitreous selenium in a small spoon and let four or five drops fall upon different parts of the cell Spread the melted selenium evenly over the surface with a slip of mica, pressing it well between the wires. During this process the temperature must be carefully regulated by raising or depressing the burner If it is not high enough, the selenium will begin to crystallise, if too high, the selenium will gather up into drops, being apparently repelled from the surface of the cell. The temperature should in fact be just above the fusing point of crystalline selenium. When a smooth surface is obtained, quickly remove the cell with microscope forceps and let it cool. Its surface will now be smooth and lustrous.

The cell must next be annealed. And here my expe-

rience differs in a remarkable manner from that of Mr. Bell, as stated in his celebrated lecture. It is true that selenium may be rendered crystalline in "a few minutes," but in this condition I find it far less sensitive to light than after it has undergone a process of long heating and slow cooling. My method is as follows.—The brass plate being cool, lay the cell upon it again, and place the burner at its lowest possible point. The selenium will soon begin to crystallise, as evidenced by its surface assuming a dull leaden appearance. (If the crystallisation has not begun in five minutes, raise the burner an inch or two.) In from five to ten minutes the whole of the selenium should be crystallised. Then very gradually raise the burner until signs of fusion just begin to appear. This will probably take place when the flame is within 3 inches of the brass. Instantly remove the burner, and in about ten seconds re-crystallisation will occur. Now fix the burner $\frac{1}{2}$ inch below the point at which it was when fusion commenced, and let it remain for four hours, merely looking at it from time to time to ascertain that, owing to increase of gas pressure or other causes, the heat has not become too great. After four hours begin the cooling by lowering the burner an inch or two, and repeat this operation every ten or fifteen minutes, until the burner is at its lowest point. Then slightly lower the gas-flame at short intervals, until it is finally extinguished. When the brass plate is quite cool the cell may be removed.

I may mention that I first made a cell of this form, which I believe to be original, on October 28.[1] If the two wires were wound on a cylinder made of some suitable non-conductor (*e.g.* slate) with a double screw cut upon its surface, a cell might be formed which, it appears to me, would unite all the advantages of Mr. Bell's with far greater simplicity.

My experiments were made with the transmitter and selenium cell above described, a magic-lantern with a 4-inch condenser, the focussing lenses being removed, two plano-convex lenses obtained by separating a 3½-inch condenser, a "blow-through" lime-light, a battery of eleven cells (small Leclanché's answer well), and a pair of Bell telephones. It is essential that the bobbins of the latter be wound with finer wire than that generally used. Mine contain No. 40 (instead of 35 or 36), and I intend to try 42. Their diameter is also larger than usual—1$\frac{3}{4}$ inch.

The transmitter is clamped so that its axis is inclined at an angle of about 30° to that of the lantern condenser, the centre of the mirror being 7 or 8 inches from the centre of the condenser; and the position of the lime-light is so adjusted that the condensed rays may just cover the whole surface of the mirror.

The reflected beam is rendered as nearly parallel as possible by one of the plano-convex lenses (this can only be done approximately), while the other, placed a foot or two away, concentrates the light upon the selenium cell, forming an elliptical image of the mirror. The major axis of the ellipse should be parallel to the length of the cell, and the minor axis slightly longer than its width. A great deal depends upon the focussing, and the best results have been obtained when the image of the mirror was not quite sharp. The selenium cell is joined in circuit with the battery and the pair of telephones, the latter being for obvious reasons placed in a distant room. The arrangements are now complete, and a person listening with a telephone applied to each ear will, if everything is right, plainly hear words which are spoken into the transmitter. When I first made the experiment I was so much astonished at the distinctness of the reproduction that I believed that one of the battery connections must be defective, thus acting like a microphone. This was disproved by screening the mirror, when all sound instantly ceased.

Though the articulation is not perfect, it is far better than I had expected, judging from the accounts of the performances of the photophone in Paris. A leading article might not be altogether intelligible, but ordinary colloquial phrases are readily understood. The loudness of the reproduced speech varies in an unaccountable manner. Sometimes the voice is rendered almost as loudly as in an ordinary telephone; at other times, under apparently the same conditions, it is scarcely audible. Alternations from loudness to faintness, and *vice versâ*, frequently occur in a single sentence.

The distances across which the beam is carried have varied in my experiments from 1 foot (when the two plano-convex lenses were in actual contact) to rather more than 4 feet.[1] With a larger receiving lens this distance could be greatly extended, especially if the electric light were used.

For the "musical" effects produced by an interrupted beam I use a disk of zinc 1 foot in diameter, having eight radial slits cut in it, and mounted upon a vacuum tube rotator. The cell is placed 6 inches from the lantern condenser, and the disk made to rotate close before it. The sound produced is very loud, and can be heard when the telephones are at a distance of a foot or more from the ears.

It is very singular, that whereas I have been so successful in repeating Mr. Bell's more complex experiments, I have utterly failed in all attempts to produce sound by the simple incidence of an interrupted beam upon a thin diaphragm. I have experimented with disks of ebonite varying from $\frac{1}{64}$ to $\frac{1}{4}$ inch in thickness, and with several metals, and can only suppose that my source of light is not sufficiently powerful.

SHELFORD BIDWELL

[1] If a larger surface is desired two or more of these cells may be placed together side by side, the ends of the wires being properly connected. The width of $\frac{3}{4}$ inch for a single cell cannot be much exceeded, because the expansion produced by the heat necessary for melting the selenium would make the wires on a wider surface so loose as to touch each other.

[1] With a 5½-inch receiving lens the distance has been increased to upwards of 10 feet.

THE CHRONOGRAPH

MESSRS. E. DENT AND CO., of the Strand and Royal Exchange, London, have been for some time past at work upon three galvanic chronographs of unusual accuracy and power. They surpass in both respects, so far as we know, any similar instruments yet constructed, and we believe, therefore, some account of them will be interesting to our readers. They are destined respectively for the Royal Observatory of Brussels, for the Japanese Government, and for the Egyptian Government.

The advantages of the "chronographic" registration of the times of observations in observatories are not to be gainsaid. In the absence of any such arrangement an astronomer, whilst watching through his telescope, has to compute the time by counting up the clock-beats. More often than not he will find that no clock-beat exactly coincides with the instant of his observation. He must then reckon the difference—the fraction of the second elapsed—by judgment as best he is able. Skilled observers can reckon to tenths of seconds, but these are large and coarse amounts compared with what may be noted upon such chronographs as those we are referring to. In any case the astronomer must make a hurried memorandum of his results, otherwise he is liable to forget them.

The Astronomer-Royal was, we believe, the first to introduce a system of astronomical chronographic measurement into England, and he designed and had constructed at the Royal Observatory a large apparatus for the purpose. The reader must bear in mind that though differing in some respects both in their mechanism and the means employed, the chronographs we are going to describe are fundamentally the same as the Astronomer-Royal's.

C C (see Fig. 1) is a cylinder around which one thickness of paper is wrapped, and underneath it is a long screw W W. A wheel on the axis of C C gears into one mounted on W W; thus when the cylinder turns, the screw turns. W W is tapped through the lower portion of a carriage K (compare Fig. 2), and K rests on rails parallel with W W. When the screw W W turns, K cannot turn too, and is therefore propelled by the screw up or down the rails underneath the cylinder.

L is clockwork which drives the screw, and consequently the cylinder and carriage. The rapidity with which L moves is regulated by the pendulum P P. P P is a conical pendulum; that is, instead of oscillating, it swings round in the surface of a cone. P P is suspended by two pairs of springs S S, S S at right angles to each other.

Let us consider the actions of C C and K (see Fig. 2). K carries two prickers, one of which is placed in electrical communication with the Observatory standard clock. It

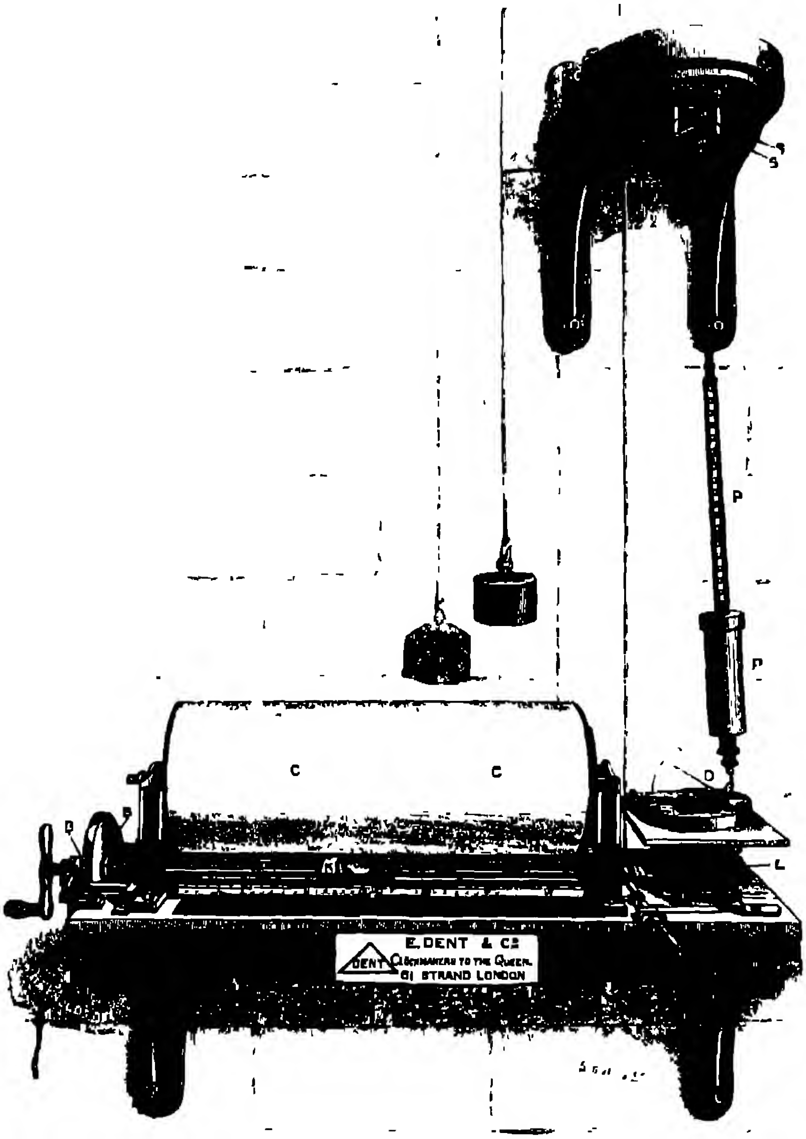

FIG. 1

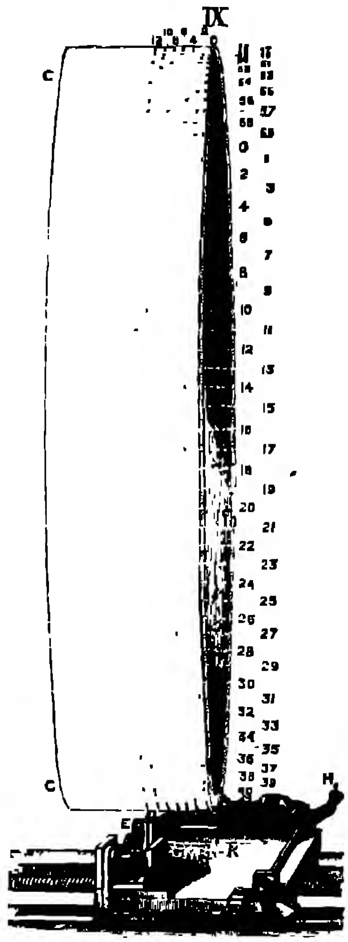

FIG. 2

is so arranged that at every beat of the standard clock (except the 60th second of each minute) the pricker shall rise and puncture the paper wrapped round the cylinder. Now suppose that whilst the clock keeps pricking, the cylinder is turning, and the carriage K moving to the left Then we shall get a succession of pricks marked off upon the cylinder in the form of a slightly inclined spiral, and the distance between each prick will represent one second. Every 60th prick (or second) being omitted, the occurrence of each minute is easily distinguished.

The carriage K carries another pricker alongside the clock-pricker—this is the observation-pricker. The observation-pricker is placed in electrical communication with any instrument in the observatory the astronomer may be going to use, and it is so arranged that the astronomer by merely pressing down a stud can cause the observation-pricker to rise and puncture the paper on the cylinder. This it will do somewhere alongside the spiral of clock-pricks. By reference to the latter the time of the observation can then be determined to the $\frac{1}{10}$th of a second.

Let us examine the pricks on the cylinder (Fig. 2). The spiral of the clock-pricks winds around the cylinder

from left to right. As the cylinder turns once in two minutes, there is between each prick and its fellow similarly positioned on the next spiral a difference in time of two minutes. As stated above, we note by the absence of the pricks the occurrence of the minutes. By reference to the figures placed (for explanation) along the top and side of the section of the cylinder, we see that the time of the highest prick on the left-hand spiral was 9h 12m 46s Following the course of the spiral down towards the

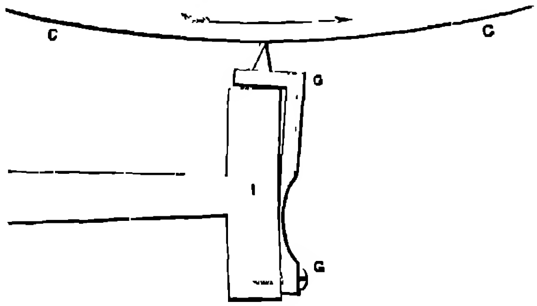

FIG 3

pricker which is tracing it, we first pass the blank line indicating the occurrence of the next minute, and then come to three observation-pricks at about the 8th and 9th seconds beyond it These in practice would be measured off and their values determined to the $\frac{1}{50}$th or $\frac{1}{100}$th of a second. There are other observation-pricks at the 22nd second, the 24th, and 25th, and there is a group of others at about the 40th.

When all the observations have been reckoned up the paper is put away, and it is not the least advantage of

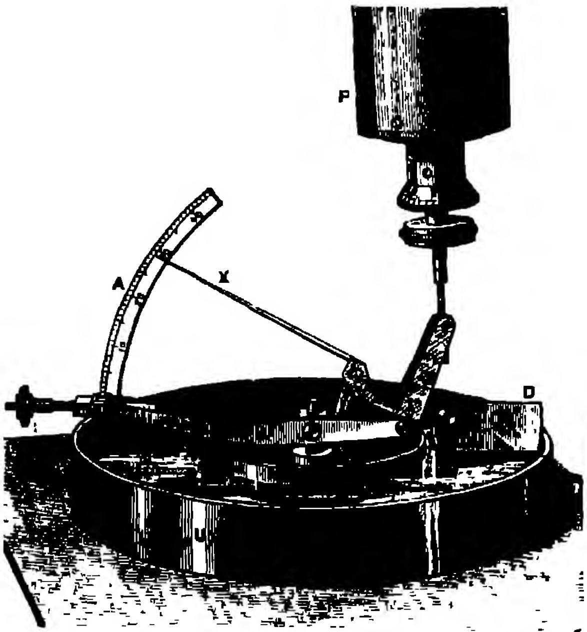

FIG. 4.

the "chronographic" method that in any case of doubt the original observation can be itself referred to years afterwards.

As the paper is moving whilst being punctured, the prickers have to be mounted on springs to enable them to yield a little. In Fig. 3 is a side view of the pricker, G G being the spring, and C C a portion of the cylinder.

There is no difficulty in reading off the observations after a little practice: but in order to facilitate the eye in following the sequence of the punctures—before the paper is used a continuous spiral line is ruled upon it which shall exactly correspond with their course This is done in the following way (see Fig. 1).—At T are two clutch-wheels, which connect the screw and cylinder with the clock-work L. By moving a lever near them the clock-work is thrown out of gear, and simultaneously the winch on the left is thrown into gear with the screw On the carriage K (see Fig. 2) is a little roller E, and by moving a handle this is sprung up against the paper on the cylinder The winch before referred to is now turned, the cylinder rapidly revolves, and the carriage quickly traverses the screw, the spiral line meanwhile being traced by the pressure of E upon the paper of the cylinder. To prevent damage to the prickers during the operation, the act of disengaging the clock-work breaks their electrical communication, and they can neither of them be raised until the clutch-work is restored. The cylinder moves very swiftly whilst the line is being traced, and were it brought to a standstill suddenly great damage would be done. To prevent this it is arranged that when the carriage K is approaching either extremity of the screw it shall work a brake arrangement B B, which brings the machinery quietly to repose The act of putting the clutch-wheels T into position again also releases the brake. The clutch-wheels T are mounted on a spring, so that should their teeth not correspond when they are put into gear, one will give and wait for the other to overtake it.

It is desirable that the clock L should drive C C with great uniformity; and as the time of a conical pendulum is affected in a very great degree by any variation in the force of the clock-train, a special governing arrangement, the invention of the Astronomer-Royal, is employed. U (see Fig 4) is a trough filled with glycerine and water. Power reaches the pendulum by means of its connection with the vertical spindle seen at the centre of the trough, which rises from the clock-work. In this connection there is a joint, and a dipper D forms part of it. Too much power drives out the pendulum, and it would then go faster, were it not that the dipper, entering the glycerine and water more deeply, checks its motion On the other hand, whenever the power falls off the pendulum performs a smaller circle, thereby lifting the dipper a little more away from the liquid, and diminishing the resistance in exactly the same proportion as the force. The pointer X is a very delicate index of the angle the pendulum is swinging. The compensatory action of this governor is very considerable, doubling the power produces no perceptible difference in the time. The quickness with which it works is surprising, an infinitesimal change in the power is immediately indicated on the scale A, showing how well the apparatus is doing its work.

To prevent damage to the governor and the more delicate clock-wheels by any sudden check to the cylinder, a ratch-wheel arrangement has been introduced, which, when the cylinder is suddenly stopped, enables the pendulum to run on until it comes to rest gradually, by want of power.

Fig 1 gives a very faint idea of the dimensions of the apparatus The cylinder C C is 12 inches in diameter, and 30 inches long. Its weight is about 70 lb. The space between each seconds prick is $\frac{3}{10}$ inch, and the distance between the successive turns of the spiral of pricks $\frac{3}{20}$ inch. There is room on the paper for 200 spirals, and as each is more than one yard long, we can get more than 200 yards ($6\frac{2}{3}$ hours) of continuous observation without disturbing the instrument. There is always a spare cylinder covered with paper kept ready to replace the first.

The iron base-plate on which the instrument is mounted weighs over 3 cwt., the rails on which the carriage K runs are cast in one piece with it, and, along with all other bearing surfaces are planed. The pendulum, which weighs some 18 lb., and is compensated, goes round once in two seconds. Its suspension-piece weighs 2 cwt. As

regards the accuracy of the construction of these chronographs, the best criterion is to be found in the force that is required to work them. We find that 7 foot-pounds per hour drives the clock-work and pendulum; 7 foot-pounds more drives the carriage as well; and only 3 foot-pounds more is wanted for the cylinder—17 foot-pounds per hour for the whole instrument. Considering the resistance of the carriage, the resistance of the glycerine, and the weight of the cylinder, we think the result as surprising as it is satisfactory

THE BELGIAN ENTOMOLOGICAL SOCIETY

IN April, 1855, a circular with ten signatures was addressed to entomologists residing in Belgium, proposing the formation of a National Entomological Society, the students of Insecta and allies having at that time no organisation, no central meeting-place for interchange of ideas, no special medium in which to publish the results of their researches. The proposal was met by cordial approval, and the first volume of the *Annales* of the newly-formed Society, published in 1857, indicated a strength of forty-seven effective and four honorary members, with Baron de Selys-Longchamps as president. At first its publications were occupied almost entirely by subjects concerning the Belgian fauna, the volumes were thin, and each represented the work of more than one year. The Society was however well grounded, and notwithstanding occasional short periods of depression, it gradually increased in the number of its members, in the wideness of the scope of the papers read at its meetings, and in reputation as one of the leading entomological societies. Naturally the size of the volumes of the *Annales*, and the frequency of their appearance, also increased, and now the Society produces a volume each year that no similar society need be ashamed of. The twenty-second volume appeared in 1879, showing that the weakness inherent on infancy was soon overcome. The list in this volume shows a total of 171 effective Members (including many foreigners, of whom, however, only six are our own countrymen), twelve Honorary Members (including Messrs. Stainton and Westwood), with the addition of Corresponding and Associate Members It had also at that time acquired the distinction of being recognised by the State and of receiving a certain amount of State aid.

On October 18, 1880, the Society celebrated its twenty-fifth anniversary, rejoicing in the attainment of more than its majority, on which occasion the present President (M. Weinmann) read a short congratulatory address, and the indefatigable secretary (M. Preudhomme de Borre, to whom the Society owes much of its recent success) gave an instructive sketch of the history and progress of the Society On that occasion an especial honour was bestowed upon its first president, Baron de Selys-Longchamps (recently elected President of the Belgian Senate), by conferring upon him (in spite of his protestations) the title of Honorary President, a graceful tribute to one who for so long had continually used his energies, his social and scientific position, and his purse in furthering its interests.

Even apart from purely scientific considerations, the history of Belgium is so indissolubly mixed up with our own, and the feeling of fraternity so close, that all students of entomology in this country cannot but reciprocate the mutual congratulations that passed on this occasion between the native members, and the hearty and unaffected demonstrations of friendship accorded to our own entomologists who have attended the meetings of the Society show how warmly they welcome those of the foreign members who occasionally visit Brussels. The meetings are held in a room in the Royal Natural History Museum, in which is the library, and in connection with the entomological collection of the Museum. The annual subscription is small, and entitles the members to receive all the publications, including elaborate separate reports of the proceedings at the monthly meetings. We hope soon to see Englishmen figuring far more numerously in the lists of members. R. McL.

A GENERAL THEOREM IN KINEMATICS

THE following theorem with regard to the motion of a rigid body will doubtless be interesting to mathematical physicists —

In all cases of the motion, parallel to one plane, of a rigid body there is at every instant a point, J, of no acceleration, in the plane of motion; the acceleration of every point, P, in the plane is in magnitude directly proportional to the distance, JP, and its direction makes with JP an angle which, though varying with the time, is at any instant the same for all points in the body.

If ω is the angular velocity of the body at any instant and $\dot{\omega}$ the angular acceleration, the angle between JP and the direction of acceleration of P is

$$\tan^{-1}\frac{\dot{\omega}}{\omega^2}$$

We have therefore in all cases of uniplanar motion of a solid body an *instantaneous acceleration centre*, which is analogous to the ordinary instantaneous [velocity] centre.

Of course the ordinary equation

$$I\dot{\omega} = L,$$

which holds for motion round an axis fixed in space and in the body, and which expresses that the moment of the external forces about the axis is equal to the moment of the forces of inertia, holds also for the instantaneous acceleration centre.

As a particular case, whenever a solid moves with constant angular velocity, the accelerations are all directed towards the same point at any instant, and it follows that the resultant stress exerted over the surface of any little lump of the matter is a force directed to this point, if no continuous forces act

This centre can be in any case geometrically constructed by a rule analogous to that for the ordinary instantaneous centre

When I had hit upon this theorem I mentioned it to Prof. Wolstenholme, who at once looked out for its extension to three dimensional motion The result is very simple.

In all cases of the motion of a solid body there is at every instant a point, J, of no acceleration, and if at J there be drawn two axes, JA and JB, which are those respectively round which the resultant angular velocity, ω, and the resultant angular acceleration, $\dot{\omega}$, take place, the acceleration of any point, P, is compounded of two—one along the perpendicular, p, from P on JA, and the other perpendicular to JB and to the perpendicular, q, from P on JB, these two components being, respectively,

$$\omega^2 p \text{ and } \dot{\omega} q.$$

It seems surprising that such a simple and general property of the motion of a rigid body should not have been well known long ago GEORGE M. MINCHIN

Royal Indian Engineering College,
Cooper's Hill, November 6

NOTES

THE awards of medals for the present year made by the President and Council of the Royal Society are as follows:—The Copley Medal to Prof. James Joseph Sylvester, F.R.S., for his long-continued investigations and discoveries in mathematics; a Royal Medal to Prof. Joseph Lister, F.R.S., for his contributions on various physiological and biological subjects published in the Philosophical *Transactions* and *Proceedings* of the Royal

Society and elsewhere, and for his labours, practical and theoretical, on questions relating to the antiseptic system of treatment in surgery; a Royal Medal to Capt. Andrew Noble, F.R.S., for his researches (jointly with Mr. Abel) into the action of explosives, his invention of the chronoscope, and other mathematical and physical inquiries, the Rumford Medal to Dr. William Huggins, F.R.S., for his important researches in astronomical spectroscopy, and especially for his determination of the radial component of the proper motions of stars, the Davy medal to Prof. Charles Friedel of Paris for his researches on the organic compounds of silicon, and other investigations.

WE regret to have to record the death of M. d'Almeida, secretary of the French Société de Physique, and editor of the *Journal de Physique*. M. d'Almeida published a "Traité de Physique" in collaboration with M. Boutin. The *Comptes rendus* of the Academy of Sciences contain a number of his memoirs.

MR. SPOTTISWOODE, president of the Royal Society, was present at the sitting of the French Academy of Sciences on the 15th inst. He witnessed experiments made at Meritens' workshop on the magneto-electric engines which have been ordered by the Trinity House. The trials were successful.

SIR EDWARD REED writes from Corunna to the *Times* of yesterday, pointing out, as we were able to do last week, that the reports as to the injury sustained by the *Livadia* have been greatly exaggerated, and were not more than a few Clyde shipwrights could have repaired in a couple of days. There was no difficulty in getting the two injured compartments put to rights, barring the laziness of the French shipwrights. The *Livadia* returns to Ferrol for the winter, as her services are not required by her Imperial owner.

FURTHER details concerning the earthquake in Austria on the 9th confirm the reports as to its extent and severity. At Agram there were three shocks—the first, at 7.24 a.m., was the most formidable and lasted ten seconds; the second, also severe, occurred at 7.30, while the third, which was much the weakest, took place at 8.28 a.m. The first shock is described as circular. It was followed by violent oscillations from north-north-east to south-south-west. After it the whole town was covered by a dense cloud of dust caused by the falling down of chimneys, walls, and houses in every direction. From Laibach, Marburg, Klagenfurt, Kanizsa, Serajevo, Derwent, Brod, Pola, Trieste, Cilli, and the region of the river Drave, intelligence has been received of more or less severe shocks about the time of the first great shock in Agram. The earthquake was also felt in both Vienna and Pesth, but so slightly that it attracted the notice of only a few persons. The direction of the motion was everywhere the same, from north-east to south-south-west. As far as can be judged from the information hitherto received, the movement extended from the 44th to the 48th degree north latitude, and from the 32d to the 37th degree of east longitude (Ferro). From almost every district on the right bank of the Danube there is news of a greater or less disturbance with more or less damage done, while from the other side there is no such intelligence from even a single place. It was also felt at Szegedin and on the Theiss. Slight shocks were also felt on the night of the 9th and morning of the 10th, at Agram, and at noon on the 11th, a shock caused a number of houses to fall; the last was preceded by slighter shocks at 5.30 and 11 a.m. The disturbance was continued on the evening of the 11th, and on the morning, afternoon, and evening of the 12th. In the neighbourhood of Agram two mud volcanoes are said to be formed and in full eruption, and several hot springs have risen. The earth has also been rent in many places in the open country, and considerable quantities of mud with hot water and sulphur have been thrown out. The Vienna correspondent of the *Times* writes under the date of November 14: "The earth has been rent in many places in the open country, and considerable quantities of mud and hot water with sulphur have been thrown out. One of the largest of these rents is near the village of Resnik. Agram has often been visited by these earthquakes, especially within the last few years. Indeed scarcely a year has passed without more or less violent shocks." On the night of the 15th–16th there were at least five shocks at intervals between midnight and 4 a.m. Geologists have gone from Vienna and Berlin to Agram to study the phenomena more closely.

MR. J. MUNRO has drawn our attention to the fact that in NATURE, vol. xviii. p. 169, there appeared a short letter signed "J. F. W." and dated from Kew, June 3, 1878, suggesting the principle of Prof. Bell's photophone. The letter is as follows:—"Till now I have looked in vain for any account in NATURE of experiments with the telephone or phonoscope, inserted in the circuit of a selenium (galvanic) element (see NATURE, vol. xvii. p. 312). One is inclined to think that by exposing the selenium to light, the intensity of which is subject to rapid changes, sound may be produced in the phonoscope. Probably by making use of selenium, instead of the tube-transmitter with charcoal, &c., of Prof. Hughes, and by exposing it to light as above, the same result may be obtained. I should be glad to know whether experiments have been made in this direction, for if the above should prove true, there is no doubt that many applications would be the result."

OUR entomological readers will be glad to know that Mr. McLachlan will still continue his valuable services to the *Zoological Record*, reporting as usual on the groups of the Neuroptera and Orthoptera. Mr. Rye will henceforth confine himself to editorial work, while the groups hitherto recorded by him will be undertaken by Mr. Kirby, who will also do the Coleoptera.

LARGE additions are now being made to the Muséum d'Histoire Naturelle in the Jardin des Plantes at Paris. A new front is being erected and two new sides, which, combined with the former "Galerie," will form a hollow square. This square will be covered with glass and used for the exhibition of skeletons of whales and other specimens of inordinate dimensions. The total cost of these buildings is estimated at five million francs (160,000*l*.).

UNDER the auspices of the Russian Geographical Society M. Merejkovsky has been investigating the prehistoric anthropology of the Crimea. He has explored numerous caverns and made large collections of skulls, and the conclusion he comes to is that the age of stone in the Crimea may be divided into three periods: 1. Diluvian period, with mammoth fauna and arms of large dimensions, rudely worked. 2. Alluvial period, with contemporaneous fauna and the use of the arrow. 3. A later period, remarkable for the use of stone arrows, with scarcely any arms of large dimensions. In the Ural M. Malakhof has obtained important results, both geodetical and anthropological. He believes he has discovered on the Neiva, 75 versts from Ekaterineborg, traces of a prehistoric city.

A REGULAR analysis of the air is carried on by M. Davy at Montsouris. It has been found that the number of bacteria was twice greater than usual during the last period of high mortality.

THE President of the French Republic has established telephonic communication between the Elysée and the Chamber of Deputies, as well as the Senate. The first message of this instrument was the intelligence that the Cabinet had been placed in a minority.

AN interesting exhibition took place on Sunday, the 14th, at the Paris Conservatoire des Arts et Métiers, Rue St. Martin. The *portefeuille* of Vaucauson was opened for the first time to

public inspection. On this occasion the most important documents of this collection were affixed to the walls, with a number of other articles belonging to the archives. The most interesting is certainly the original letter written by Fulton to Mollard explaining to him the principles of steamboat construction. The letter is very long and exhaustive, and is accompanied by a drawing. M. Mollard returned a very cold answer after having meditated for a full month, and he says that "Mr Fulton's communication will be lodged in the archives of the Conservatoire." The date of Fulton's communication is the beginning of Pluviose, An. 11; Mollard's answer is not exhibited, but has been seen by our correspondent.

THE Jablochkoff light has been introduced by M. Hervé Mangon into the Conservatoire. It will be fed by a Gramme machine, which the establishment has purchased for its constant use. The light will be placed in the amphitheatre, where M. Hervé-Mangon delivers, twice a week, his own lectures.

THE lighting of the Victoria Station of the District Railway by means of the Jablochkoff electric light has been so successful that it has been also applied to the Charing Cross Station, and will shortly be introduced at Earl's Court.

M. MARTIN is engaged in polishing the object-glass of the large refracting telescope now building at the Paris Observatory. The diameter of this exceptional lens is 73 centimetres, and its weight 200 kilograms. The quality of the glass having proved defective it has already broken twice, and the operation is now being made on the third casting.

ON the occasion of the opening of the Ronalds Library at the Society of Telegraph Engineers, a considerable number of rare and curious books relating to electricity, magnetism, navigation, &c., was exhibited. A list of these has been printed and would be valuable to any one interested in the history of the departments of science concerned.

A GOOD example of the thoroughness of German education is given in the publication by Brockhaus of Leipzig of an "English Scientific Reader," edited by Dr. F. J. Wershoven, its purpose being to familiarise students with the style and terms used by the best English scientific writers. The first part relates to physics, chemistry, and chemical technology, and the extracts are made with great judgment. Among the authors from whom selections are made are Clerk-Maxwell, Fleeming Jenkin, Crookes, Roscoe, Lockyer, Rankine, Bloxam, George Wilson.

WE have received the first two volumes of a new "Bibliothèque Belge," for the popularisation of the sciences and arts, published at Mons by Manceaux. The two volumes received are "Traité élémentaire de Météorologie," by MM. J. C. Houzeau and A. Lancaster, two names well known in connection with this subject, and "Zoologie élémentaire," by Prof. Felix Plateau, whose name must also be familiar to our readers in connection with original research in a special department of the subject. Both volumes are well printed and illustrated. Among the volumes to follow are "Palæontology and Conchology," by A. Briart; "Geology," by F. Cornet, "Botany," by F. Crépin; "Mineralogy," and "Mineral Physiology," by L. L. de Koninck; "Mechanics," by H. Hubert, "Astronomy," by M. Niesten, "The Beginnings of Animal Life," by E. van Beneden, and "Physics," by vand der Mensbrugghen.

PROF. CORNELIUS DOELTER of Gratz was to proceed on the 15th inst. to Paris, thence to set out on a mission of scientific investigation to West Africa.

ACCORDING to official reports of the statistics of Bosnia and Herzegovina, these contain 1272 parishes, 43 towns, 31 markets, 5042 villages, 189,662 houses, 200,747 dwellings. Of the 1,158,440 inhabitants 607,789 are male, 550,681 female, 448,613 Mahommetan confession, 496,761 Greek-Oriental, 209,391 Roman Catholic, 3426 Jewish, 249 other confessions.

THE Procureur-General of Paris having complained, in his official address on the occasion of the opening of the courts, that the legal experiments in cases of poison were executed without sufficient precautions being taken against the professional prejudices of the operator, all the medical advisers of the criminal courts in Paris sent in their resignation, after having taken the advice of the Dean of the School of Medicine and other scientific authorities. Their number is nineteen.

A FAIRLY satisfactory Report is given by Surgeon-Major Bidie on the Government Central Museum at Madras. The number of visitors, especially female, continues to increase, and the special arrangements for native ladies attracted an average of 116 on the afternoon of the first Saturday of each month.

THE *Garden* has increased its size and reduced its price, introducing several improvements.

LORD GIFFORD, one of the Scotch judges, in opening the session at the Edinburgh School of Art the other day, summed up very neatly the advantages which a full and accurate scientific knowledge would bestow on those who were engaged in any practical work whatever—(1) That scientific knowledge of their subject would make work, whatever it was, intelligent, not mechanical; (2) it would make their work skilful and easy, (3) it would enable them to produce more exact and perfect work; (4) it would make their work advancing and progressive; and (5) it would make their lifework in itself delightful, and a source of pure and profound joy.

A VERY favourable Twelfth Report of the Working Men's College is issued. This institution completed its twenty-fifth year last year, and during its existence has doubtless done much good. The science classes have attracted an increasing number of students in recent years.

UNDER the title of "The Free Libraries of Scotland" some useful information is brought together in a pamphlet by "An Assistant Librarian." The towns in Scotland in which there are free libraries are Airdrie, Dundee, Forfar, Galashiels, Glasgow (Mitchell Library), Hawick, Paisley, Thurso. The University towns of Edinburgh, Aberdeen, and St. Andrews are still without such useful institutions; the Act has been adopted in Inverness and Dunfermline, Arbroath has twice rejected the proposal to adopt the Free Libraries Act.

WE are glad to notice that the Highbury Microscopical and Scientific Society is increasing in numbers and has some good papers promised for the new year. It gave its fourth annual *soirée* at Harecourt Hall on October 14, and the president, Mr. Frederick Fitch, F.R.M.S., gave his address on the "History of the Microscope and Microscopic Research" on October 28. On Saturday, the 13th inst., a visit will be paid to the Museum of Practical Geology under the guidance of Prof. Rudler, F.G.S.

IN the *Transactions* of the Royal Society of Victoria, April 1880, recently received, the Rev. R. H. Codrington contributes some valuable "Notes on the Customs of Mota, Banks Islands." Since Mr. Tylor in his "Early History of Mankind" so graphically sketched the remarkable custom of the "*couvade*" all information as to its further geographical distribution is ethnologically valuable, and Mr. Codrington here adds the Banks Islands to the area in which it is practised. There is also a tradition that among the inland mountains there is or used to be a race of wild men, which agrees with the stories that are current in most of the Asiatic Islands. The *Mota* practices here described are not to be confounded with those of the *Motu* of New Guinea.

A NEW destructive insect is recorded from America; *Cetonia inda*, a beetle which, according to the *American Naturalist*, was harmless, feeding on the sap of freshly cut maple-trees, has within two or three years become very abundant and destructive in different parts of New England. During the past summer it collected in great numbers on green corn, "eating the kernels and partly destroying a field in Middleboro, Mass."

FAVOURABLE reports reach us as to the thriving condition of the Botanical Gardens, Peradeniya, Ceylon, under the direction of Dr. Trimen, who recently succeeded Dr. Thwaites. In the experimental nurseries, our contemporary the *Colonies* says, good work was being done. Every effort was being made to extend the cultivation of *Cinchona*, the export of which for the season, up to the date of latest advices, had been 1,135,236 lb. In the district of Kotmale report represented the india-rubber tree as flourishing, and the export of its valuable juice from the colony may, it is hoped, be eventually looked upon for supplementing the falling off in export of this valuable article from the forests where it is indigenous.

THE *Colonies and India* draws attention to the riches of the New Zealand forests in their indigenous timbers. Though the woods of New Zealand, like those of Australia, are by no means unknown in this country, owing to the assistance afforded for making their acquaintance through the various International Exhibitions, they are nevertheless almost unknown in commerce in consequence of their extreme hardness and the cost of freight in bringing such heavy material so long a distance. Our contemporary thinks that the timbers "will become of much greater value when it is more generally known when to cut and how to season them." We are told that experiments in this direction are being made in order to test their value for various purposes. Several of the best woods are enumerated, and it is said of the "Matai" (*Podocarpus spicata*) that Mr Buchanan "reports having found a tree of this species prostrate on a piece of land near Dunedin, which from various circumstances was estimated to have been exposed for at least three hundred years in a dense damp bush under conditions most favourable to decay. It was still however sound and fresh."

MAMMEE APPLES (*Mammea americana*) are, we understand, being exported in quantities from the West Indies to New York. The result of the experiment is being watched with some interest.

IN the last number of the *Revue d'Anthropologie* has appeared not only an excellent photograph of the late Dr. Paul Broca, but also a biographical sketch and a complete list of his various contributions to science. His contributions to medical science commence in 1847, and his first anthropological memoir bears date 1850, from these dates to the time of his death this "Bibliographie" is a record of both untiring industry and scientific production, which will be remembered as long as anthropology remains a science.

OUR ASTRONOMICAL COLUMN

THE SOLAR ECLIPSE OF DECEMBER 31.—Although the eclipse of the sun on the last day of the present year will not in any part of these islands amount to six-tenths of the sun's diameter, it is nevertheless as large a one as will be visible until May 28, 1900, and only that on the morning of June 17, 1890, will compare with it in magnitude in the interval. The *Nautical Almanac* furnishes the results of direct calculations for Greenwich, Edinburgh, Dublin, Cambridge, Oxford, and Liverpool. If to the results for the former three observatories we apply the very convenient Littrow-Woolhouse method of distributing the predictions, we shall have the following formulæ for finding Greenwich mean times of first contact, greatest phase and last contact, and the magnitude of the eclipse at any place within or near to the area comprised:—

		h. m		
First contact	=	1 41.14	− [9.9891] L	+ [9.6113] M
Greatest phase	=	2 36.32	− [9.7942] L	+ [9.3838] M
Last contact	=	3 28.63	− [9.4618] L	+ [8.7599] M

Where the latitude of the place is put = 50° + L, and M is the longitude from Greenwich in minutes of time reckoned positive to the east, and negative to the west. Quantities in square brackets are logarithms.

Or the following may be substituted with sufficient accuracy, the factors of L and M being now numbers:—

		h. m		
First contact	=	1 41.14	− 0·98 L	+ 0·41 M
Greatest phase ...	=	2 36.32	− 0·62 L	+ 0·24 M
Last contact	=	3 28.63	− 0·29 L	+ 0·06 M

and the magnitude will be = 0·368 + 0·013 L − 0·002 M. If we test these formulæ upon Oxford, the latitude of which is 51° 45′ 36″, longitude 5m. 2·6s. W., we have then L = + 1·76°, and M = − 5·04m., then for first contact the expression becomes 1h. 41·14m. + 1·76 × − 0·98 − 5·04m. × 0·41 = 1h. 41·14m. − 1·72m. − 2·07m. = 1h. 37·35m. Greenwich mean time, or applying the longitude − 5·04m. = 1h. 32·3m. agreeing with the *Nautical Almanac*, and similarly for the other phases. The differences from direct calculations will be within 0·2m., if the place is not too distant.

THE DUNECHT COMET.—There appears to be no doubt now that the comet discovered by Mr. Lohse at Lord Lindsay's Observatory on November 7 is the same as that detected by Mr. Lewis Swift at Rochester, N.Y., on October 11, which had not been previously observed in Europe. The elements, according to the calculations of Mr. S. C. Chandler, jun., of Boston, U.S., and those of Dr. Copeland and Mr. Lohse at Dunecht, have great resemblance to the elements of the third comet of 1869, discovered by M. Tempel, and there seems a probability that he may thus be found to have detected no fewer than four comets of comparatively short period. If the revolution of this comet should prove to be performed in a little less than eleven years it will be found that it must approach very near to the orbit of Mars shortly before the descending node, and, which is of more importance, within 0·4 of the earth's mean distance, from the orbit of Jupiter in about heliocentric longitude 257°. Mr. Chandler sends us elements calculated from approximate positions on October 21, 25, 28, and in his letter dated November 2 points out their great similarity to those of the Comet 1869 III., and in a circular received from Lord Lindsay we find an orbit computed from Dunecht observations on November 7, 9, and 10, we have thus for comparison:—

	Comet of 1880 Chandler	Copeland and Lohse	Comet of 1869 Bruhns
T	Nov. 7·714	Nov. 6·6127	Nov. 20·7168
	° ′	° ′ ″	° ′ ″
π	41 41·0	40 24 10	41 17 13
Node	295 25·4	300 49 41	292 40 29
ι	7 21·7	7 22 13	6 55 0
Log. q	0·04262	0·043314	0·042416
Motion	Direct	Direct	Direct.

Mr Chandler's T is for meridian of Washington, the other two for that of Greenwich. An ephemeris which he adds proves the identity of Swift's comet with that found by Mr. Lohse.

It may be remarked that, taken as a whole, there is a distant resemblance to the elements of the comet of Biela.

INTRODUCTORY LECTURE TO THE COURSE OF METALLURGY AT THE ROYAL SCHOOL OF MINES[1]

THE distinguished metallurgist who has held this lecturership since the foundation of the Royal School of Mines, concluded the introductory lecture he delivered more than a quarter of a century ago[2] by pointing out to the students who were then beginning their course that "in proportion to the success with which the metallurgic art is practised in this country will the interests of the whole population, directly or indirectly, in no inconsiderable degree be promoted." This is a fact that none of his students are likely to forget.

Looking back on the actual advance of this country during the

[1] By Prof. W. Chandler Roberts, F.R.S., Chemist of the Mint. Condensed by the Author.
[2] *Records* of the School of Mines, vol. i. pt. i. (1852) p. 127.

past thirty years, and remembering that the success with which any manufacturing art is practised must bear a direct relation to the way in which it is taught, we cannot but feel how greatly this development of metallurgical knowledge must have been influenced by Dr. Percy's labours. During this period the conditions under which metallurgy is practised have changed considerably, for the field of knowledge has so widely extended, the scale on which operations are conducted is now so great, and the mechanical appliances they involve are so varied and complicated, that while the interest of our subject is deepened its difficulty is gravely increased.

In turning to the history of metallurgy, more especially in its relation to chemical science, it is easy to be led away by the charm of the antiquarian riches of our subject into devoting too much time to this kind of literary research, I may remind you however that much of what is both interesting and full of suggestion, even at the present day, is to be found buried in the treatises by the old writers whose work we inherit and continue.

Primitive metallurgical processes are referred to in some of the oldest known historical records, naturally therefore the development of metallurgy as a science must have been long preceded by its practice as an art, an art for which a place has even been claimed among the religious systems of antiquity [1] The earlier literature of the subject consists mainly of descriptions of processes, but it is well known that chemistry was to a great extent built up on a metallurgic basis, and Black's singularly advanced definition of chemistry as the "effects produced by heat and mixture" [2] might well be applied to metallurgy But of all the phenomena of our subject, probably none have more contributed to advance the science of chemistry than those bearing upon the relations between oxygen and lead, indeed the interest attaching to the mutual behaviour of these two elements is so great that I propose devoting a few minutes to its consideration, more especially as I am anxious to indicate the influence of an ancient process on the scientific views of the present day

When lead is melted with free access of air, a readily fusible substance forms on its surface. This substance may be allowed to flow away, or if the metal is contained in a suitable porous receptacle, the fusible oxide sinks into this containing vessel, in either case the oxidation of the lead affords a means of separating it from precious or inoxidisable metals if any were originally present in the lead. The above fact has been known from remote antiquity, and the early Jewish writers allude to it as old and well known. They clearly show, for instance, that lead can be removed from silver by being "consumed of the fire," while the silver is not affected That the Greeks knew and practised the method is abundantly proved, if only by certain specimens of gold and silver now in the adjoining museum, which were recently discovered by Dr. Schliemann The Arabians investigated the subject, for passing to Geber,[3] the greatest of the early chemists (he died in 777), we find a remarkable account of cupellation, he also describes the conversion of lead into a fine powder by calcination with much clearness, and he noticed the fact that after calcination the mass has "acquired a new weight in the operation." I think his subsequent observations on the reduction of altered metals from their "calxes" show that he knew the weight to be increased; in any case it is interesting to remember that his work was in a sense quantitative He moreover was cognisant of the fact that two different substances may be produced by heating lead in air, and he assumed that "in the fire of calcination a fugitive and inflammable substance is abolished." The alchemists refer continually to the subject, and "deliver themselves," as Roger Bacon said, in his "Speculum Alchimæ," "in the enigmas and riddles with which they clouded and left shadowed to us the most noble science" In the middle of the sixteenth century the truly accomplished metallurgist Biringuccio,[4] contemporary of Paracelsus and Agricola, seems to have been specially attracted by the phenomenon in question, and he remarks. "If we had not lead we should work in vain for the precious metals, for without its aid we could not extract gold or silver from the stones containing them. . . The alchemists also," he said, "make use of it in their operations, calcining it by itself or with other substances, but," he goes on to observe, "the calcination, conducted in a reverberatory furnace, is accompanied by a marvellous effect, the result of which should not be passed by in silence; for lead thus treated increases 10 per cent. in weight, and, considering that most things are consumed in the fire, it is remarkable that the weight of lead is increased, and not diminished." Although he subsequently gives evidence of much accurate knowledge of practical metallurgy, his views as to this particular phenomenon were hardly in advance of Geber's, but we may claim Biringuccio as an early metallurgist, who knew the facts, and recognised that they were theoretically important. It was not until nearly a century later (1630) that a French chemist, Jean Rey,[1] stated that the increase in weight came from the air. The problem attracted much attention in England, and it is not a little interesting that among the very first experiments recorded by our own Royal Society is a metallurgical series relating to the weight of lead increased in the fire on the "copels" at the assay office in the Tower, the account being brought in by Lord Brouncker in February, 1661.[2] [Subsequently, in 1669, John Mayo showed that the increase in weight of calcined metals was due to a "spiritus" from the air.[3] Boyle heated lead in a small retort,[4] and attributed the increase in weight, as Lemery also did,[5] to his having "arrested and weighed igneous corpuscles"[6]

I need hardly point out how important this calcination of lead was considered by those who defended the Phlogistic theory in regard to chemical change, a theory which, for more than a century, exerted so profound an influence on scientific thought. [As this theory originated with a metallurgist, Becker, it was considered at some length, and it was made evident that the main aim of chemical investigation down to the end of last century was the explanation of calcination, combustion, or oxidation, and that lead was especially useful in solving the problem]

I might perhaps add that the *absorption* of oxygen by molten litharge has furnished M. Ste. Claire-Deville,[7] a physicist and metallurgist, with an important step in the argument as to dissociation, and thus connects the history of the metal with the great advance on the borderland of chemistry and physics in modern times, to which I shall constantly refer.

The above remarks will, I trust, be sufficient to show that conclusions of the utmost importance in the history of chemical theory were based on a very ancient metallurgical process, but I have also selected lead as an illustration, because, in the gradual development of the knowledge derived in the first instance from its metallurgy, there is much that is typical of the mutual relation of theory and practice that still prevails

When Dr. Percy began his teaching, he considered at some length the kind of assistance that other sciences might be expected to render our subject, considered as a manufacturing art, and this at the time was necessary for two reasons,[8] first, because he was "able to adduce from his own observation several striking cases in illustration of the advantage of the application of science to practical metallurgy; and, second, because the practice of metallurgy, so far as relates to magnitude of operation, having been developed to an unparalleled extent in this country in the absence of specific public instruction on the subject, it was necessary to justify the providing of such instruction."

The absence of accurate knowledge on the part of those engaged in metallurgy was lamented as long ago as 1700, in an "Inaugural Dissertation of Pyrotechnical Metallurgy," delivered, on March 25 of that year, in the University of Magdeburg, no less a person than the great supporter of the theory of Phlogiston, George Ernest Stahl, presided, and the lecturer was

[6] I am indebted to my friend Prof Ferguson, M A, of the University of Glasgow, whose eminence as a historian of chemistry is well known, for several interesting additional facts in connection with the calcination of metals After referring to Eck (1489), Glauber (1651), and others, he writes "One of the most curious passages I know is in the 'Hippocrates Chemicus' of Otto Tachen, or Tachenius, a German who lived at Venice and published his book there in 1666 He describes how lead, when burnt to minium, increases in weight. This increase he ascribes to a substance of acid character in the wood used for burning, and then, by a very curious course of argument, based on the saponifying powers of litharge, makes out that lead is of the nature of or contains an alkali, which combines with the 'occult acid of the fat.' This is a curious anticipation of a very modern classification which brings lead into relationship with the alkalies and alkaline earths, as well as of Chevreul's investigations."

Fritschius, who said:[1]—"If in any part of the working of metals there is commonly more owing to experience than reason, truly it is in fusion or melting . . . nevertheless if the reason be asked why the business succeedeth well in this way but in another doth not succeed at all, you have no solid answer, but only that most general one, which is most commonly false, viz that one fire is stronger and another weaker, and so insufficient" It is just a century since Bishop Watson, Professor of Chemistry and Regius Professor of Divinity in the University of Cambridge, pointed out[2] that "the improvement of metallurgy and other mechanic arts dependent on chemistry might best be made by public establishment of an Academy, the labours of which should be destined to that particular purpose," and the School of Mines, thus foreshadowed, was established in 1851, its principal object being to "discipline the students thoroughly in the principles of those sciences upon which the operations of the miner and metallurgist depend"

Our honoured founder, Sir Henry de la Beche, in his Address at the opening of the School of Mines,[3] said:—"We still too frequently hear of practical knowledge, as if in a certain sense opposed to a scientific method of accounting for it, and as if experience, without that advantage, was more trustworthy than the like experience with it." Such remarks might, with truth, be made at the present day; but it should nevertheless be remembered that many metallurgical works are successfully conducted in this country by so-called practical men. I do not mean the kind of man so forcibly described by Mr Bramwell[4] as one "whose wisdom consists in standing by, seeing, but not investigating the new discoveries which are taking place around him . the aim and object of such a man being to ensure that he should never make a mistake by embarking his capital or his time in that which has not been proved by men of large hearts and large intelligence," nor do I mean the man who accepts no rule but the "rule of thumb", but I do mean practical men possessing technical knowledge of a high order, whose careful observation enables them to use the results of past experience in dealing with circumstances and conditions analogous to those they have met with before, and with which long practice has made them familiar It would be difficult to overrate the value and importance of such knowledge as theirs, and, when we remember the scale on which smelting and other operations are carried on, it will be obvious that this kind of knowledge can only be gained in the works, and not in the laboratory or lecture-room, for, however careful the metallurgical teaching here may be, it can only be practical in a limited sense At the same time it must be borne in mind that a man trained to scientific methods starts with the enormous advantage of being able to deal with circumstances and conditions that are new to him, and with which therefore he cannot be said to be "familiar." The technical skill that time and opportunity can alone give him will then rest on a solid basis. I repeat, however, that I am anxious at the outset to guard against undervaluing the teaching of experience unaided by reasoning that we should recognise as scientific; for it is only necessary to witness such operations as the roasting of a large mass of ore on the bed of a furnace, or the forging of many tons of iron under a steam hammer, to appreciate the value of the subtle skill of sight and touch on which success depends

I have thus ventured to trace the relation between scientific and technical men, as hitherto there have been misunderstandings on both sides, or, as Dr. Williamson so well observes[5]—"Men of detail do not sufficiently appreciate the value and usefulness of ideas, or of general principles, and men of science, who learn to understand and control things more and more by the aid of the laws of nature, are apt to expect that all improvements will result from the development and extension of their scientific methods of research, and not to do justice to the empirical considerations of practical expediency, which are so essential to the realisation of industrial success in the imperfect state of our scientific knowledge."

While it is no longer necessary to justify the scientific teaching of metallurgy, as Dr. Percy did, it is as important as ever that the true relation of Theory and Practice should be clearly understood. It rarely happens that a process can be transferred from the laboratory to the works without important modifications; and we must remember that metallurgy is a manufacturing art, and that, when the truth of a theory has been demonstrated, a dividend has to be earned, this would indeed often be difficult without the aid of the technical man. Practical men have, however, ceased to undervalue science, and the most practical body of men in the world, in the best sense of the term, the iron masters of this country, on whom its prosperity so largely depends, formed themselves ten years ago into an Iron and Steel Institute, many of the members of which possess high scientific attainments and are distinguished for scientific research

Let us turn, then, to the advice given us by those who are accustomed to deal with metals on a large scale Mr. I Lowthian Bell stated in his address as president of the Institute in 1873[1]—"If we would avoid the failure of what may be designated unscientific practice, or the failure of impracticable science, we must seek to combine commercial intelligence with a knowledge of those natural laws which form the only trustworthy groundwork of the complicated processes in which we are engaged."

Dr Siemens[2] said in 1877,—"It is not many years since *practical* knowledge was regarded as the one thing requisite in an iron smelter, whilst *theoretical* knowledge of the chemical and mechanical principles involved in the operations was viewed with considerable suspicion," and he adds, with reference to the teaching of the School of Mines and of a general Technical University —"But it must not be supposed that I would advocate any attempt at comprising in its curriculum a practical working of the processes which the student would have to direct in after-life. . . Let technical schools confine themselves to teaching those natural sciences which bear upon practice, but let practice itself be taught in the workshop and in the metallurgical establishment"

The president for 1879, Mr E. Williams, a most eminently practical man, and one of the founders of the prosperity of the great Cleveland iron district, urged[3] "educated intellectual young men, who now hang listlessly about the professions . . to break through the absurd old prejudice against seemingly rough work," in order that they may act as scientifically trained managers

I have thus appealed to authorities, because my own practical work has been mainly confined to a limited branch of metallurgy. I say limited, for although, on looking into the matter, I find, to my surprise, that I have during the last ten years been responsible for the fineness of 330 tons of gold and 740 tons of silver, this, though of a total value of forty-seven millions sterling, is a comparatively small bulk of metal, and the operations through which it passes are seldom complicated; but I am none the less convinced that in metallurgical works generally, as in a mint, the work can only be efficiently conducted by taking advantage to the utmost extent of the aid that science has to offer, a mint only differing from other works by the extraordinary care and vigilance which must be exercised to insure accuracy and avoid loss in dealing with the precious metals. Even this difference is less marked than formerly, and as attention to minute details is becoming more and more essential to the profitable conduct of works, my experience in this respect will be useful to you

As regards the actual training in the school, I believe that our utmost efforts should be devoted to giving the students a thorough acquaintance with scientific methods and metallurgical principles, furnishing them at the same time with as many well-ascertained *facts* as possible. Here I may perhaps be permitted to quote a few words from Prof Huxley's[4] recent address at Birmingham, as they bear so directly on our subject, he said, "What people call applied science is nothing but the application of pure science to particular classes of problems It consists of deductions from those general principles, established by reasoning and observation, which constitute pure science No one can safely make these deductions until he has a firm grasp of the principles; and he can obtain that grasp only by personal experience of the processes of observation and of reasoning on which they are founded"

In one important branch of metallurgy—assaying—the teaching in the School is thoroughly practical, and the operations you may in future be called upon to conduct will not differ from those taught in this laboratory. The teaching will, I am glad to say, be now specially entrusted to my friend Mr. Smith, the value of whose instruction in my own case I gratefully acknowledge.

It can hardly be questioned that until the School of Mines was established the metallurgical success and reputation of this country rested to a remarkable extent on the exceptional skill of its technical men. I think therefore we may fairly be asked to consider whether the metallurgical teaching of the School has been justified, and how far advance has been due to trained scientific thought.

Of all the metallurgical operations conducted in this country, those connected with iron are, of course, the most important. The production of pig iron alone in the United Kingdom has increased from two million seven hundred thousand tons in 1852 to six million two hundred thousand tons last year, a maximum slightly in excess of this figure having been reached in the year 1872. Now the Bessemer process, the first patent in connection with which was taken out in 1855, has reduced the cost of steel from 50*l.* to 6*l.* per ton, and has changed the whole aspect of the iron and steel manufacture; indeed, the success with which this process alone is conducted may almost be regarded as an index of our national prosperity. Notwithstanding the almost universal depression of trade during the last few years, the outturn of steel has been steadily increasing, and it is estimated that in 1879 this country produced nearly a million tons in the Bessemer converter, double the entire produce of the remainder of the world in the year 1870 by the same process.[1] The outturn of Bessemer steel in America has, however, advanced with still more rapid strides; for last year she actually produced, with far fewer converters, ninety-four thousand tons more than this country. It will be evident, therefore, that every improvement effected in this process is of truly national importance, and I would briefly refer to the greatest that has been introduced in recent years.

In 1855 the fact was established that pig-iron from the blast-furnace contains the greater part of the phosphorus originally present in the ore. Dr. Percy pointed out that phosphorus is not eliminated in a sensible degree in the Bessemer process, as it is in the old process of puddling, and he stated that if the Bessemer process is to be "generally applicable in this country, it must be supplemented by the discovery of a process of producing pig-iron sensibly free from sulphur and phosphorus, with the fuel and ores which are now so extensively employed in our blast-furnaces."[2] The problem, so far as it relates to the elimination of phosphorus, has received the attention of many of the first metallurgists in this and other countries,[3] but the practical application of basic linings in the Bessemer converter is the outcome of Dr. Percy's teaching; for Mr. S. G. Thomas was a student of the School of Mines, and his partner, Mr. Gilchrist, is an Associate. Mr. Snelus is also an Associate, and Mr. Riley long worked in the metallurgical laboratory. The process not only gives hope that it will be possible to utilise the large quantities of ore in the well-known Cleveland district, but is also widely practised with success on the Continent.[4] It is probable therefore that the large deposits of ore in the basin of the Saar, and those of Lorraine and Luxembourg, which in extent are equal to the Cleveland district, while containing a much greater amount of phosphorus, will now be available. During a recent visit to the Hoerde Works in Westphalia, where I witnessed the operation, Herr Massenez, the director, told me that 10,000 tons of "Thomas-Gilchrist" metal have already been produced there since the adoption of the process a few months ago.

I had intended to indicate the metallurgical work done by the more prominent men who have been associated with the school, but I found that it would not be possible, in the brief time at my disposal, to do justice to such as Bauerman, Dick, Gibb, Hackney, Matthey, Pearce, Riley, Willis, and others, whose labours have placed them so high in the ranks of English metallurgists. You will, however, as the course proceeds, have opportunity of becoming familiar with their names.

In referring to the past teaching of the school I must remind you of the importance of rigorous and minute inorganic analysis; and it is the more necessary that I should do so from the fact that the peculiar charm of organic research appears, as has been pointed out by Prof. Abel,[5] to lead the younger chemists to "under-estimate the value and importance, in reference to the advancement of science, of the labours of the plodding investigator of analysis." I am satisfied, however, that, if we bear the traditions of the chemical and metallurgical laboratories of the School of Mines in view, we are not likely to under-rate the importance of analytical work; and much conclusive evidence as to the value of the teaching of the past thirty years is afforded by the labours of the accomplished analysts who have from time to time worked under Dr. Percy's direction.

The direct influence of the School on the success with which metallurgy has been practised in this country has been most marked, and would alone afford an answer to the question whether the possession of high scientific attainments is generally advantageous to the successful conduct of metallurgical works. It must not be forgotten that our subject is constantly receiving valuable aid from branches of science other than chemistry, and this can hardly be better shown than by the growing importance of physical research in connection with metallurgical problems. I would incidentally remind you that it is the more important for us to consider this, because special attention was directed to the question in the evidence given before the Royal Commission on Scientific Instruction,[1] whose recommendations will, it is to be hoped, extend the influence of the School of Mines.

In connection with this branch of our subject a most prominent position must be given to the production of high temperatures, as it will be obvious that we have principally to consider the reactions of the elements when under the influence of heat. In the first half of the present century temperatures higher than the melting point of zinc were not known with any degree of certainty; but in 1856[2] M. Henri Ste. Claire-Deville pointed out that chemistry at high temperatures, that is to say, up to the blue-white heat at which platinum volatilises and silica fuses, remained to be studied. Since then, in conjunction with M. Troost, he has given us certain fixed points, such for instance as the boiling points of cadmium and zinc, and Deville's researches on dissociation have entirely modified the views generally entertained in regard to the theory of combustion. Indeed we owe so much to this illustrious teacher, that the best homage we can offer him will be to work in the directions he has indicated. M. Stas has proved that it is perfectly easy to distil even large quantities of silver from one lime crucible to another,[3] a fact which has been taken advantage of by Mr. Lockyer and myself in some experiments on the absorption-spectra of the vapours of certain metals at high temperatures.[4]

As regards scientific advance of a more essentially practical character, the gradual discovery of the fact that in certain cases fuel can be best employed if it be previously converted into gas, and the recognition of the advantages to be derived from a preliminary heating of the gases and the air, has led to the wide adoption of the regenerative system, by which the waste heat of the furnace is utilised for heating the incoming air or combustible mixture of air and gas necessary to effect the required operation. Dr. Siemens has thus shown us how to economise fuel to a vast extent, it being now possible to produce a ton of steel by the use of 12 cwt. of small coal instead of three tons of coke required to melt it in the old form of furnace. By the command of high temperatures, moreover, he has developed new processes in the metallurgy of iron, which are resulting in the replacement of the old "cinder-mixed" wrought iron by "cinder-free" ingot iron and steel.[5] The degree of heat attainable by the regenerative furnace is, however, limited to the temperature of dissociation of carbonic acid and aqueous vapour, so that the temperature never can exceed about 2600° C.; but during the present year[6] Dr. Siemens has employed the far greater heat of the electric arc for the fusion of steel and platinum.[7] Bearing in mind the interest excited by recent experiments on the effect of intense heat on bodies now considered to be elementary, we may expect physicists to look to us for aid in developing the methods of employing high temperatures.

The essential difference in the properties of certain alloys produced by a small difference of composition brings me to one very distinctive feature of metallurgy, the enormous influence

[7] Figures convey but little impression as to such high temperatures, but it may be mentioned that Dewar has given 7000° C. as approximately the temperature of the electric arc (Brit. Assoc. Rep. 1873, p. 466), and, according to Rossetti, the true temperature of the sun can hardly be less than 10,000° C. or more than 20,000° C.—*Phil. Mag.* [5], vol. viii. p. 550 (1879).

exerted on a large mass of metal by a trace of another metal or metalloid—that is, by a quantity so small that it appears to be out of all proportion to the mass in which it is distributed.

I think it may safely be asserted that in no other branch of applied science has the operator to deal with quantities that are at once so vast and so minute; and the course will not have proceeded far before you will recognise this fact.

It may be that the trace to be extracted is alone of value—as, for instance, the few grains of gold that can be profitably extracted from each ton of a material, which, though containing only one part of gold in five millions by volume, is thereby entitled to be regarded as an auriferous deposit that can be profitably worked; or it may be the minute percentage of a metalloid which must be extracted in order that the physical properties of a large mass of metal may not be entirely altered.

[Numerous instances of the influence of small traces of metals and metalloids, including the following, were then given —]

In 1866 Graham showed,[1] by experiments with which I had the privilege of being connected, that the presence of occluded gases in metals often exerts a marked influence on their molecular structure. In the case of iron he urged that metallurgists should study the effects of occluded gases, more especially carbonic oxide, the weight of which, according to his experiments, could not exceed the $\frac{1}{10}$ per cent. of the weight of iron in which it was present The significance of such facts is now under consideration by a Committee of the Institution of Mechanical Engineers,[2] and the question of the presence of gas in steel, either occluded or retained in the form of bubbles, is further being investigated by Chernoff,[3] Muller,[4] and others.

M. Nyst, of the Brussels Mint, has lately found that the presence of $\frac{15}{100}$ per cent of silicon in standard gold will so affect its molecular grouping as to render it possible for a thin strip to bend by its own weight, as zinc would, in the flame of a candle.

The growing importance of physical research in connection with metallurgy is shown by the fact that physical methods are now constantly appealed to by those interested in metallurgy, more especially in the case of iron and steel. We are told, for instance, that the hardness of steel may be correctly inferred from a numerical determination of its coercive force,[5] it is sought to establish the actual nature of the change in the mode of existence of the carbon in steel that accompanies hardening by determining its thermo-electric properties,[6] and the hope is held out[7] to us that the time will soon come when boiler-makers will electrically test their plates, possibly by the aid of the induction-balance, just as they now test them for ductility and tenacity I can only add the expression of a belief that this powerful weapon of molecular research which Prof Hughes has given us will yield good results in the hands of some of you

The results of mechanical tests are also of the highest importance. Not long since the appearance of the fracture of a sample of metal was considered to afford trustworthy and sufficient evidence as to its nature and properties, but such rough methods have given place, in the hands of Kirkaldy and others, to the rigorous physical and mechanical investigation to which metals must now be submitted as a matter of ordinary routine. The results, tabulated or plotted into curves, which mark the influence of each constituent or impurity, form permanent records of the greatest value[8]

It has only been possible for me to indicate the more important conditions affecting the successful practice of metallurgy I have traced the relation between technical and scientific workers, but there is yet another condition of somewhat recent growth. The enormous scale on which operations are now conducted renders it more necessary than formerly for those engaged in metallurgical enterprise to seek the aid of capitalists. The result is that a large share in the control of many important works falls to the non-scientific members of the Board of Directors, men of high commercial ability, but whose knowledge of the importance of scientific work is necessarily limited. It is true that they may recognise the necessity for scientific aid in the works with which they are connected, but they are too often unconscious of the labour and difficulty that are involved in the attainment of accurate scientific knowledge. I am convinced, however, that facts are gradually compelling them to recognise that the value of a metal may entirely depend on whether it does or does not contain a trace of impurity, and that the exact method of treatment to be adopted depends much on the character of the materials employed, they will therefore examine more carefully than they have hitherto done the qualifications of men to whom important duties are entrusted, and will insist that the services of only adequately trained metallurgists shall be secured.

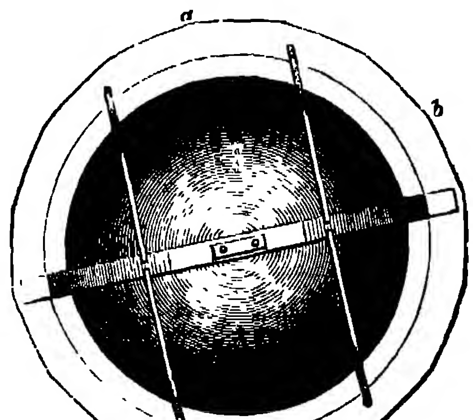
I shall have to direct your attention to the minute care with which details affecting commercial interests are now investigated,[1] and your success will further depend on the facility with which you are able to use the "tools of thought" furnished by chemistry, physics, and mechanics Whether you will ever possess the tact and judgment necessary to direct such works as Dowlais with an army of ,10,000 people, obviously depends on personal qualifications which I can but little influence.

I venture to hope that you will, by original research, add to the general advance of science, for, as the late Prof Clifford has reminded us, what have often proved to be the most useful parts of science have been investigated for the sake of truth, and not for their usefulness

Dr Percy found metallurgy practised in this country mainly as an empirical art He may well feel, to borrow the words of an old writer, that in his hands "the business of metallurgy and essaying has not only been illustrated but also improv'd, amended, and enrich'd", for his works contain a record of its progress, his teaching and researches have secured it a scientific basis, and he has trained a body of scientific workers, in whose hands the immediate future of metallurgy to a great extent rests Bearing in mind how much the progress of our science means to England, I cannot but be conscious that, in attempting to continue this work, I undertake a grave responsibility.

ON AN EXPERIMENTAL ILLUSTRATION OF MINIMUM ENERGY[1]

THIS illustration consists of a liquid gyrostat of exactly the same construction as that described and represented by the annexed drawing, repeated from NATURE, February 1, 1877, p 297, 298, with the difference that the figure of the shell is prolate instead of oblate The experiment was in fact conducted with the actual apparatus which was exhibited to the British Association at Glasgow in 1876, altered by the substitution of a



←— 7 INCHES —→

shell having its equatorial diameter about $\frac{9}{10}$ of its axial diameter, for the shell with axial diameter $\frac{9}{10}$ of equatorial diameter which was used when the apparatus was shown as a successful gyrostat.

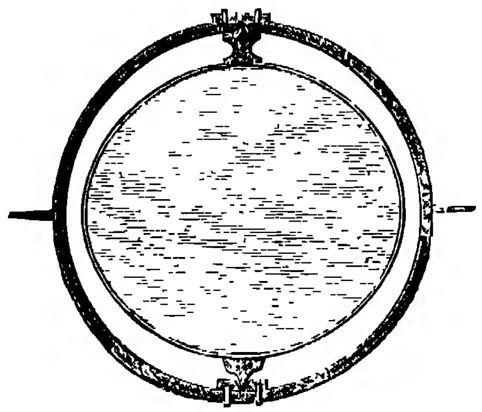
[1] By Sir William Thomson, F R S British Association, Swansea, Section A.

The oblate and prolate shells were each of them made from the two hemispheres of sheet copper which plumbers solder together to make their globular floaters. By a little hammering it is easy to alter the hemispheres to the proper shapes to make either the prolate or the oblate figure.

Theory had pointed out that the rotation of a liquid in a rigid shell of oval figure, being a configuration of maximum energy for given vorticity, would be unstable if the containing vessel is left to itself supported on imperfectly elastic supports, although it would be stable if the vessel were held absolutely fixed, or borne by perfectly elastic supports, or left to itself in space unacted on

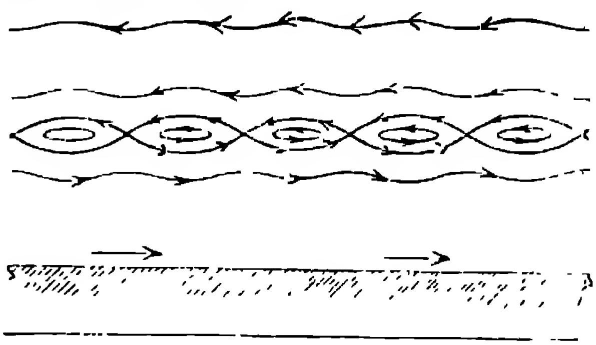


by external force; and it was to illustrate this theory that the oval shell was made and filled with water and placed in the apparatus. The result of the first trial was literally startling, although it ought not to have been so, as it was merely a realisation of what had been anticipated by theory. The framework was held as firmly as possible by one person with his two hands, keeping it as steady as he could. The spinning by means of a fine cord[1] round a small V pulley of ½-inch diameter on the axis of the oval shell, and passing round a large fly-wheel of 3 feet diameter turned at the rate of about one round per second, was continued for several minutes. This in the case of the oblate shell, as was known from previous experiments, would have given amply sufficient rotation to the contained water to cause the apparatus to act with great firmness like a solid gyrostat. In the first experiment with the oval shell the shell was seen to be rotating with great velocity during the last minute of the spinning, but the moment it was released from the cord, and when, holding the framework in my hands, I commenced carrying it towards the horizontal glass table to test its gyrostatic quality, the framework which I held in my hands gave a violent uncontrollable lurch, and in a few seconds the shell stopped turning. I saw that one of the pivots had become bent over, by yielding of the copper shell in the neighbourhood of the stiff pivot carrying disk, soldered to it, showing that the liquid had exerted a very strong couple against its containing shell, in a plane through the axis, the effort to resist which by my hands had bent the pivot. The shell was refitted with more strongly attached pivots, and the experiment has been repeated several times. In every case a decided uneasiness of the framework is perceived by the person holding it in his hands during the spinning; and as soon as the cord is cut and the person holding it carries it towards the experimental table, the framework begins, as it were, to wriggle round in his hands, and by the time the framework is placed on the table the rotation is nearly all gone. Its utter failure as a gyrostat is precisely what was expected from the theory, and presents a truly wonderful contrast from what is observed with the apparatus and operations in every respect similar, except having an oblate instead of a prolate shell to contain the liquid.

[1] Instead of using a long cord first wound on a bobbin, and finally wound up on the circumference of the large wheel as described in NATURE, February 1, 1877, p. 297, I have since found it much more convenient to use an endless cord little more than half round the circumference of the large wheel, and less than half round the circumference of the V pulley of the gyrostat, and to keep it tight enough to exert whatever tangential force on the V pulley is desired by the person holding the framework in his hand. After continuing the spinning by turning the fly-wheel for as long a time as is judged proper, the endless cord is cut with a pair of scissors and the gyrostat released.

ON A DISTURBING INFINITY IN LORD RAYLEIGH'S SOLUTION FOR WAVES IN A PLANE VORTEX STRATUM

IN the paper in last week's NATURE under this heading by Sir William Thomson, the lower part of the illustration was inadvertently turned round at the last moment by the printer, the cut should stand as follows:—



SARGASSUM[1]

THIS paper opens with a discussion of the value of the species *Sargassum bacciferum*, the particular species of this genus which is well known as the Gulf-weed. The author considers that the floating plants to which this name has been given are simply fragments of many varieties or species of Sargassum, more particularly of *S. vulgare*. In support of this view he points out that, from the accounts of nearly all authors who have examined specimens, it appears that the lower part of the stem had been broken across, and that it is therefore fair to conclude that they belong to plants which are rooted under ordinary circumstances. This conclusion had been already arrived at by Rumphius, C. Agardh, Rennell, Humboldt, and more recently by G. von Martens, but of these writers Rennell and Humboldt are of opinion that the floating fragments continue to grow, and in this they agree with Thunberg, Meyen, and Harvey. Dr. Kuntze contends that there is not sufficient evidence forthcoming to establish the correctness of this view. He urges that, even admitting that some growth takes place, it is only temporary, and that it therefore affords no ground for regarding these as pelagic plants. The only other cases of growth of Fuci when floating are offered by *Macrocystis pyrifera* (Sir Joseph Hooker, "Flora Antarctica," vol. i.), and by *Fucus vesiculosus* (Mr. Moseley, "Notes by a Naturalist on the *Challenger*"), and doubtless Dr. Kuntze's objections apply to these also. The question naturally arises as to whether these floating plants are actively living, or are dying, or dead.

In the case of Sargassum Dr. Kuntze considers that their bright yellow colour is due to changes taking place, either preliminary to or in consequence of death, in the brown colouring-matter of the attached forms to which he believes the floating fragments belong. Mr. Moseley, however, is of opinion that this is the natural colour of these plants whilst living. It does not appear that any such difference in colour has been noticed in attached and floating specimens of Macrocystis or of Fucus, and this is a fact which is not in harmony with Dr. Kuntze's views respecting Sargassum. Again, the general observation that these floating Fuci have no reproductive organs offers a further difficulty which they do not explain. Dr. Kuntze endeavours to meet the difficulty by stating that he has found receptacles occasionally in free-swimming individuals, and he gives figures of two plants bearing them, but neither from the figures nor from his account of them is it possible to conclude with certainty that the bodies in question are really of a reproductive nature; and he explains the usual absence of these organs in the floating individuals by suggesting that the receptacles, being the most fragile parts of the plant, are the most readily destroyed, and further that, owing to the small number of air-chambers with which they are provided, they would sink on becoming detached. In this case, as in that of the colour, these explanations respecting Sargassum will only become valid when they are found to hold good of Macrocystis and of Fucus also. It is apparent that the

[1] "Revision von Sargassum und das sogenannte Sargasso-Meer." Von Dr. Otto Kuntze (*Engler's botanische Jahrbücher*, Bd. I. Heft iii., 1880) Leipzig, Engelmann.)

evidence offered in support of Dr. Kuntze's views is at present incomplete, and that further researches into the life-history of these plants must be made before these views can be generally accepted.

After an elaborate systematic revision of the genus, Dr. Kuntze goes on to discuss the Sargasso Sea He draws attention to the wide divergences which exist between the accounts given of it by different travellers Thus Humboldt and Maury speak of it as a mass of gulf-weed having an area of thousands of square miles, whereas others—Sir Wyville Thomson, for instance—describe it as consisting of small scattered patches. Dr Kuntze concludes that there is no reason for assigning a definite and constant area to it It appears that the patches of weed occur more frequently in the region of calms, but at times it is either absent or present only in small quantities even there. A wind blowing for a considerable time in one direction might, under certain circumstances, cause the aggregation of patches into a mass of some extent, such as is to be found, for instance, in the neighbourhood of the Bermudas in spring after the equinoctial gales, but even this would be but small when compared with Humboldt's estimate

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

OXFORD.—The following gentlemen have been nominated by the Vice-Chancellor as examiners for the Degree of Bachelor of Medicine In the first examination for M B. —S H. Schnetzler.—Practical study of marine zoology , the zoological station of Naples, by E Yung —Sixty-third session of the Helvetic Society of Natural Sciences, held at Brigue on September 13-15, 1880; Proceedings in the departments of Physics and Chemistry, Geology, Botany, Zoology and Medicine.

SOCIETIES AND ACADEMIES

LONDON

Linnean Society, November 4.—Prof. Allman, F.R S., president, in the chair —The session opened by Mr H. C. Sorby showing drawings of some British sea-anemones, with habitat on the upper fronds of long seaweeds in deep water , and he recorded having seen a solitary cream-coloured cetacean on the English coast —Mr. Arthur Bennett drew attention to a new British Chara (*C. stelligera*), remarkable for the presence of stellate bulbils on the stems.—Mr. E M. Holmes exhibited two marine algæ new to Britain, viz., *Dasya gibbesii*, from Berwick-on-Tweed, and *Ectocarpus terminalis* from Weymouth ; and also species of *Callithamnion*, with antheridia and trichophore on the same branchlet.—Prof. T. S. Cobbold exhibited a remarkable trematode from the horse. It was discovered by Dr. Sonsini at Zagazig during the Egyptian plague, with which outbreak, however, the parasite had no necessary connection The worm (*Gastrodiscus sonsinonis*) appeared to be an aberrant amphistome furnished with a singular ventral disk, whose concavity was lined with about 200 small suckers having a tesselated aspect In this respect its nearest approach was a worm infesting a genus of spinny finned fishes (*Cataphractus*) belonging to the Triglidæ. According to Prof. Leuckart's recent anatomical investigation, however, doubts are thrown on its amphistomoid affinities —Mr G F Angas showed the leaf of *Hermas gigantea*, an umbelliferous plant of the Cape used as tinder by the Hottentots —Mr E A Webb exhibited a monstrous bramble (*Rubus fruticosus*) with flowers represented by elongated axes covered with minute pubescent bracts and apices fasciated.—A communication by Dr G. Watt was read, viz , contribution to the flora of North-West India. The geographical features of the district are noted. He divides it into three areas the first range, Ravee-Basin, with magnificent forests of *Cedrus deodara* on its northern slopes, has on the southerly ones vegetation with an Indian facies, being barely outside the humid influence of the tropical rains of the plains , the second range, comprising Pangi, Lower Lahore, and British Lahore, has a flora altogether changed, dry short summers and snow-clad mountains giving a climate and plant-life of quite a different cast , the third range evinces still further change of flora, this assuming a Thibetan type Some 300 species of plants are noted, four being new.—A paper on the Papilionidæ of South Australia, by J. G Otto Tepper, was read The butterflies of this part of Australia are comparatively few in numbers, and sombre colours prevail thus seemingly in harmony with the surroundings of their habitat. The paucity of numbers the author attributes to the dryness of the climate. Notes on the habits accompany the descriptions of the species —Notes on a collection of flowering plants from Madagascar were read by Mr. J G Baker. The flowering plants are less known than the ferns from this interesting island ; two new genera are denoted, viz. (1) *Kitchingia*, belonging to the Crassulaceæ, a succulent herb with fleshy sessile leaves and large bright red flowers in lax terminal cymes , (2) *Rodocodon*, a liliaceous plant with red flowers and peculiar spurred bracts it comes between *Muscaria* and *Urginea* Thirty new species are described.—Messrs. Edw. Brown, H F Dresser, and T. P Pippe were elected Fellows of the Society.

Mathematical Society, November 11 —Mr. C. W Merrifield, F.R.S., president, in the chair.—The Treasurer's and Secretaries' reports were read and adopted.—After the ballot had been taken, the gentlemen whose names are given on p 614 of the last volume were declared duly elected as the Council for the present session —Mr S Roberts, F.R S , the new president, having taken the chair, Mr. Merrifield read his valedictory address, "Considerations respecting the Translation of Series of Observations into Continuous Formulæ "—On the motion of Prof Cayley, F R S., the address was ordered to be printed in the *Proceedings*.—Mr H M. Jeffery, F R S , then read a paper on bicircular quartics, with a triple and double focus, and three single foci, all of them collinear —Mr Tucker (hon. sec) communicated parts of a paper by the Rev. C. Taylor, further remarks on the geometrical method of reversion.

Geological Society, November 3.—Robert Etheridge, F R.S , president, in the chair —Bernard Barham Woodward was elected a Fellow of the Society.—The President announced that the original portrait of Dr William Smith, painted by M. Fourau in the year 1838, had been presented to the Society by Mr William Smith of Cheltenham.—The following communications were read :—On the serpentine and associated rocks of Anglesey, with a note on the so-called Serpentine of Porthdinlleyn (Caernarvonshire), by Prof. T. G. Bonney, F R S , Sec G.S. Several patches of serpentine are indicated on the Geological Survey map on the western side of Anglesey, near Tre Valley Station, and a considerable one on Holyhead Island, near Rhoscolyn. These really include three very distinct varieties of rocks : (1) compact green schistose rocks, (2) gabbro, (3) true serpentine. The author described the mode of occurrence of each of these, and their relations, the serpentine being almost certainly intrusive in the schist, and the gabbro in the serpentine. The microscopic structure of the various rocks was described in detail, especially of the last. It presents the usual characteristics, and is an altered olivine rock which has contained bronzite. One or two varieties are rather peculiar ; an ophicalcite and a compact chloritic schist containing chromite are also noticed

At Porthdinlleyn there is no serpentine, but a remarkably interesting series of agglomerates and (probably) lava flows of a basic nature, which may now be denominated diabases.—Note on the occurrence of remains of recent plants in brown iron ore, by J. Arthur Phillips, F.G.S. The fossilising ironstone described by the author occurs at Rio Tinto, in the province of Huelva, Spain, in close proximity to the celebrated copper mines of that name, where it forms a thick horizontal capping of a hill known as the Mésa de los Pinos. In this iron ore Dr Carruthers has identified the following vegetable remains:—Leaves and acorns of *Quercus ilex*, Linn , leaves and seed of a two-leaved species of *Pinus*, most probably *Pinus pinea*, Linn., the cone of *Equisetum arvense*, Linn., and a small branch of a species of *Erica*. There is also a well marked leaf of a dicotyledonous plant not yet identified. The plants are evidently all of the same species as are still found growing in Spain. The author attributes this deposit of ironstone to the decomposition, partly by organic agency, of ferruginous salts, derived from the oxidation of iron pyrites, which flowed into a marsh or shallow lagoon. Subsequently to this the valleys of the Rio Agrio and Rio Tinto were eroded, leaving the Mésa de los Pinos with its thick capping of iron ore.—Notes on the locality of some fossils found in the Carboniferous rocks at T'ang Shan, situated, in a north north-east direction, about 120 miles from Tientsin, in the province of Chih Li, China, by James W. Carrall, F G S , with a note by Wm. Carruthers, F.R S. The author described the locality from which he obtained some plant-remains of apparently Carboniferous age, and stated that mining operations had been carried on by a Chinese company in the district since the year 1878 Several seams of coal occur, varying in thickness from 11 inches to 6 feet Mr. Carruthers stated in a note that the specimens submitted to him belong to a species of *Annularia*, probably *A. longifolia*, Brough, abundant in the British coal-measures, and found both on the Continent and in North America.

PARIS

Academy of Sciences, November 8 —M. Edm Becquerel in the chair —The following papers were read —On the heat of formation of dimethyl, and on its relation with the methylic and ethylic series, by M. Berthelot —Researches on the Upper Cretaceous of the northern slope of the Pyrenees, by M Hébert.—Observations on phylloxera, by M Henneguy. From over three years' observations he is quite convinced that vines not attacked may be saved, and those which have not suffered too much be restored Vine growers have three efficacious modes of treatment: sulphocarbonates, sulphide of carbon, and submersion But the treatment must be repeated each year (at least for a time), and must extend over the whole vineyard. To destroy the winter egg in the bark, decortication and treatment with sulphide of carbons has proved good , also application of flame to the stock with a "pyrophore" (the latter is more effectual than application of boiling water, also easier and more economical). The spontaneous recovery of seemingly dead vines is only temporary , new roots form after abundant rain, and supply sap for fresh shoots. If the insects (which persist) be destroyed before they reach these roots, the vine may quite recover —Observations on the influence of last season on the development of phylloxera , on insecticides, by M. Boiteau August and September were so rainy as to be very unfavourable to the insect. Most of the vines that still exist will be saved. Sulphide of carbon is largely used by all kinds of proprietors. Among other directions as to its use, he says, the quantity per square metre should be 15 to 20 gr.—Preparation of a new alimentary substance, *nutricine*, by M. Moride Raw meat, freed from bones and tendons, is passed into suitable machines with nitrogenised alimentary substances (bread, *e g*), which absorb its water, and form perhaps organic combinations with it. The whole is dried in air or a mild stove, then pulverised and sifted The powder got is grey or yellowish, and has an agreeable taste. With albumen, fats, or gummed water, solid cakes or cubes may be made of it, to be afterwards divided for soups, sauces, &c. The substance is very nutritive, and keeps indefinitely if not exposed to moisture or too great heat.—The Secretary stated that a great many applications had been made for seeds of the vines of Soudan. M. Lécard has published a *brochure* on this vine, and is collecting all the seeds he can to send home.—On algebraic equations; examination of the propositions of Abel, by M. West.—Researches on the transformation of oxygen into ozone by the electric *effluve* in presence of a foreign gas, by MM. Hautefeuille and Chappuis. Even a very little chlorine hinders the transformation, and when introduced destroys ozone previously formed. Nitrogen occasions a larger transformation than if the oxygen were unmixed, and had the same pressure as in the mixture. The formation of ozone in presence of hydrogen is greater than in that of nitrogen. With fluoride of silicium a large proportion of ozone is formed (the *effluve* becoming a luminous rain of fire). The authors theorise on these results.—Action of chlorine and hydrochloric acid on chloride of lead, by M. Ditte.—On the combinations of ammonia gas with chloride and iodide of palladium, by M. Isambert. The tensions of dissociation are weaker at the same temperature the greater the heat of combination.—On the formation of chloroform by alcohol and chloride of lime; equation of the reaction and cause of the liberation of oxygen manifested, by M. Béchamp. *En résumé*, the chloroform is produced without liberation of gas; the swelling is due exclusively to the chloroform, which is in a medium the temperature of which is higher than its boiling point, and to the tension of its vapour; the gaseous liberation only commences when it has completely distilled, and the temperature rises so as to reach that which is necessary to make the mixture of chloride of lime and water boil.—On the organisation and the development of the Gordians, by M. Villot.—M. de Treux described a bolide observed at Amiens on November 2, at 4 58 p m. Its diameter seemed about a sixth of that of the moon. Visible 10 to 15 sec the bolide was successively blue, yellow, and red , bright sparks being given out at each change of colour.—A geological map of Spain, by M. de Botella, was presented.

VIENNA

Imperial Academy of Sciences, November 4.—On the theory of so called electric expansion or electrostriction, by L. Boltzmann.—Measurements of co-vibration for the case of strong deadening, by C Laske.—On cells and intermediate substances, by S. Stricker.—The psychic activity of the coating of the brain, considered from a physiological standpoint, by L Schneeder.—Description and sketch of a steerable balloon, by W. Bosse.—On mesitylendisulpho-acid, by J Barth and T Herzig.—On the absorption of solar radiation by the carbonic acid of our atmosphere, by E. Lecher.—On some properties of the capillary electrometer, by J. Hepperger.

November 11 —On the Tsubra deer (*Cervus Ludorffii*, Bohlan), by L. T Fitzinger.—On the question as to the nature of galvanic polarisation, by F. Exner.—On the latent heat of vapours, by C. Puschl.—Theory of acceleration-curves, by F. Wittenbauer —On derivatives of cinchonin acid and of chinolin, by H. Weidel and A. Cobenzel —On croton-aldehyde and its derivatives, by A. Lieben and T. Yeisel.—On reduction of croton chloral, by the same.

SULPHURIC ACID AND ALKALI

On the Manufacture of Sulphuric Acid and Alkali. By George Lunge, Professor of Technology in the Zurich Polytechnic School, formerly Manager of the Tyne Alkali Works, South Shields. Vol. ii. (London: Van Voorst, 1880.)

THIS volume forms a fitting sequel to the first volume of Prof. Lunge's valuable work (noticed in NATURE, vol. xx. p. 263) on the alkali manufacture. The praise we bestowed upon the earlier volume may without stint be applied to this. Clearness and conciseness in style remarkable in a foreigner, accuracy and fulness in the description of both old and new processes, and admirable woodcuts of apparatus and manufacturing plant, constitute the chief merits of this by far the best treatise extant on the most important branch of chemical industry. The value of works on technical science, as well, we may also add, of the teaching of such subjects, depends not only on a sound knowledge of the scientific principles upon which the manufactures are based, but likewise upon a thorough acquaintance with technical minutiæ and the special details of construction and operation, the due observation of which is necessary for the manufacturer's success. Either one of these conditions may be fulfilled by a host of authors, but to find both fully developed, as is the case with Prof. Lunge, is rare. Manufacturers themselves, many of whom may be fully competent to the task, are, for obvious reasons, not given to make known the details of their successful manufacture. Nor is the professional chemical engineer likely to do more than describe the most common and well-known processes. Dr. Lunge enjoys the great advantage of having had manufacturing experience, if not along the whole line, at least over a very large portion of his subject; and to this he now adds that of a position in which every motive urges him to impart his knowledge unreservedly to his readers.

A criticism worth having of a book like the one under review should by good rights imply a knowledge of manufacturing detail at least comparable with that of the author. To this the present writer can lay no claim, whilst mere indiscriminate praise is a mode of treatment to which he would not subject the readers of NATURE, either for their sake or for his own. In order therefore to find out how far this work really teaches what it professes to teach, how far it is abreast of the improvements of the day, and how far it expresses a sound opinion on vexed trade questions such as "open" as against "closed" salt-cake roasters, or as Hargreaves salt-cake process as against the old Leblanc's process, the writer has called to his assistance his friend and former pupil, Mr. John H. Crossley of Widnes, in whose ability in both the theoretical and practical side of the subject he has the greatest confidence, and to whom he is indebted for an opinion on these questions.

The opening chapters of the volume are devoted to a discussion of the various methods of making salt-cake or sodium sulphate the first great step in the production of alkali from common salt. It is a fact worthy of note that although Leblanc's process had been in successful work in France from the year 1797, seventeen years elapsed before this was taken up in England at Walker-on-Tyne by Losh. This may be perhaps accounted for by the war then raging by which communication between the two countries was almost entirely cut off, but especially because of the high war duty on salt, which in 1805 amounted to no less than 30*l*. per ton, and which existed up to the year 1823! This may be regarded as the year of birth of the manufacture on a large scale, and in this year James Muspratt, whom we are glad still to be able to salute as the veteran founder of the alkali trade, erected works at Liverpool, where common salt was decomposed with sulphuric acid and the Leblanc process carried out completely. The difference in cost of production in the early part of the century and in recent years is seen by the fact that in 1814 soda crystals cost 60*l*. per ton, whilst in 1861 the price was 4*l*. 10*s*.

Dr. Lunge goes into the question of "Close" *versus* "Open" salt-cake roasters pretty fully, but deriving his practical experience from Newcastle, where open furnaces are almost exclusively employed, it is not surprising to find a leaning towards the latter form betrayed in spite of his attempt to place the matter before his readers in an impartial manner. One of his arguments in favour of open roasters is that stronger sulphate is obtained by their use; he says (p. 93) "Owing to the higher temperature of an open roaster it is much easier to calcine the salt-cake and to decompose the common salt completely. In blind furnaces this can only be obtained by employing a large area and consequently a very thin layer of material and spending a good deal of time over the calcining process. This of course is much easier with furnaces possessing two muffles to one pan."

Against this fact it may be mentioned that though the Lancashire close roasters are certainly built larger than the Newcastle open ones, a much larger charge is worked, and many works regularly turn out salt-cake testing above 97 per cent., and this too in furnaces with one muffle only, the double form he speaks of and figures on pp. 72 and 90, being certainly represented in practice by one or two isolated specimens only.

Dr. Lunge (p. 116) gives 14–15 cwt. as usual charges of salt for close roasters, but as much as 18 cwt. are frequently worked at one operation. In this same question the author hardly gives due prominence to the "Plus Pressure" system, which is now doing good work with regard to close roasters. Probably the appendix to be published with vol. iii. will deal with this.

The description (pp. 115–125) of the actual working of a salt-cake furnace is very good indeed.

Chapter IV., on Hargreaves' Process, is also excellent, and is probably the best description extant; the only fault that could be found is that the figures show a double line of cylinders separated by an arch, the idea being to allow of having a drawing-door on each side of the cylinders. This however is not by any means compensated for by the greater loss of heat by radiation. Only the earlier plants are built this way, the more modern erections having the cylinders built back-to-back so as to form one solid block.

Dr. Lunge wisely refrains from much speculation as to the future of this most ingenious process. "If we are to

pronounce finally upon the prospects of this process," he says (p. 158), "we shall not find this quite an easy task. A few years ago English alkali-makers had such a high opinion of that process that no new vitriol chambers were built, and the question was discussed whether it was more worth while to work down the existing chambers, or to defray the cost of the new plant at once. Afterwards a less sanguine opinion gained ground, and it seemed as if Hargreaves's process would again be put into the background." At the present moment the writer believes that the outlook for the Hargreaves process is more favourable than ever

Chapters V and XII, on the Cost of producing Sulphate and Soda-ash, can only serve to give an approximate idea of the matter. The exact cost involved is not readily imparted by manufacturers, and is moreover governed by local circumstances, such as the current price of labour, &c.

The latter half of the volume is concerned with the second stage in the manufacture of alkali known as the black ash process In this the salt-cake is heated with limestone and coal, the resulting carbonate of soda being removed by lixiviation from the insoluble alkali makers' waste The first part of the chapter on Hand Furnaces appears to be very complete, and the figures on the plate facing p 386 are correct and well-drawn This can hardly be said of that portion relating to the modern revolving furnaces, this is probably the weakest part of the book, the author having apparently had no practical experience on this point. Figures of two revolvers are given; of these Fig 182 may be said to represent a fairly good design, though one single wide evaporating pan is considered more convenient for repairs than two narrow ones. As regards the speed of revolution (p 411) Dr. Lunge is a little out He says the revolver gearing must be capable of giving speeds of one revolution in four minutes to five revolutions in one minute, "usually the highest velocity does not exceed one revolution per minute" Those figures are not correct for the present style of working Revolvers should be able to go a good deal slower, but speeds as high as seven to eight revolutions per minute should always be possible, especially when working the Pechiney-Weldon process, when the after charge has to be very well and rapidly mixed through the rest. This can hardly be obtained when the large spin-wheel on the revolver is worked from a worm-wheel as Dr. Lunge describes, a pinion-wheel should be used. The author (p 406) says, "Leaving aside the older constructions of revolving furnaces, we shall only describe two of the most modern" The first of these has been spoken of above, the second, figured pp 414 and 415, a revolver fired by gas, was erected at one works only in 1870, and was found to be a failure, after running a year or two it was entirely reconstructed to burn fuel. Since then the mechanical bogies and engine gearing have been completely altered, so that the figures can hardly be said to represent one of the "most modern constructions"

Regarding chimney power Dr. Lunge says (p. 412) that usually every two revolvers have a chimney 6 feet diameter and 100 feet high to themselves. This is certainly not sufficient for the most economical working; to stint a revolver of draught is a serious mistake.

On another point in the black-ash process Dr. Lunge's opinions do not tally with those of Lancashire manufacturers. A few years ago Mr. Mactear of St Rollox proposed a plan of adding from 6 to 10 per cent. of lime to the black-ash in excess of that usually worked. This apparently simple process was believed by some likely to work wonders, and statements were made as to the actual gain of many thousands of pounds per annum in a single works by its adoption. Dr. Lunge gives more credit to this than some of our Lancashire friends seem inclined to do.

The remaining processes in the great suite of chemical changes involved in the alkali trade are as thoroughly discussed by Dr. Lunge as those which have now been noticed. Divergent views concerning many details of these may doubtless be held by various manufacturers, but all will agree in the opinion not only that this is an excellent book, but that it would be very difficult for any one to write a better one.

H. E. Roscoe

THE FLORA OF PLYMOUTH

Flora of Plymouth an Account of the Flowering Plants and Ferns found within Twelve Miles of the Town, with Brief Sketches of the Topography, Geology, and Climate of the Area and History of Local Botanical Investigation. By T R. Archer Briggs, F.L S With Map 8vo, pp. xxxv. and 432. (London. Van Voorst, 1880)

THIS is a model local flora Mr. Briggs is well known as one of the most experienced and trustworthy amongst the botanists who have made a special study of British Phanerogamia He has established a claim upon the gratitude of his fellow-workers by acting for several years as the honorary distributor of their Exchange Club, and in this capacity has received and sent out many thousands of specimens The present work is the result of the rambles of twenty years, and as he has restricted its limits to a radius of twelve miles from the town, the whole of the district has been within walking distance of his home, and it is probable that there is no tract in Britain of which the plants have been worked out and placed on record in such a thorough and exhaustive manner. A radius of twelve miles from Plymouth includes a great variety of soil and situation There are the maritime plants of the seashore and the tidal reaches of the Tamar and its affluents. Inland there are in the low country besides the stream-sides, meadows, and cultivated fields, plenty of woods and deep shady lanes with high banks and thick hedgerows, and the twelve miles radius reaches to a height of 1,700 feet on Dartmoor, and includes a considerable space of open uncultivated heathy and swampy ground. The district is not rich in limestone nor in ponds, but except in the plants which affect these two kinds of station there is full scope so far as situation goes to suit all their varied requirements in habitat.

Out of the 1,680 species enumerated in the last edition of the London Catalogue 873, or considerably more than half, are found within the radius covered by this book. Out of these 728 are natives, and the other 145 more or less certainly introduced by human agency.

It is interesting to have an area so far west in the island so thoroughly worked out, and certainly one of the most instructive points in connection with the matter is to note which British plants fail to reach and become very rare within the area. Taking the species according to their types of distribution as classified by Mr. Watson in the fourth volume of his "Cybele Britannica," and adopting the more stringent scale of species-limitation which he there follows, we find that out of 1,425 British species 764 grow in the neighbourhood of Plymouth. The 120 species of Watson's highland or extreme northern type and the 49 local or doubtful species are not represented here at all. Of the eighty-one species of his Scottish type we get only 5, and out of the 37 species of his intermediate type only 3 enter into the Plymouth area. So that the boreal element of the British flora, 238 species, is represented at Plymouth only by 8 species, such plants as *Rubus saxatilis*, *Gnaphalium dioicum*, *Polypodium Phegopteris*, *Polypodium Dryopteris*, and *Lycopodium Selago* lurking in very small quantity in the recesses of Dartmoor. Of Watson's 70 Atlantic or specially western species Plymouth has 36; of Watson's 127 Germanic or specially eastern species Plymouth has only 16, of the 532 species spread almost universally through Britain Plymouth has 484. Perhaps the most noteworthy point of all is that of Watson's 409 plants of the English type of distribution, plants spread widely through England, but running out in a northern direction north of the Humber and in the Scotch Lowlands, Plymouth gets only 220, or little more than half. Amongst the absentees in widely-spread English plants, for instance, are the common Forget-me-not (*Myosotis palustris*), the Mistletoe, *Genista tinctoria*, *Veronica Anagallis*, *Glyceria aquatica*, and *Scirpus lacustris*; and amongst the great rarities the common harebell (*Campanula rotundifolia*), the cowslip, the common butter-bur, *Hieracium boreale* and *vulgatum*, and some of the common south-country weeds, like *Solanum nigrum* and *Mercurialis annua*, which round about London are exceedingly plentiful. In the critical genera of British plants Plymouth is rich in rubi and roses, very poor in willows and hieracia. Amongst the rarities of the neighbourhood are *Polycarpon tetraphyllum*, *Eryngium campestre*, *Pyrus Briggsii*, a curious pear with fruit like that of a small crab-apple, *Physospermum cornubiense*, and two species of *Hypericum*, *bæticum*, and *linariifolium*, and it produces some curious hybrid epilobia and rumices.

The area is divided into five districts, founded on river-drainage, two of which are in Cornwall and three in Devonshire, and under these the special localities of the species are carefully traced out, the abundance in which each occurs being particularised, and the claims of each to be regarded as wild being in all doubtful cases carefully investigated.

As stated in the title, the book includes a map and short sketches of the climatology and geology of the district, and of the progress of botanical investigation within its bounds from the days of Lobel and Parkinson down to the present day. We can recommend it with confidence to all our readers who are interested in geographical botany as one of the most complete, conscientious, and interesting works of its kind that have ever appeared.

OUR BOOK SHELF

Peruvian Antiquities. The Necropolis of Ancon in Peru. A Series of Illustrations of the Civilisation and Industry of the Empire of the Incas. Being the Results of Excavations made on the Spot. By W. Reiss and A. Stubel. (London: Asher and Co., 1881.)

A FIRST instalment now lies before us of this magnificent undertaking, which, if fully realised, bids fair to rival in scientific interest and typographical splendour Lord Kingsborough's great work on Mexican Antiquities. Reserving a full notice for a later stage of the project, it will suffice here briefly to indicate its main features, and direct attention to its paramount importance for antiquarian and ethnological studies. The authors, who have lately returned from South America laden with archæological treasures of all kinds, have been encouraged by the munificence of the directors of the Berlin Royal Museum to place the results of many years' diligent research at the disposal of the public. Under the general heading of "Peruvian Antiquities" the publishers, Messrs. Asher and Co., of Berlin and London, propose to issue simultaneously in English and German a series of folio volumes illustrating the whole field of the ancient Quichua-Aymara culture, such as it existed at the time of the Spanish invasion. The publication will spread over a number of years, each volume appearing in separate parts varying in number according to the nature of the subject. Each part will contain a number of chromolithographic engravings with corresponding pages of explanatory text. These illustrations, which of course are the great feature of the work, will be produced in the most finished style of modern typographic art, and will consist of perfect facsimiles either in natural or reduced size of every conceivable object associated with the ancient civilisation of the Incas. The series begins with a volume devoted entirely to the "Necropolis of Ancon," now an obscure watering place and fishing village on the Peruvian coast, a little north of Lima, but in pre-Spanish times evidently the centre of a thickly-peopled district that had long been occupied by a settled population. The "finds" made in the mummy graves of this burial-place are of extraordinary archæological interest, illustrating in the most vivid manner every aspect of the social and domestic life of the ancient Peruvians. The volume is to be completed during the course of the ensuing two years in ten uniform parts, as above described, and to judge from Part I., which has just appeared, it is likely to prove of the utmost value to the antiquary and ethnologist. But our remarks on all details must be postponed till this volume is completed. The English text has been entrusted to Mr. A. H. Keane, whose special knowledge of the subject must ensure accuracy in the descriptive and explanatory part of the work.

Exposé Historique concernant le Cours des Machines, dans l'Enseignement de l'École Polytechnique. 23 pp. (Paris: Gauthier-Villars, 1880.)

THE council for the improvement of the course of study at the Polytechnic School has for some time had under consideration a revision of the *Programme d'Instruction* of the two years' course, and at different times, for instance in 1865, steps have been taken with a view to their improvement, but, according to this pamphlet, different circumstances, especially in 1870, have deferred the realisation of such schemes. Upon such a wide subject our author does not venture, but he confines himself merely to that part which relates to the *Cours de Machines*. We are indebted for this very interesting and full historical sketch of the matter from the very foundation of the school to the veteran geometer, M. Chasles.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.*]

The Editor urgently requests correspondents to keep their letters as short as possible. The pressure on his space is so great that it is impossible otherwise to ensure the appearance even of communications containing interesting and novel facts.]

Fertilisation of Yucca

IN NATURE, vol. xxii. pp 606, 607, appears a letter to which my attention has only to-day been called—signed E. L. Layard—on the subject of the fertilisation of yuccas successfully introduced and cultivated in New Caledonia.

The writer shows himself to be under some misapprehension as to the generic characters and appearance of the insect which is generally credited with the fertilisation of these plants in their native country. The moth of the genus *Pronuba*, to which he refers, is not a "large moth having yellow under-wings." Although a common species belonging to the *Noctuidæ*, standing in our British lists under the genus *Triphæna* (Ochs), but included in Dr Staudinger's European Catalogue in the genus *Agrotis* (Ochs), is distinguished by the specific, not generic, name *pronuba* (Lin.), as well as by the characteristic appearance to which your correspondent evidently alludes.

The genus *Pronuba* (Riley) was founded for the reception of *Pronuba yuccasella* (Riley) (see *Proceedings* Acad Sci Missouri, ii pp 55, 333; *Report* Nox Ins Missouri, v 151, vi. 131, *Canadian Entomologist*, iv 182, Hayden's *Bulletin* of the U S. Geological and Geographical Survey, iii. 121-141, &c), which has also been described by Prof Zeller in the *Verhandlungen der zoologisch-botanischen Gesellschaft in Wien*, 1873, vol xxiii. pp. 232, 233, under the name *Tegeticula alba*.

This small white moth, of which some varieties have a few black dots on the fore wings, belongs to the Lepidopterous group *Tineina* (Stn), possibly to the family *Hyponomeutidæ*. Prof Riley finds that the female, which has the basal joints of the maxillary palpi developed into a long curved tentacle furnished with spines, uses these appendages to collect and convey the pollen of the yucca to the tube of the stigma, which it could not otherwise reach, the eggs are then deposited, and the larva feeds upon the fruit, subsequently hibernating and becoming a pupa on the earth. It would be most interesting to ascertain whether *Pronuba yuccasella* (Riley) has been introduced with the yucca into New Caledonia, or whether any other insect, either indigenous or not indigenous to North America, has been found to take its place in carrying on the work of fertilisation. Prof. Riley considers the fact that yuccas introduced into the more northern portions of America have failed to produce seed may be attributed to the absence of *Pronuba*.

If Mr. Layard will direct his attention to this point he can scarcely fail to supply some valuable and instructive evidence bearing upon the subject. WALSINGHAM

Skin Furrows of the Hand

ALLOW me to contribute the information in my possession in furtherance of the interesting study undertaken by your Japan correspondent (vol. xxii. p 605).

I have been taking sign manuals by means of finger-marks for now more than twenty years, and have introduced them for practical purposes in several ways in India with marked benefit.

The object has been to make all attempts at personation, or at repudiation of signatures, quite hopeless wherever this method is available.

(1) First I used it for pensioners whose vitality has been a distracting problem to Government in all countries. When I found all room for suspicion effectually removed here, I tried it on a larger scale in the several (2) registration offices under me, and here I had the satisfaction of seeing every official and legal agent connected with these offices confess that the use of these signatures lifted off the ugly cloud of suspiciousness which always hangs over such offices in India. It put a summary and absolute stop to the very idea of either personation or repudiation from the moment half a dozen men had made their marks and compared them together. (3) I next introduced them into the jail, where they were not un-needed. On commitment to jail each prisoner had to sign with his finger. Any official visitor to the jail after that could instantly satisfy himself of the identity of the man whom the jailor produced by requiring him to make a signature on the spot and comparing it with that which the books showed.

The ease with which the signature is taken and the hopelessness of either personation or repudiation are so great that I sincerely believe that the adoption of the practice in places and professions where such kinds of fraud are rife is a substantial benefit to morality.

I may add that by comparison of the signatures of persons now living with their signatures made twenty years ago, I have proved that that much time at least makes no such material change as to affect the utility of the plan.

For instance, if it were the practice on enlisting in the army to take (say) three signatures—one to stay with the regiment, one to go to the Horse Guards, and one to the police at Scotland Yard—I believe a very appreciable diminution of desertions could be brought about by the mere fact that identification was become simply a matter of reference to the records.

And supposing that there existed such a thing as a finger-mark of Roger Tichborne, the whole Orton imposture would have been exposed to the full satisfaction of the jury in a single sitting by requiring Orton to make his own mark for comparison.

The difference between the general character of the rugæ of Hindoos and of Europeans is as apparent as that between male and female signatures, but my inspection of several thousands has not led me to think that it will ever be practically safe to say of any single person's signature that it is a woman's, or a Hindoo's, or not a male European's. The conclusions of your correspondent seem, however, to indicate greater possibilities of certainty. In single families I find myself the widest varieties

15, St. Giles, Oxford, November 13 W. J. HERSCHEL

P.S.—It would be particularly interesting to hear whether the Chinese have really used finger marks *in this way*. Finger-dips (mere blots) are common in the East, as "marks."

The Aurora of the 3rd Instant

MR. E DOWLEN has kindly communicated to me some particulars of the above as seen by him at Southport

He first noticed the aurora at 6h 50m (it had however been visible before that time) as a greenish white glow on the north horizon. This gradually rose until 7h. 45m., when the top of the arch was estimated at two-thirds of the way up between the horizon and the Great Bear It then gradually died out from the ends of the arch, and at 8h. 30m had disappeared. During the time it was watched the following changes took place —

From 7h. to 7h 15m it faded away from the eastern end until 7h. 30m , when nearly half the arch was gone The western end then seemed to gather itself up somewhat, and to get brighter. After this the ends again lengthened out until 7h. 45m , when the whole began to fade away. At 7h. 25m a narrow-arched band of black cloud concentric with the auroral arch was formed. It seemed to start from the ends, and meet over the middle point. At first this lay close upon the aurora. It then rose quickly, passed through the Great Bear, and vanished. It took about ten minutes to form, rise, and disappear.

Mr. Dowlen saw no streamers, but faint ones might have been present and escaped notice owing to adjacent gas-lamps. The aurora was at no time bright, and Mr. Dowlen doubts whether any beyond the green line would have been seen in the spectroscope.

The cloud formation detailed seems to me of considerable interest. J. RAND CAPRON

Guildown, November 19

Temperature of the Breath

THERE is no doubt that Dr Roberts has discovered the true explanation of the phenomena that puzzled me and a good many others to whom I showed them. I have repeated Dr. Roberts's method of heating the enveloping material so as to expel all moisture from it, cooling it down to the temperature of the room and then breathing through it. In every case where I did so the thermometer showed a rise to 112° and upwards at the end of a minute; at the end of two minutes the index was pushed into the small bulb at the top, showing a temperature of about 116°. It is evident, therefore, that the high temperature observed is not the actual temperature of the breath, but is

caused by the caloric evolved by the transition of the aqueous vapour of the breath into the liquid or solid form.

Before seeing Dr. Roberts's explanation I referred the matter to the greatest living authority on heat, and he, after carefully repeating my experiments, was of opinion that the heat was produced by the compression of the air when forced through the material. Had he known of Dr. Roberts's simple but ingenious variation of the experiment there is no doubt he would have accepted Dr. Roberts's explanation. R. E. DUDGEON

November 18

THE following experiment may serve to supplement the observations of Dr. Roberts as to the cause of the high reading of a thermometer wrapped in a handkerchief and placed in the mouth. An ordinary non-registering thermometer was wrapped in about twelve folds of a dry linen handkerchief placed in the mouth, and the following readings taken at intervals of one minute — Inspiration was effected through the nostrils, expiration through the handkerchief The thermometer was in the mouth from the beginning to the end of the experiment. Temperature under the tongue before commencing, 37°·0 C. The reading of the thermometer wrapped as above described, one minute after introduction into the mouth, was 43°·0. At the end of the second minute, 44°·1, 3rd 42°·9, 4th 41°·2, 5th 39°·6, 6th 38°·2, 7th 37°·1, 8th 36°·9, 9th 36°·9, &c. After the experiment the temperature under the tongue was 37°·6. Capillarity is probably the chief cause of the rapid condensation of water, and the consequent liberation of heat in the dry fabric.

In connection with the above I may mention a schoolboy's trick, viz, gripping the arm of a schoolfellow with the teeth and breathing forcibly through his coat-sleeve. The sensation of heat thus produced is much greater than when the breath is allowed to impinge on the bare skin.

In conclusion, I must freely confess that Dr. Dudgeon completely upset my objection, as to compression of the bulb having anything to do with the high reading, by the experiments quoted in his last letter. F J M P.

Coral Reefs and Islands

IN my letter on "Coral Reefs and Islands," published in NATURE, vol. xxii. p. 558, I have just noticed an important slip in writing which demands correction.

In the third paragraph and ninth line, for *metres* read *miles*, so that the passage shall read thus: "On the Florida coast we have barriers with channels 10–40 *miles* wide"

More accurately, the space between the southern coast of Florida and the line of Keys (old barrier reef) gradually widens from a few miles in its eastern to more than 40 miles in its western part. The channel between the line of Keys and the present reef is 6–7 miles wide and about 150 miles long.

Berkeley, California, November 2 JOSEPH LECONTE

Vox Angelica

I HAVE received a letter from Mr. Samuel Ray of Stoke Newington with reference to my remarks on the Vox Angelica stop on an Estey American organ. Mr. Ray informs me that Gordon's supplementary tuning-valve is used for the desired effects. The *rationale* of the method is, that by partly closing the mute the reeds are flattened, just as one reed is when the key is partially depressed. Mr. Ray also says, that by pulling out the stop a little way and making the reeds beat the latter are liable to be drawn out of tune; but this was the original method, but is now improved upon. A separate mute is placed on the top of the tubes, so that the wind strikes one of the sets of reeds vertically, whereby undue strain is avoided.

Woodville House, Rugby, November 18

Fascination (?)

PROBABLY none of your readers have thought it worth while to make any comment on the letters on this subject which have recently appeared, because it would seem needless to discuss the *origin* of "fascination" by means of the eye of a snake (or whatever may be the stimulus to the alleged condition) while all the evidence we can obtain from these reptiles in confinement proves that the condition does not exist. It devolves upon those who might object to observations on reptiles in a glass case as untrustworthy, to show us why—all their other actions being normal—the prisoners should not exhibit the same habit in respect to this "fascination," as they are alleged to practise when free. It is rather late in the year now; but if Mr. L. P Gratacap will take the first opportunity of seeing snakes feed, and if any of your readers will pay a visit to the Zoological Gardens, both he and they will, I think, come to the conclusion that, beyond the expression of a little surprise (on the part of ducks and pigeons chiefly) which soon wears off at the sight of an *unfamiliar* object, both the birds and animals regard the snakes with marked unconcern. I have seen a guinea-pig, after finding no place of exit from the cage, quietly settle itself down in the midst of the coils of an Australian constrictor, shut its eyes and go to sleep Ten minutes afterwards the snake had moved, and the guinea-pig was washing its face with its paws. Not once, but a dozen times, a rabbit has nibbled the nose of a River Jack viper (*V. rhinoceros*) in a pretty, inquiring way, heedless of the strong blows the reptile would administer with its snout to the impertinent investigator of that queer-looking object. For fully ten minutes one day a rabbit sat gazing at the poised and threatening head of a puff adder, now and then reaching forward to smell the reptile's nose, and anon sitting on its hind legs to wash its ears, and again returning to the "fascinating" object of its inquiries If during that time the rabbit had fallen into the state of trance, it was so soon released from that condition as to be able to attend to its own comfort and busy itself about its toilet The birds show no more recognition than the other animals of the dangerous position in which they are placed We see them hopping about on the snakes and pecking lustily at their scales, sitting on the branches, preening their feathers and behaving themselves just as though no such dreadful (or pleasing?) sensation as "fascination" was possible!

I saw once a sparrow perched upon the body of a snake twisted round a branch, and preening itself. By-and-by a constrictor crept up slowly, touched the bird with its nose, and then threw the crushing folds around it. The deliberate approach of the snake and the unconscious attitude of the sparrow, concerned about its private affairs, would have staggered any ordinary believer in "fascination." I have closely watched the behaviour of snakes *intent* on feeding. It may be a sudden rush, when the victim has no time to see its enemy, or the gradual, lazy advance of the reptile, in either case the doomed victim betrays no suspicion of danger—at least so far as I have been able to ascertain after passing some hundreds of hours contemplating the snakes in the unequalled representative collection of the Zoological Society.

The expression in Mr Gratacap's letter, "glittering" eyes, applied to the orbits of a snake, which are veiled by the "antocular" membrane, and capable of very slight movement, may remind us of Virgil's "Suffecti sanguine et igni," and help to confirm the "basilisk" (not a snake, by-the-by) superstition, but can only serve to perpetuate a myth. Whatever may be the value of Mr. Foot's opinion, I would ask, "Who has ever seen a snake 'raise its tail' after the manner of the cats?"

Charles Darwin has much to say on this subject to any one who chooses to consult the "Origin of Species." He does not see any advantage in the cat's "waving" tail or the noise of the "rattle" of *Crotalus*, for no predatory animal would derive any benefit from a signal of warning to its prey. The snake certainly never "waves" its tail when intent on mischief.

ARTHUR NICOLS

Soaring of Birds

REFERRING to NATURE, vol. xxiii. p. 10, may I suggest the following?—The question seems to be: "How can birds, having attained a certain elevation, thence rise without further muscular effort?" If I am not in error in what follows, they can theoretically do so if they *start* with a difference between their horizontal velocity and that of the wind, and *end* with a less difference; *e.g.*, if they start at rest with respect to the earth, and end by drifting with the wind entirely.

Take this last case, and consider the earth as plane, and the wind as horizontal, and having a velocity $= v$ with respect to the [earth and] bird. Finally we suppose the bird gains a horizontal momentum $= mv$. Then, by conservation of horizontal momentum, the only force acting being vertical, the air must lose an equal horizontal momentum.

Now we know that in all cases of bodies colliding and ultimately acquiring the same velocity, while we have conservation

of momentum we have loss of visible kinetic energy, except when the coefficient of restitution = 1. This kinetic energy is transformed into the vibrational kinetic energy of sound and heat in general.

But cannot we have it partly transformed into potential energy by "soaring" against gravity? On this supposition we have the two laws, conservation of momentum where no forces act, and conservation of energy, holding But we have visible kinetic energy lost and *partly transformed into potential energy with respect to the earth*, partly (as usual) into vibrational kinetic energy of sound and heat. [The *sound* is evident in the "singing" of the wings]

It seems to me that the swooping referred to by your correspondent is only a matter of convenience to the bird, and does not really affect the mechanical question, and that the comparison to a kite (which is held by a string) is not very satisfactory. But from my own observation of sea-gulls I do not think one can say that all the manœuvres and turns of the bird in the air are performed without real muscular effort, though certainly without *flaps* of the wing, and if there be muscular effort there can be work done—against gravity in this case

The above is only a suggestion I wish to induce some more mathematical reader to write a clear answer on this interesting question W. LARDEN

Cheltenham, November 8

The Photophone

ON reading the description published in NATURE, vol. xxiii. p 15, of Prof Graham Bell's wonderful discovery, the transmission of speech by light, I notice that in "the photophone" the varying of the intensity of the beam of light thrown on the receiving instrument is accomplished by the simple and ingenious means of allowing the sound waves to beat on the back of a thin plane mirror It seems to me, however, that this arrangement is not complete, and is open to some objection As the plane mirror will, if provision be not made against it, become convex and concave alternately, it must, unless the vibrations be confined within very narrow limits, give in one vibration *two* periods of maximum and minimum illumination at the receiver, and therefore the received sounds, apparently, should be (assuming the periods between each maximum and minimum illumination to be of the same duration, which could never exactly occur) an octave higher than those transmitted This I think follows from the fact that the rays from the mirror would be dispersed not only when convex, but also when concave, *after* they had passed the focus If, therefore, the vibrations of the mirror are sufficiently great to bring its focus between the mirror and the receiving instrument, there would be a second point of minimum illumination. If however the mirror were made slightly convex, or were constrained by a spring or otherwise, this defect would be cured

Curiously enough, *theoretically* "the photophone" is the more effective the greater the distance between the transmitter and the receiver, as the degree of variation of the intensity of light falling on the selenium will be, when perfectly adjusted, greater as the distance increases, and it is on this element that the intensity of the sound depends A. R. MOLISON

Ffynone Club, Swansea, November 15

[Our correspondent is obviously right in supposing that with a beam of light focussed accurately upon the selenium receiver a *single* complete vibration of the transmitting disk would produce *two* periods of maximum and minimum illumination This would not however be the case if the lenses were not set originally to exact focus, for then a displacement of the disk in one direction would scatter the rays more, while a displacement in the other would concentrate them more. In practice, we believe, exact focussing is never obtained or even attempted —ED]

Salts of Zinc

IN Roscoe and Schorlemmer, vol. ii p. 264, it states: "The salts of zinc do *not* impart to the non-luminous flame any tint," and on p. 258, "the metal burns with a bright *white* flame."

What then is the green colour imparted to the Bunsen flame by zinc sulphate due to? Also the green flame obtained by heating metallic zinc on charcoal before the blowpipe? S.

THE green tint referred to by "S." (*supra*) as imparted by zinc sulphate to the Bunsen flame is only observed whilst the water of crystallisation contained in the salt is being given off; the dry salt which remains imparts no colour to the flame It therefore appears probable that the green colouration of the flame is caused by very finely divided particles of the salt being carried off into the upper part of the flame by the escaping water of crystallisation These particles then become so intensely heated as to emit the peculiar greenish light and very likely suffer previous reduction by the carbon of the flame. Other zinc salts, especially the acetate, impart to the flame, when first heated, a greenish-blue tint resembling that observed when metallic zinc is burnt in the air, this being doubtlessly due to a partial reduction of the acetate. The characteristic zinc lines (6362 and 6099 in the red, and 4928, 4924, and 4911 in the blue) are not seen in the case of the salts or when the metal is burnt. A more correct description of the combustion of zinc than that referred to would be "the metal burns with a bluish-white flame."

Chemical Laboratory, Owens College W BOTT

THE WORKS OF CARL VON NÄGELI

THE beginning of the forties in the present century marks an important epoch in the history of botany The "Naturphilosophie" which had for many years so banefully influenced the development of the science, was being routed by the energetic attacks of Schleiden. Botanists were becoming alive to the fact that if their study was to have a place as a science by the side of physics and of chemistry, it must be pursued by the inductive method, that speculation must give way to research, and, above all, that development must be studied before any conclusions could be drawn from the investigation of mature forms. The early discoveries of von Mohl, and the demonstration of the cellular structure of the tissues by Schleiden, were among the first fruits of this awakening. To this period belongs also Nageli's first contribution to science—a paper on the Development of the Pollen (1842) The first sentence in the introduction shows how thoroughly Nageli was imbued with the same spirit which possessed Schleiden He says —"The right knowledge of an object includes an acquaintance with its mature form and a study of its development the one is dependent upon the other, and the one without the other is insufficient to afford a complete conception of the object." The actual observations detailed in the paper appear from the drawings to have been accurate, and they were an important addition to the knowledge of the subject; but their interpretation was so far influenced by Schleiden's theory of cell-formation, which was then prevalent, that the process of the development of the pollen grains is described as being one of free cell-formation.

In the year 1844 appeared the first number of the *Zeitschrift fur wissenschaftliche Botanik*, edited—probably on account of the sympathy existing between them—by Schleiden and Nageli. This short-lived periodical (1844 to 1846) was practically an organ for the publication of Nageli's researches and for the expression of his views, for it does not contain a single contribution from Schleiden's pen The first number opens with an article —a sort of confession of scientific faith—"On the Present Aims of Natural History, and especially of Botany," in which he gives an account of the actual state of botanical knowledge, and strongly urges the necessity of empirical study in order that the generalisations of the science might be in the future, not baseless speculations, but inductions resting upon a firm foundation of ascertained fact The *Zeitschrift* further contains an important paper "On the Nuclei of Cells and the Formation and Growth of Cells," in which the process of free cell-formation, which Schleiden had asserted to be universal, is shown to be only one of the processes by which a multiplication of cells is effected; these processes are clearly defined and classified. This is followed by a number of researches on the morphology of the lower cryptogams, which are of interest inasmuch as they open up new lines of approach to the study of the complicated morphology of more highly

organised plants. Nageli showed, for instance, that since in a unicellular alga (*Caulerpa*) a morphological differentiation of root, stem, and leaf is indicated, morphological is not dependent upon histological differentiation. He discovered also that in the organs of certain cryptogams growth is effected by the repeated segmentation of a single apical cell, and that this segmentation may take place always in one plane only (*Delesseria*), or in two or three planes (stem of *Echinomitrium*, *Phascum*, *Jungermannia*, leaves of mosses).

In the following year (1847) he published his work on "The Classification of the Algæ" ("Die Neueren Algensysteme"), which is of great value, partly on account of the acute criticisms on the various proposed classifications of this group of plants which it contains, but more particularly on account of the number of new facts concerning their structure and life-history which are contributed The descriptions of *Valonia*, *Udotea*, and *Acetabularia* may be especially mentioned it is shown that they have essentially the same structure as *Caulerpa*. The same praise may be awarded to another work, "The Genera of Unicellular Algæ," which appeared two years later.

The next publication of importance was the first number of the *Pflanzenphysiologische Untersuchungen*, and the most interesting of the papers which it contains is the one on the Primordial Utricle Attention is directed to its presence in all living cells, to its influence upon the osmosis of substances in solution into or out of the cell, and to its activity in forming the cell-wall, in short, it is clearly shown to be the living portion of the cell The second number did not appear until 1858, although the MS was ready in 1855, the delay being due principally to Nageli's removal from Freiburg to Zurich, and then again from Zurich to Munich on his acceptance of the Professorship of Botany in that University. Although it must have been vexatious, still the delay enabled Nageli to extend his researches in various directions and thus contributed materially to make the great work on starch-granules one of the most complete monographs which was ever written on any subject. This second number is entirely taken up by this work, which gives an account of these bodies, including their structure, development, chemical composition, and physical properties, as well as their distribution in plants It is a monument of patient, accurate investigation, devoted to a subject which appears, at first sight, to be of limited interest, but which ultimately suggested one of the most remarkable generalisations of modern times, namely, what is known as Nageli's theory of the structure of organised bodies. The primary fact upon which this theory is based is the property which starch-granules have of swelling-up—that is, of absorbing a certain amount of fluid with a consequent increase of bulk—when treated with certain reagents (dilute acids and alkalies), and of diminishing in size in consequence of a loss of water when treated with other reagents (alcohol). From these phenomena he inferred that the starch-granule consists of solid particles, which are impenetrable by water, but which are capable of taking up a certain amount of water between them, and that the amount of this water may vary according to circumstances When the granule is absolutely dry, these solid particles—to which he gave the name of *molecules*—apparently come into perfect contact, for the granule does not lose its transparency, which would be the case if air were included in its substance.

It may be remarked here parenthetically that the word *molecule* used by Nageli to designate these solid particles has not the same sense as it has when it is used in chemistry; one of these molecules is probably an aggregation of chemical molecules. In order to avoid any possible confusion on this score Nägeli has substituted the word *micella* for molecule in his more recent works. The forces by which these micellæ, with their surrounding watery areas, are held together are, firstly, the attraction existing between the micellæ, and secondly, the attraction which exists between each micella and the water which surrounds it; the latter of these attractions must necessarily be greater than the former, but whereas the former varies inversely as the square of the distance, the latter must vary inversely as some higher power Thus, if A represent the attraction between two micellæ, B the attraction between a micella and the water, and D the distance between two micellæ, the limit of swelling-up or imbibition will be reached when $\frac{B}{D^{2+x}} = \frac{A}{D^2}$. As to the form of the micellæ, it is evident that they are not spherical or oval, for in that case the starch-granules would necessarily contain air when dry, and further, the denser parts of them would have to contain at least 26 per cent of water, whereas, as a matter of fact, they only contain 14 per cent They must be therefore more or less polyhedral, but they are not equiaxial since the swelling-up does not take place equally in all directions

By this theory it was found possible to explain satisfactorily certain difficult points of structure, such, for instance, as the stratification of starch-granules and the striation and stratification of cell-walls All these depend upon the alternation, in one or more planes, of dense and less dense layers. The proportion of solid to fluid is greater in the dense than in the less dense layers, or, in the terms of Nageli's theory, the relative size of the micellæ to the watery areas surrounding them is greater in the layers of greater density Further, this theory affords a satisfactory explanation of the mode of growth of a cell-wall It is easy to understand that when the limit of extensibility is nearly reached—that is, when the micellæ of the membrane are separated as far as possible—new micellæ can be deposited in the interstices, the extended condition of the membrane being thus rendered permanent This mode of growth is commonly known as *growth by intussusception*.

This is the stage to which the development of the theory is brought in this work. In the year 1862 Nageli published a paper in the *Proceedings* of the Bavarian Academy on the "Application of Polarised Light to the Study of the Structure of Plants," which advanced it very considerably. He found, in the first place, that organised structures, such as starch-granules or cell-walls, are doubly refractive, and that this property is not affected by causing them to increase or diminish in size in consequence either of the absorption or removal of water, or by mechanical stretching or pressure. From this he concluded that the double refraction is not a property of the organised structure as a whole, but that it belongs to each individual micella hence these micellæ must be crystalline. Again, from the interference colours which these objects present when examined with polarised light, he ascertained that the crystalline micellæ have three axes of elasticity, that they must be bi-axial crystals; and further, by comparing the effect produced by the passage of polarised light through glass under various degrees of pressure, he arrived at the conclusion that the micellæ are so arranged in the membrane of which they form part that one of their axes of elasticity is perpendicular to the surface, whereas the other two axes lie in the plane of the membrane. In a subsequent paper contained in the same periodical, he shows that the crystals of proteid substance, which occur in various seeds and tubers, have the same molecular constitution as starch-granules and cell-walls By close and acute reasoning from carefully observed facts, Nageli has therefore succeeded in establishing this theory of the molecular constitution of organised bodies, a theory which satisfactorily explains many of the peculiarities of structure and properties which they present There can be little doubt that it is justifiable to extend this theory to the explanation of the intimate structure of protoplasm, in fact, in his later publications Nageli has asserted as much, and in

this he is supported by such authorities as Sachs and Strasburger; but it is impossible to say anything at present as to the form and arrangement of the micellæ of protoplasm beyond this, that they do not so act upon polarised light as to suggest that they are crystalline Full details on this subject, as well as a vast amount of other information, is given in the treatise on the Microscope (second edition, 1877), which Nageli wrote together with Schwendener; fortunately an English edition of this important work may soon be expected to appear.

In tracing the development of Nageli's theory, it has been necessary to depart from the chronological order of his works In the years between 1858 and 1868 he published his *Beiträge zur wissenschaftlichen Botanik*, which include several important works, for the most part anatomical. In the first number there is an elaborate paper on "The Arrangement of the Fibro-vascular Bundles and the Mode of Growth in the Stem and Root of Vascular Plants," which is important as containing a purely morphological classification of the different forms of tissue of which these organs consist. This is followed by a detailed account, in the fourth number, of the mode of growth in thickness and of the arrangement of the fibro-vascular bundles in the stem among the Sapindaceæ, and this number also contains Nageli's well-known investigation into the mode of development and growth of roots, in which Leitgeb was associated with him This publication has a further interest connected with it, in that Schwendener's first papers on what is now known as his Lichen-theory appeared in it.

During this period Nageli frequently contributed papers (the *Botanische Mittheilungen*) on a variety of subjects of botanical interest to the *Proceedings* of the Bavarian Academy, an activity which continues up to the present time. Allusion has already been made to some of these, and it would be worth while, did space permit, to give an account of most of them Among the more important the following may be mentioned —"On the Sieve-Tubes of Cucurbita," "On the Proteid Crystalloids of the Brazil-nut," "On the Development of Varieties," "A Theory of Hybridisation." Of late years Nageli has turned his attention more especially to the study of the chemical composition and vital processes of the lower Fungi, such as Yeast and Bacteria Among the interesting results obtained is the discovery, in yeast-cells, of a ferment (invertin) which converts cane- into grape-sugar, and of peptones But the real importance of these researches only became apparent on the publication of two larger works, viz. "The Lower Fungi in their Relation to Infectious Disease" (1877), and "A Theory of Fermentation" (1879) It is of course impossible to give here anything like a satisfactory account of the contents of these two books. The first treats fully of the important part played by Bacteria in infection and contagion, showing, in fact, that these organisms are the causes and carriers of the various forms of disease. In the second, after an exhaustive account of the process of alcoholic fermentation has been given, a new theory of it is propounded, based, not upon chemical principles, like that of Liebig, but upon the principles of molecular physics. Fermentation is defined as being "the communication of the oscillations of the molecules, groups of atoms, and atoms of the substances composing the living protoplasm to the molecules of the fermentible substance, in consequence of which the equilibrium of the molecules of that substance is disturbed, and decomposition is the result." It is also pointed out that, in the case of yeast, the sugar is to some extent decomposed within the cells, but for the most part outside them.

Though this account of his works is but little more than an enumeration of them, yet it will suffice to show how important are Nageli's contributions to botanical science in the departments of morphology, anatomy, and physiology, not merely as additions to the accumulated store of facts, but as new generalisations from those facts, and as opening up fields for future research.

SYDNEY H. VINES

PROF. TAIT ON THE FORMULA OF EVOLUTION[1]

ANOTHER point to which I ought thus early to direct your attention is the necessity for perfect definiteness of language in all truly scientific work. Want of definiteness may arise from habitual laziness, but it much more commonly indicates a desire to appear to know where knowledge is not. Avoid absolutely all so-called scientific writings in which (as Clerk-Maxwell said) the attempt is made to "give largeness of meaning" to a word by using it sometimes in one sense and sometimes in another. It is true that we may thus economise in our language, and avoid the necessity for introducing new and hard terms But it would be a most expensive and pernicious economy. It is only a blockhead who could object to the use of a new term for a new idea.

Our only source of information in physical science is the evidence of our senses. To interpret truly this evidence, which is always imperfect and often wholly misleading, is one of the tasks set before Reason It is only by the aid of reason that we can distinguish between what is physically objective, and what is merely subjective Outside us there is no such thing as noise or brightness:—these no more exist in the aerial and ethereal motions, which are their objective cause, than does pain in the projectile which experience has taught us to avoid You will find many prominent ideas, relics of a less enlightened age, from which Natural Philosophy has not yet wholly shaken itself free, which owed their existence solely to the confusion of the subjective with the objective

With observation and experiment as our sole sources of information we have no right, in physical science, to introduce *à priori* reasoning We may (unprofitably of course) speculate on what things might have been, but we must not dogmatise on what they ought to have been, we must simply try to discover what they are.

For aught that we can tell, the properties of matter, and physical laws in general, might have been other than we find them to be How can any one of us tell whether his conscious self might not have been associated in life with the body of an Eskimo or of a New Zealander, instead of with what he (no doubt) considers its much preferable tenement? Speculations of such a kind must always be wholly unproductive and unprofitable, but for all that we cannot but allow that they are not intrinsically absurd

Some years ago a critic of Mr. Herbert Spencer's Philosophy happened to quote from a book of mine the remark I have just made (that the properties of matter might have been other than we find them to be). Mr. Spencer's observation on this point is highly instructive Had he not been a severely grave philosopher I should have taken it for a joke. He said, "Does this express an experimentally ascertained truth? If so, I invite Prof. Tait to describe the experiments."[2] Mr Spencer has quite recently published a species of analytical inquiry[3] into my "mental peculiarities," "idiosyncrasies of thought," "habits of mind," "mental traits," and what not. From his illustrative quotations it appears that some or all of these are manifested wherever there are differences between myself and my critic in the points of view from which we regard the elements of science. Hence they are not properly personal questions at all, but

[1] Part of an Introductory Lecture delivered October 26, 1880

[2] In my letter (NATURE, vol ix p 402) will be found an illustrative anecdote, which Mr. Spencer declares to be "*not to the point*" A great scientific man, to whom I showed the correspondence, remarked that Mr Spencer must be the only man in England who could not see the perfect appositeness of the anecdote.

[3] *Appendix to First Principles, dealing with Criticisms.* (Williams and Norgate, 1880)

questions specially fitted for discussion here and now. I may, therefore, commence by inquiring what species of "mental peculiarity" my critic himself exhibited when he seriously asked me whether I had proved *by experiment* that a thing might have been what it is not!!

The title of Mr. Spencer's pamphlet informs us that it deals with *Criticisms*; and I am the first of the subjects brought up in it for vivisection, albeit I have been guilty (on Mr. Spencer's own showing) only of "*tacitly*" expressing an opinion! Surely my vivisector exhibits here also some kind of "mental peculiarity." Does a man become a critic because he quotes, with commendation if you like, a clever piece of analysis or exposition published by another?

In NATURE for July 17, 1879, I reviewed Sir E. Beckett's able little book, "Origin of the Laws of Nature," and as an illustration of that author's method I said:—

"He follows out in fact, in his own way, the hint given by a great mathematician (Kirkman) who made the following exquisite translation of a well-known definition:—

"'Evolution is a change from an indefinite, incoherent, homogeneity to a definite, coherent, heterogeneity, through continuous differentiations and integrations.'

"[Translation into plain English]—'Evolution is a change from a nohowish, untalkaboutable, all-alikeness, to a somehowish and in-general-talkaboutable not-all-alikeness, by continuous somethingelsifications and sticktogetherations.'"

Later in my article occurs the following paragraph, which also is quoted by Mr. Spencer:—

"When the purposely vague statements of the materialists and agnostics are thus stripped of the tinsel of high-flown and unintelligible language, the eyes of the thoughtless who have accepted them on authority (!) are at last opened, and they are ready to exclaim with Titania

"Methinks 'I was enamour'd of an ass.'"

The translation is from Kirkman's remarkable work, "Philosophy without Assumptions," which at that date I had just read with pleasure and profit. Humiliating as the confession may appear, I there saw Mr. Spencer's "Formula" for the first time, and I did not notice the title given to it. Hence, in quoting it from Kirkman, I very naturally called it by its proper name, a "Definition." For this I have incurred the sore displeasure and grave censure of the inventor of the definition. It seems I should have called him the *discoverer of the formula*! Now this is no petty quibble on words. It involves, as you will see immediately, an excessively important scientific distinction, to which your attention cannot be too early directed.

Mr. Spencer complains that an American critic (whose estimate is "tacitly" agreed in by Mr. Matthew Arnold) says of the "Formula of Evolution":—"This may be all true, but it seems at best rather the blank form for a universe than anything corresponding to the actual world about us." On which I remark, with Mr. Kirkman, "Most just, and most merciful!" But mark what Mr. Spencer says:—

"On which the comment may be that one who had studied celestial mechanics as much as the reviewer has studied the general course of transformations, might similarly have remarked that the formula—'bodies attract one another directly as their masses and inversely as the squares of their distances,' was at best but a blank form for solar systems and sidereal clusters."

We now see why Mr. Spencer calls his form of words a *Formula*, and why he is indignant at its being called a *Definition*. He puts his Formula of Evolution along-side of the Law of Gravitation! Yet I think you will very easily see that it is a definition, and nothing more. By the help of the Law of Gravitation (not very accurately quoted by Mr. Spencer) astronomers are enabled to predict the positions of known celestial bodies four years beforehand, in the *Nautical Almanac*, with an amount of exactness practically depending merely upon the accuracy of the observations which are constantly being made:—and, with the same limitation, the prediction could be made for 1900 A.D., or 2000 A.D., if necessary. If now Mr. Spencer's form of words be a formula, in the sense in which he uses the term as applied to the Law of Gravitation, it ought to enable us to predict, say four years before-hand, the history of Europe, with at least its main political and social changes! For Mr. Spencer says that his "formula" expresses "all orders of changes in their general course,—astronomic, geologic, biologic, psychologic, sociologic", and therefore "could not possibly be framed in any other than words of the highest abstractness."

Added, November 11, 1880

Mr. Kirkman has lately "discovered a formula" more general than that of Evolution, the "Formula of Universal Change." Here it is:—

"Change is a perichoretical synechy of pamparallagmatic and porroteroporeumatical differentiations and integrations."

Even to this all-embracing formula, with Mr. Spencer's leave, I would apply the humbler but fitter term "definition."

Of Mr. Spencer's farther remarks there are but three which are directed specially against myself (Mr. Kirkman is quite able to fight his own battles). He finds evidence of "idiosyncrasies" and what not, in the fact that, after proclaiming that nothing could be known about the physical world except by observation and experiment, I yet took part in writing the "Unseen Universe"; in which arguments as to the Unseen are based upon supposed analogies with the seen. He says:—"clearly, the relation between the seen and the unseen universes cannot be the subject of any observation or experiment, since, by the definition of it, one term of the relation is absent." I do not know exactly what "mental peculiarity" Mr. Spencer exhibits in this statement. But it is a curious one. Am not I, the thinker, a part of the Unseen, no object of sense to myself or to others, and is not that term of relationship between the seen and the Unseen always present? But besides this, Mr. Spencer mistakes the object of the book in question. The theory there developed was not put forward as probable, its purpose was attained when it was shown to be conceivable and not inconsistent with any part of our present knowledge.

Mr. Spencer's second fault-finding is *àpropos* of a Review of *Thomson and Tait's Nat. Phil.* (NATURE, July 3, 1879) by Clerk-Maxwell, knowing of course perfectly well that the authors were literally quoting Newton, and that they had expressly said so, jocularly remarked "Is it a fact that 'matter' has any power, either innate or acquired, of resisting external influences?" Mr. Spencer says:—"And to Prof. Clerk-Maxwell's question thus put, the answer of one not having a like mental peculiarity with Prof. Tait, must surely be—No." Mr. Spencer, not being aware that the passage is Newton's, and not recognising Maxwell's joke, thinks that Maxwell is at variance with the authors of the book!

Finally, Mr. Spencer attacks me for inconsistency &c. in my lecture on Force (NATURE, September 21, 1876). I do not know how often I may have to answer the perfectly groundless charge of having, in that Lecture, given two incompatible definitions of the same term. At any rate, as the subject is much more important than my estimates of Mr. Spencer's accuracy or than his estimates of my "mental peculiarities," I may try to give him clear ideas about it, and to show him that there is no inconsistency on the side of the mathematicians, however the idea of force may have been muddled by the metaphysicians. For that purpose I shall avoid all reference to "differentiations" and "integrations"; either as they

are known to the mathematicians, or as they occur in Mr. Spencer's "Formula." Of course a single line would suffice, if the differential calculus were employed.

Take the very simplest case, a stone of mass M, and weight W, let fall. After it has fallen through a height h, and has thus acquired a velocity v, the Conservation of Energy gives the relation

$$M\frac{v^2}{2} = Wh$$

Here both sides express *real things*, $M\frac{v^2}{2}$ is the kinetic energy acquired, Wh the work expended in producing it.

But if we choose to divide both sides of the equation by $\frac{v}{2}$ (the average velocity during the fall) we have (by a perfectly legitimate operation)

$$Mv = Wt,$$

where t is the time of falling. This is read—*the momentum acquired is the product of the force into the time during which it has acted* Here, although the equation is strictly correct, it is an equation between purely artificial or non-physical quantities, each as unreal as is the product of a quart into an acre. It is often mathematically convenient, but that is all The introduction of these artificial quantities is, at least largely, due to the strong (but wholly misleading) testimony of the "muscular" sense.

Each of these modes of expressing the same truth, of course gives its own mode of measuring (and therefore of defining) force

The second form of the equation gives

$$W = \frac{Mv}{t}$$

Here, therefore, force appears as the time-rate at which momentum changes, or, if we please, as the time-rate at which momentum is produced by the force In using this latter phrase we adopt the convenient, and perfectly unmisleading, anthropomorphism of the mathematicians This is the gist of a part of Newton's second Law.

The first form of the equation gives

$$W = \frac{M\frac{v^2}{2}}{h},$$

so that the same force now appears as the space-rate at which kinetic energy changes, or, if we please, as the space-rate at which energy is produced by the force

Here are some of Mr Spencer's comments—"force is that which changes the state of a body, force is a rate, and a rate is a relation (as between time and distance, interest and capital); therefore a relation changes the state of a body."

The contradiction which Mr. Spencer detects here, and over which he waxes eloquent and defiant, exists in his own mind only. The anthropomorphism which has misled him is but a convenient and harmless relic of the old erroneous interpretations of the impressions of sense.

P. G. TAIT

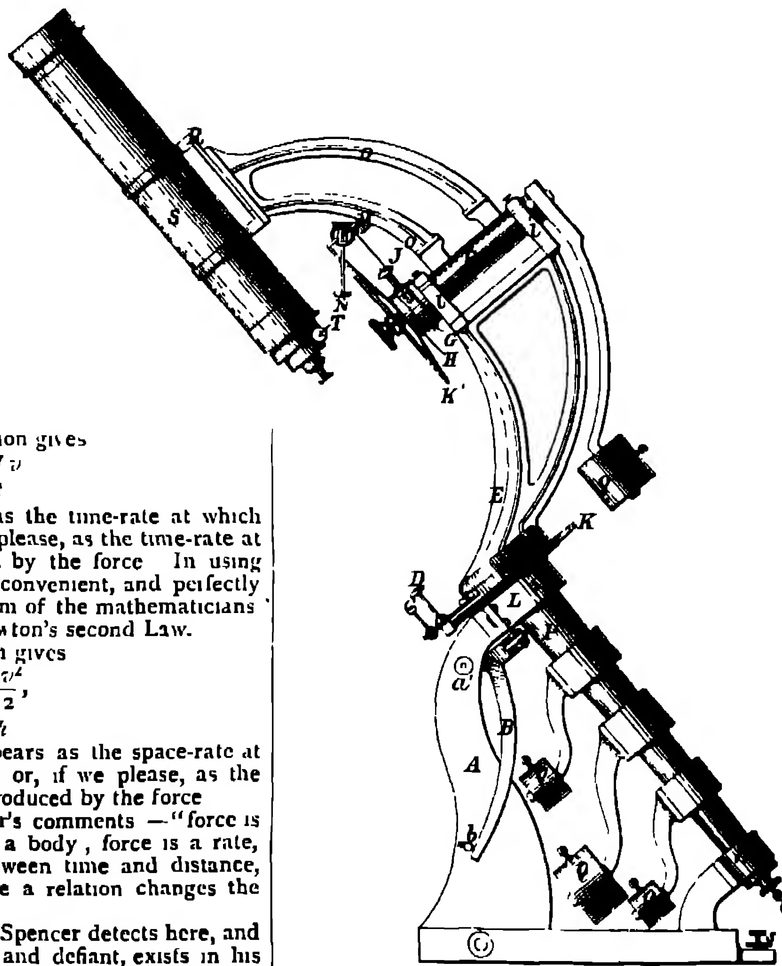
COMET-FINDERS

IT is only lately that the meteorites, or many of them which we see of a night making bright streaks in the heavens, have been shown to belong to definite streams having definite orbits and periods, and with the increase of our knowledge of these orbits the number of comets identified as travelling in the same orbits as meteor-streams has likewise advanced.

Now that the intimate relation between comets and meteorites has been settled, greater interest attaches to the discovery of these casual visitors, many of which have passed in our neighbourhood unobserved This is shown by the increased number of comets seen, now that it is part of the business of several observatories to keep up a systematic search

To do this properly, a telescope of large field of view is required, and a constant sweeping of the heavens must be kept up, and to do this with an ordinary equatorial is extremely tedious, owing to the continual change of the position of the body required.

To go back to early days of comet-finding, we call to mind the first instrument specially constructed for the purpose, so far as we are aware It is a telescope of Galilean construction, with an object-glass of 2½ inches



diameter, and having a total length of 5 inches. This was made by Dollond during the first few years of this century for Dr. Kitchener Since that time astronomical instruments have grown apace, and we have now before us Dr. Carl's "Repertorium fur Experimental-Physik" containing a description of the new comet-finder constructed by Herr Schneider for the Observatory at Vienna.

The telescope of this instrument has an object-glass of

6 inches aperture and 4½ feet focal length, and the mounting is a striking change from what we are usually accustomed to see. The great point to be attained by it is to carry the telescope equatorially and allow it to move on a declination axis in such a manner that the eye-end remains stationary while sweeping the heavens It will be seen from the plate which, by the kindness of Dr. Carl, we are able to reproduce, that the declination axis is carried above the polar axis somewhat in the usual way, but that the telescope, instead of being carried by its middle at the end of the declination axis, is carried by a frame, O, so that the eyepiece is in the prolongation of that axis, and also in the prolongation of the polar axis, so that it remains stationary, while the object-glass sweeps in all directions. The handles D and N, within easy reach of the observer, enable him to give the requisite motion to the telescope without the change of position necessary with an ordinary instrument The telescope is balanced on the declination axis F by the counter-weight Q, and the excess of weight on one side of the polar axis is balanced by the counter-weights Q Q Q

Herr Schneider proposes to mount telescopes of much greater size, say 30 or 40 feet long, in the same manner.

NOTES

M. MILNE-EDWARDS having completed the publication of his great work on "Physiologie Comparée," a subscription has been opened by M Dumas, the Perpetual Secretary of the Academy of Sciences, for the purpose of presenting the veteran zoologist with a gold medal. Subscriptions are to be sent to M Maindron at the Secretariat of the Academy of Sciences, or to M. Victor Masson, publisher, Boulevard St Germain, Paris M. Milne-Edwards's great work is composed of fourteen large octavo volumes—the first four of which are out of print—of 500 pages each; the publication began in 1857, and has been accomplished by twenty-three years of continual work It includes all the lectures which have been delivered by M Milne Edwards at the Museum of Natural History during that lengthened period, and could not have been accomplished if the author had not had the advantage of the immense scientific resources accumulated in that establishment during the last two centuries for the study of nature.

A VIENNA correspondent sends us the following data regarding the Agram earthquake:—The damp ejected matter of the mud-volcano at Resnica near Agram was found to contain no elementary sulphur nor sulphuretted hydrogen, but it contained sulphur metals decomposable by acids, and earthy carbonates, along with organic substances of a humus nature The chief constituent of it is fine sand with water, and it comes from no great depth. The mud volcano at Sevete, near Agram, also ejects (2 m. high) chiefly a clayey-sandy mud, which may be thrown up by movements of the ground water The Gratz geologist, Peters (writing in the *Tagespost*), characterises the Agram earthquake of November 9 to 14 as one of the most normal which could be observed in that region. The movement kept exactly the direction of south-south-west, and was thus precisely at right angles to the chief direction of the Eastern Alps The entire breadth of the territory affected appears to be indicated by the towns of Klagenfurt (Carinthia) and Szegedin (Hungary). Since the formation of the Alps, and so through a long series of geological periods, all subterranean movements in this region of Central Europe have been in this one direction (as Suss first showed). For some months past movements have been perceived to be in progress in various localities. That Agram should be affected as it has been is explained by an inspection of the geological map Not very far north from that town rises a remarkable block of greenstone surrounded by chlorite schist, limestone and other layers. A not very broad band of recent Tertiary deposits separates the low ground from that mountain block, which thus forms a comparatively fixed point in the system. Every movement coming from south south-west propagated by these strata must impinge horizontally on the green stone block, and cause a greater or less curvature of the strata, which manifests itself most where the lower ground remains free from Tertiary deposits. Unfortunately for Agram the strongest movement was directed precisely against that mountain block, and so upon the town before it The whole phenomenon has nothing to do with volcanic processes. The repetition of the shocks is easily explained by the reaction from curvature of the strata not occurring all at once. In opposition to Peters, the astronomer and meteorologist, Rudolph Falb of Gratz, holds the Agram earthquake to be volcanic, and connected with the strong attraction of subterranean lava by the moon They seem to have continued at more or less frequent intervals during the past week.

IN several parts of the Tyrol (Hall, Thaur, Rum, Innsbruck) an earthquake-shock was experienced on the 14th inst. about 9 15 a m, and on the same day there was a considerable shock (lasting 20 sec.) in Bavaria, at Partenkirchen and Mittenwald about 8 p.m. Dr. Franz Woehner has been delegated by the Vienna Academy to Croatia to report on the phenomena.

A CYCLONE accompanied by earthquake shocks is reported to have occurred at Sitka in Alaska on October 25, causing much devastation.

JUST after the death of its founder, Dr Broca, the well known *Revue d'Anthropologie* entered on its tenth year His successor in the direction of the *Revue*, Dr. Topinard, issues a prospectus intimating that it will be continued with renewed energy on the lines laid down by its founder. The *Revue* embraces all the varied departments of anthropology, and its editor has the collaboration of the most eminent workers in the varied departments in France Broca left a great number of anthropological papers in various stages of completeness, and these are to be published in successive numbers of the *Revue*, which deserves every encouragement.

THE laboratory of M Lacazes Duthiers at the Sorbonne has been opened this year again for experiments in zoology In the summer it will be transferred to the coast station in Brittany

THE Paris Museum of Natural History being situated in a somewhat out-of-way place, is rather deserted by the students, and great efforts are made to render the course of lectures which are delivered there unusually attractive. M. Fremy, Lecturer on Chemistry, will speak on the great discoveries in chemistry made almost simultaneously in Paris and in London about a century ago, and will perform all the original experiments, some of them with the very instruments which were used by the discoverers.

A VERY interesting acquisition has just been made by the botanical department of the British Museum In 1783–4 John Millar made a series of water colour drawings for the Earl of Bute, showing the "leaves, stalks, and ramifications of plants, for the purpose of ascertaining their several species" They are bound in five volumes, with an elaborately flourished title page, and fill 928 octavo pages. The museum has purchased the drawings.

THE seismograph on Mount Vesuvius is said to indicate great subterranean dynamism Streams of lava continue to flow down the north-west side of the cone, and are increasing both in volume and number. "The Vesuvian eruption," the *Times* correspondent states, "has entered on a phase of greatly increased activity. The news reached us on Saturday, but, as it appeared only in those papers which are directly interested in the Funicular

Railway, it was looked upon as an exaggeration to attract Sunday excursionists. It is now, however, confirmed that the lava is flowing over the side towards Naples, and, after having destroyed the outwork built to protect the upper station of the railway, is running rapidly in a vivid streak of fire parallel to the line, but at a distance which does not thus far imperil its safety. The spectacle is described as magnificent, and crowds were out watching the course of the lava and speculating on the fate of the Funicular Railway."

AN International Congress of Electricians accompanied by an International Exposition of Electricity will be held in Paris during the autumn of 1881. This Exposition is to be opened (under the patronage of the Government, though at the pecuniary risk of private parties) on August 1, and to continue until November 15 following. The Congress of Electricians will meet on November 15 in the rooms of the Palace of the Trocadéro. Opportunity will be given for exhaustive research in all the various branches. The Exposition will remain open each evening until eleven o'clock to afford opportunities of testing the practicability of the different systems of electric lighting. The Congress is to assemble under the presidency of the Minister of Posts and Telegraphs, and the vice presidency of three French and three foreign delegates.

ON February 10, 1879, a few gentlemen interested in the study of man met in the Smithsonian Institution to devise a method of mutual improvement The effort resulted in the formation of the Anthropological Society of Washington, with Major Powell for president, and Dr. Reynolds and Prof O T Mason as recording and corresponding secretaries. Twenty-four papers have been read, which, if one might judge from their titles, are most interesting and valuable contributions We learn from the *American Naturalist* that it is not yet decided whether a journal will be published, inasmuch as the Smithsonian Institution and the Bureau of Ethnology "afford ample opportunities of preserving all papers of permanent value." Without doubting this fact, we still hope that this young and vigorous society may not only have its own publication, but also that a long career of activity may ensue to provide the material for filling the pages of the same.

HERR V. BERGSO, in a recent work, "Fra Mark og Skov,' has given some interesting data in regard to the habits of the Tarentula, *Lycosa tarentula*, Latr, whose nests he has traced and examined on the Roman Campagna. He found that the nest, which was well rounded and smooth, was approached by a tunnel which, after running about a foot straight down below the surface of the ground, made a sudden short turn before it finally descended for about another foot into the spider's abode The entrance to the tunnel is concealed by an arched covering made by the interlacing of grasses and leaves. The eggs are inclosed in a spun bag, and the young appear in the autumn, when they immediately seat themselves on the body of the mother where they remain till about April, neither parent nor offspring seeking food during their hybernation. As many as 291 individuals were on one occasion removed in February from the body of an emaciated tarentula. The superstitious error of assuming that the bite of the animal induces an irresistible desire of dancing is due to the fact, that dancing having been originally employed as a remedy against the poison, which is believed to be eliminated by profuse perspiration, the action of the poison was confounded with the means of its eradication.

EXOTIC butterflies have long, from their beauty, engaged the enthusiastic attention of wealthy collectors, some of whom, as notably the late Mr. Hewiston, have also enriched entomological literature with works containing coloured figures of their favourite insects. M. C. Oberthür of Rennes, who, with his brother René, is the possessor of a very extensive entomological museum, in which is contained the late Dr. Boisduval's collection of Lepidoptera, has just published his Quatrième livraison of a work, "Études d'Entomologie," which has more or less regularly appeared during the last few years. The present part is devoted to the "Papilionidæ" of his collection, and six coloured plates illustrate the species and varieties which he considers it necessary to describe.

MUCH interest has been excited in Norway by the recent appearance of a colony of beavers on the Voldifjord, a branch of the Frierfjord, which is at a considerable distance from the beaver-station still remaining at Omli on Nedenæs.

UNDER the title *Iagttagelser over Nordlys anstillede i Norge, Sverige og Danmark*, bearbeidede af Sophus Tromholt (Christiania), we have the results yielded by 839 observations of the aurora borealis, at 132 Scandinavian stations, on 154 nights, between September 1878 and April 1879 on which the northern light was visible. These observations are arranged under four heads in accordance with (1) longitude and latitude of stations; (2) time of year and age of moon; (3) colour, form, and altitude of streamers; (4) sound. Herr Tromholt considers that it may be accepted as certain, that the aurora is a local phenomenon, circumscribed by narrow limits, and manifested at inconsiderable distances from the earth's surface; that the light is generally white, and less often red or green, but that in latitudes higher than Bergen it not unfrequently presents spectral colours; and that the accompaniment of sound is an indisputable fact in relation to the auroral phenomenon. We learn from *Naturen* that Herr Tromholt has resumed his observations of the aurora borealis, to which he has devoted his attention for many years. It is his intention to make a catalogue of every recorded manifestation of the northern light in Norway, and for this purpose he requests the co-operation of other observers, and will be grateful for reference to any foreign sources of information, such as ships' logs, journals, weather tables, almanacs, &c., which might yield materials towards the better elucidation of this phenomenon.

IN a letter addressed to Mr. Cust by Prof. F. W. Newman, and just published in the *Journal* of the Royal Asiatic Society, on the Libyan languages, the writer remarks that St Augustine in his own day attested that one language prevailed in Roman Africa, and that it was quite natural to suppose the same to be the case now, when a large and striking similarity was found in the leading nouns and verbs. The changes however induced in 1500 years have broken up the original unity, and Prof Newman states that we are now forced to admit at least four languages, each differing from the other more than German from Dutch, or Portuguese from Spanish.

THE annual course of five lectures in connection with the Brown Institution will be delivered by Dr. W. S. Greenfield, Professor-Superintendent, in the theatre of the University of London, Burlington Gardens, W., on December 13, 15, 17, 20, and 22, at 5 30 p m. Subject Further Investigations on Anthrax and Allied Diseases in Man and Animals. Microscopic specimens will be exhibited on December 22 from 4.30 p.m.

WE learn from *Psyche* that Miss Emily A. Smith, a well-known entomologist of Peoria, Illinois, has gone to Leipzig, where, if the university authorities will allow it, she will pursue a general course of zoological work in the new laboratory of Prof. Leuckart This lady was recently elected a member of the Entomological Society of London.

CAPT. H. KING, R.N., writes with reference to the instances of fascination mentioned at p. 56, vol. xxiii., that having heard that the American ostrich might be enticed within gunshot by a person lying upon his back and kicking his legs and arms in the

air, he tried this with perfect success in Uruguay; he supposes that curiosity was the motive. A large coral upon the copper of a man-of-war, Capt. King states, is not unprecedented, he remembers in 1839 seeing one of the size and shape of a large cauliflower, taken from the bottom of a vessel of the Indian navy, in the Persian Gulf, by a pearl-diver.

PROF. GRAHAM BELL has promised to read a paper before the Society of Arts upon his "Photophone" at the ordinary meeting on Wednesday, December 1. As considerable interest is likely to attach to this paper it is announced that only members of the Society can be admitted, and that they will be required to provide themselves with special tickets issued for the occasion.

WE referred in the "Physical Notes" of our issue of November 11 to a paper read before the American Association at Boston by Prof. Young, which combated certain phenomena in thermo electricity which were alleged to have been observed by Herr Exner. We have since received from Mr T. Brown of Belfast a letter in which, on behalf of Prof Franz Exner of Vienna, he expressly disavows any such discoveries as those which Prof Young has set himself to refute. We readily accord to our courteous correspondent the opportunity for this disavowal, since any reflections cast even inadvertently upon the accuracy of Prof. Franz Exner's work might unfairly prejudice readers against the general reliability of the researches which he has published in another department of science, and which our readers are aware are just now exciting considerable attention

IN NATURE, vol. xxii. p. 616, it was stated, on the authority of the Japanese papers, that Prof. Atkinson had, "during a sojourn in the Mitake Mountains of the Province of Koshu, discovered another valuable deposit of coal." We are now informed that although Mr. Atkinson visited the Mitake Mountains last summer, he can lay no claim to so important a discovery.

THE Hon Sir Ashley Eden, K C S.I., has appointed Babu Ambika Churn Sen, M.A., and Synd Sakhawat Hossein, B.A, a native of Behar, to the two scholarships of 200*l*. a year each, recently created by the Bengal Government to be held at the Royal Agricultural College, Cirencester.

THE Procureur-General of Paris having sent an explanatory note stating that he did not mean to attack the character of the medical advisers of the public prosecutor, but merely to give vent to his peculiar views, these gentlemen have withdrawn their resignations and resumed their work.

THE Cutlers' Company have arranged for a course of lectures being delivered, or papers read, at the hall of the company during the ensuing winter season. The course will consist of four lectures or papers upon subjects intimately connected with the materials used in the manufacture of cutlery, the lectures to take place on the following dates:—Wednesday, December 1, 1880, Wednesday, January 5, 1881; Wednesday, February 2, 1881; Wednesday, March 2, 1881. Sir Henry Bessemer, C.E, F.R.S., has promised to commence the course, and will, on December 1, read a paper "On the Manufacture and Uses of Steel, with special reference to its employment for Edge Tools." The admission will be entirely free, but by ticket, which may be obtained on application to the hon. secretary, addressed to the Cutlers' Hall.

IT is announced that the electric cable manufacturing firm, Berthoud Borel and Co. of Cortaillod, in Neuchâtel, have made a highly important discovery in practical telegraphy. After a long and expensive series of experiments they have succeeded in devising a method of laying cables whereby the inductions of the electric current from one wire to another, although the wires are in juxtaposition, is prevented. This discovery, it is asserted, removes the last obstacle in the way of the widest possible extension of facilities for telephonic communication.

OUR ASTRONOMICAL COLUMN

THE THIRD COMET OF 1869.—This comet, the orbit of which has so close a resemblance to that of the comet discovered by Mr. Swift on October 11, was detected at Marseilles by M. Tempel on November 27, 1869, in the constellation Pegasus, and appears to have been last observed on December 31 at Leipsic and Kremsmunster, the hope of seeing it after the next period of moonlight not having been verified. On November 29 Dr. Vogel, observing at Leipsic, described it as a very faint large object elongated in the direction of the declination circle: in the comet-seeker its diameter was about 6′. On December 7 it was still very faint, large, and elongated in the direction 300°, the central condensation very slight. On the following night its diameter was 5′, it had "a peculiar milky appearance" and hardly any central condensation, so that observations were attended with difficulty. On the 21st it was seen only with much exertion of the eye, but on the 31st, though the comet was very faint, Prof. Bruhns considered his separate comparisons certain to about ten seconds of arc. At Kremsmunster Prof. Strasser found it "extraordinarily faint" during its entire visibility, and in consequence of wanting central condensation, very difficult to observe, and hence considered that his positions would not possess the ordinary degree of accuracy. The elements of the orbit were calculated by Tiele, Oppolzer, Schulhof, and Bruhns, the parabolic orbit published by the latter in No 1788 of the *Astronomische Nachrichten* being founded upon nearly the whole extent of observation, he remarks with respect to it:—"Eine angestellte Vergleichung hiesigen Beobachtungen scheint aber doch auf eine Abweichung der Bahn von der Parabel hinzudeuten . . " We are not aware that any further examination of this point was made. If the period of revolution be really something less than eleven years, the circumstance of the comet having escaped observation prior to 1869 will not nevertheless occasion surprise, considering that both in 1869 and 1880 it has approached near the earth and has yet been very faint and diffused, so that when the perihelion passage has occurred at other seasons of the year it might be beyond reach of the telescope. It will be most essential for the theory of the comet's motion that observations should be continued as long as possible at the present appearance, that if it prove to be one of short period its next return to perihelion may be closely predicted · the computation of the planetary perturbations during the period 1869-80 will of course be a necessary process with this object in view.

THE STAR LALANDE 1013-4.—Mr. G. Knott has examined this star, to which we lately drew attention, as being credited with the very discordant magnitudes 5, 7·7, and 10. He writes from Cuckfield on November 21: "I looked the star up on November 8 and again on November 19, and found it on each occasion 7 9 mag, and sensibly equal to B.D. + 51°, No 131, which forms a convenient comparison star This estimate, it will be seen, agrees nearly with that in the *Durchmusterung*; Harding marks the star 6m.

CHEMICAL NOTES

IN the last number of the *Berichte* of the German Chemical Society Herr v. Lippmann describes experiments which show that a solution of pure cane sugar, when charged with carbon dioxide, is slowly converted into inverted sugar. If the carbon dioxide be pumped into the sugar solution under pressure, the rate of inversion is considerably increased: at 100° the inversion takes place rapidly.

IN the *Annales Chim. et Phys.* the results of M. Raoul's experiments on the freezing points of alcoholic liquids are detailed. An aqueous solution of alcohol containing 1·6 per cent. by volume freezes at − 0·5; a solution containing 47 9 per cent. freezes at − 32°. The freezing point of solutions containing from 24 to 51 gram alcohol per 100 grm. water is decreased by 0°·528 for each gram of alcohol: when more than 51 grm. alcohol are present to 100 grm. water no regular decrease in the freezing point was observable. The freezing points of various wines are given in the paper referred to.

IN *Comptes rend.* M Kessler announces that he has prepared a crystallised hydrate of hydrofluosilicic acid, viz., $H_2SiF_6 . 2H_2O$. The hydrate is a hard, colourless, very deliquescent solid, which fumes strongly in air, and melts at about 19°.

IN the same journal M. de la Source describes his experiments on the dialysis of ferric oxide dissolved in a solution of ferric chloride. "Fer Bravais" of medicine consists of $30Fe_2O_3 . Fe_2Cl_6$; after three months' dialysis of a dilute solution of this substance the greater part of the chlorine had passed into the dyalysate, the proportion of ferric oxide to chloride was then $116Fe_2O_3 . Fe_2Cl_6$, and the chlorine yet continued to pass through the dialyser. The author thinks that ferric hydrate is, *per se*, under certain conditions soluble in water.

HERR A. HERZEN describes in *Biol. Centralblatt* some experiments on acetous fermentation. In each of three flasks was placed 100 c.c pure water, to the first flask 10 per cent. pure alcohol and a drop from the surface of a fermenting wine full of *Mycoderma aceti* were added, to the second flask were added 5 per cent. of pure acetic acid and a drop of the fermenting wine, and to the third flask were added 5 per cent. acetic acid, 5 per cent. of a saturated solution of boric acid, and a drop of the fermenting wine. After eight days at 25° no *Mycoderma* appeared in the first flask, much appeared in the second, and a little in the third. Hence the author concludes that *Mycoderma aceti* lives at the expense of acetic acid already formed in wine, and that it does not cause the transformation of alcohol into acetic acid, but that it is rather a consequence of this chemical change; further, that boric acid retards the development of *Mycoderma*, but does not prevent it in presence of already-formed acetic acid.

IN *Dingler's Polytech-Journal* a paper appears by Drs Lunge and Schappi, on bleaching-powder The results confirm the now generally accepted formula first proposed by Odling, viz., CaOClCl.

IT was shown some time ago by H. T Brown that alcoholic fermentation proceeds more slowly under diminished than under ordinary pressure According to Boussingault (*Compt. rend.*), however, sugar is rapidly transformed into alcohol by the action of yeast, if the carbon dioxide and alcohol, as these are produced, be rapidly removed from the fermenting liquid. Addition of alcohol soon stops fermentation under ordinary circumstances, Boussingault shows that if the vessel containing the fermenting liquid be connected with an air-pump which is worked energetically, fermentation proceeds rapidly even when a considerable amount of alcohol has been added to the liquid.

IN connection with the recent liquefaction of ozone by Hautefeuille and Chappuis, the following numbers, from a paper by the same authors in *Compt rend.*, are of interest, as showing the exact influence of temperature and pressure on the ozonising of oxygen Diminution of pressure does not tend to increase the amount of ozone produced, but decreased temperature exerts a marked action in increasing the amount of oxygen transformed into ozone —

Tension of oxygen.	Tension of ozone				Proportion of ozone by weight			
	−23°	0°	20°	100°	−23	0°	20°	100°
760	108·70	82·84	53·96	—	0·214	0·149	0·106	—
380	51·68	38·76	31·54	1·43	0·204	0·152	0·125	0·0117
300	40·20	30·60	22·20	—	0·201	0·1525	0·112	—
225	24·80	22·95	15·52	0·088	0·191	0·151	0·104	0·0118
180	22·30	16·58	10·52	—	0·181	0·137	0·089	—

A DITTE describes in *Compt rend.* a number of new fluorine compounds of uranium, the most important are $UF_6 . 8HF$ and UO_2F_2, produced by the action of hydrofluoric acid on the oxide U_3O_8, when the former compound is heated in a closed platinum dish it melts, gives off hydrofluoric acid and small quantities of the oxyfluoride UOF_4, which compound is produced in larger quantity by heating the above mentioned oxyfluoride, UO_2F_2, in a closed vessel. The hexfluoride UF_6 is produced by heating the double salt $UF_6 . 8HF$ in an open crucible Various double salts are also described, the general formula being $UO_2F_2 . 4MF$, where M may be K, Na, Li, Rb, or Tl.

CLEVE has made a redetermination of the atomic weight of the very rare metal erbium (*Compt rend.*). Assuming the formula of the oxide to be Er_2O_3, the atomic weight of the metal is 166. Pure erbia, Er_2O_3, is a beautiful rose-coloured earth, slowly soluble in acids, having a specific gravity of 8·64, and forming salts characterised by a deep-red colour; several of these salts are described by Cleve.

THE same author has succeeded in separating nearly pure *thulium*; this metal and its salts are colourless, but solutions of the salts show two absorption bands, one strongly marked in the red, and one broad band in the blue. The atomic weight of thulium is 129·6 or 170·7, according as the metal is regarded as di- or tri valent.

PHYSICAL NOTES

IT is stated that amongst the recent discoveries of Prof. Bell in connection with the photophone research is the interesting fact that melted sulphur conducts electrically like selenium, but only at temperatures below that at which it thickens and becomes dark and viscid.

THE *Comptes rendus* for November 2 informs us that Prof. Graham Bell and M. Janssen have attempted to *hear* with the photophone the sounds believed to accompany the rapid commotions taking place in the solar photosphere The experiments were made at the Observatory of Meudon, a selenium cylinder being placed in different parts of an image of the sun some two feet in diameter. No very conclusive results were obtained, but M. Janssen has further suggested that a sort of concentrated effect might be obtained by passing a number of successive photographs of a sun spot across a beam of light, the variations of the intensity of the beam producing sounds when they fall upon the sensitive "photophonic pile" of selenium. Some experiments in furtherance of this suggestion are now proceeding.

HAVING undertaken a series of researches upon the rapidity of evaporation of liquids, in dependence from the cohesion of molecules on their surfaces, M. Sreznevsky has measured how this rapidity varies with the variations of the height of the meniscus. He has established that, the diameter of the meniscus remaining invariable, the rapidity of evaporation increases as the height of the meniscus diminishes, that is, as its radius increases. There is however an anomaly as to this last law for distilled water: when the evaporation is measured in a meniscus the height of which is greater than the radius of its basis, the rapidity of evaporation increases throughout, however the radius of the meniscus begins by diminishing, and increases only after having passed through a minimum, but this minimum does not have a corresponding minimum in the rapidity of evaporation.

AT the recent meeting of the Helvetic Society of Natural Sciences M. Forel described a *thermal bar* which is developed in winter parallel to the shore of a lake of fresh water, and which separates the pelagic from the littoral region. The water of the former region remains long, and in some lakes always, at a temperature above 4° C, in the littoral region, if the winter be cold, the temperature descends between 4° and zero; and between the two there is a band of water at 4°, descending to the bottom —a kind of mountain with crest parallel to the shore and a talus on either side.

M. DUFOUR described at the same meeting an apparatus for indicating the variations of chemical intensity of the sunlight. It has some likeness to Draper's tithonometer; the principle is, opposing the variable action of light on a mixture of chlorine and hydrogen, with an electric current (of variable intensity, and measurable each instant), which by its passage causes decomposition of a quantity of hydrochloric acid equal to that produced by action of the light on the mixture of chlorine and hydrogen. The apparatus is like a Rumford differential thermometer; in one bulb is some hydrochloric acid solution, with carbon electrodes, in the other some sulphuric acid. The light acts on the former One mode of measurement is to note the time taken in displacement of the sulphuric acid column a certain distance along the connecting tube Then bring back the column to its original position by passing the current.

M PICTET has lately made experiments (*Arch. de Sci.*) as to the dissolving power of gases and vapours on one another. Various solutions of alcohol and water were successively put into one of two glass balloons connected by a tube; pressure was diminished with an air-pump, so that the space became filled with vapours from the mixture. By closing the tapered point of the second balloon with the blowpipe, the apparatus allowed of distillation being effected with small differences of temperature. Plunging successively the balloon that held the solution in water at from 0° to 80°, and the other in water only 1° or a fraction of a degree below that of the liquid, M. Pictet got condensed products, the quality of which indicated what "affinity of solution" existed between water and alcohol. The following conclusions were arrived at: The weight of condensed liquid is proportional, in unit time, to

the *difference of temperature* between the liquid in ebullition and the condensed liquid. The weight of liquid condensed in unit time is independent of the interior pressure or of the mean temperature during distillation. Analysis shows that the gases have no power of solution on one another. M. Pictet was thus led to an industrial process for rectification of spirits.

GEOGRAPHICAL NOTES

AT the meeting of the Geographical Society on Monday, Sir Bartle Frere read what may best be described as a suggestive paper on Temperate South Africa as a route to the Central Equatorial Region. After defining the temperate region as the vast tract of country extending to Cape Frio on the Atlantic coast and to the mouth of the River Tugela on the opposite side of the continent, and giving a brief account of its geography, &c., Sir Bartle addressed himself chiefly to the task of pointing out how it could be made available as a base of operations in exploring the country north of the Zambesi, and suggesting agencies which might be turned to account for the extension of geographical knowledge. These agencies are the traders and hunters, who have a wide acquaintance with many regions otherwise unknown, and missionaries of various denominations. The latter have no less than eighty-four fixed stations beyond the colonial boundaries, manned by 812 Europeans, many of whom are highly cultivated and intelligent men, and have great opportunities for acquiring geographical information. Sir Bartle Frere also hoped that the Council of the Society might see their way to urging the Government to undertake a proper survey of the coast-line, as well as of the interior of the five colonies.

AT the meeting of the Berlin Geographical Society on November 6 the safe arrival of Dr. Lenz at Timbuctoo (by a route not before taken by any European) was announced. Two of his followers were lost in the desert, and two had gone back. Dr. Stecker (who lately went to Massowah with Herr Rohlfs) will, according to circumstances, either push through the Galla regions or to the East coast, or to the Great Lakes. Major v. Mechow reached a town on the Quanza, in the territory of the Hollo, about 200 km. from Malange on July 19, after great difficulties, especially in carriage of the boat. The natives were friendly throughout. A little above the place reached are the two last falls of the Quanza, between which is the mouth of the Cambo. The Major seems to have been the first white to visit these waterfalls. He was going to Lupung with a view to determine the course of the Quanza. Dr. Pogge and Lieut. Wissmann were also travelling in that region the same month, intending to reach Mussumba, the residence of the Muata Jambo; Dr. Pogge's object is to establish stations in the interior. Lieut. Wissmann will make journeys for topographical and collecting purposes. The Italian traveller, Dr. Matteucci, is seeking to reach Bornu from South Dar-For, going round Wadai and Bagirmi. *Inter alia* the Society resolved to memorialise the German Government to take part in the international project of systematic Polar investigation.

AT the sitting of November 19 of the Société de Géographie of Paris M. Zweifel received the palm of Officer of the Academy as a reward for the discovery of the sources of the Niger, in company with M. Marius Moustier. The laureate declining to speak himself, an address was delivered on behalf of him and his companions by Dr. Harmand, the well-known explorer of Cochin China. It appears that MM. Zweifel and Moustier saw a granite rock from which the powerful stream takes its rise, but they were not admitted to the site, owing to the high priest of Tembi Saleb, who inhabits an island situated on a small lake formed by the stream at a very few miles from its source. So something more remains to be done to complete the work begun by Laing, Reade, and Blyden.

SIR ALLEN YOUNG leaves England next month in his yacht, and will visit, among other places, the Canary Islands, a portion of the West Coast of Africa, and St. Helena, extending his voyage as far as the Cape, where he will make preparations and inquiries for a projected expedition of discovery to be undertaken by him to the Antarctic regions. It will be remembered that the *Erebus* and *Terror*, commanded by Sir J. Ross and Capt. Crozier, penetrated in 1841 to 78° 4′ S., a latitude which has never been reached before or since.

THE November number of *Petermann's Mittheilungen* has a long paper by Spiridion Gopčević, containing his ethnographical studies in Upper Albania. A very fine map embodies the important results of Severzov's exploration of the Pamir in 1878, with accompanying text, followed by an account of Lieut.-Col. Pjevzov's journey through Mongolia in 1878-9, to Kuku-Choto and Kalgan. A summary is given of the Arctic work of 1880, followed by the usual monthly notes.

THE first *Bulletin* of the recently-formed International Geographical Institute at Berne consists of a programme of the projected Italian Antarctic Expedition under Lieut. Bone, which is to leave Genoa in March 1881. A sketch is given of what has been previously done in this region, showing that the field is practically virgin so far as scientific work is concerned. The programme of the Italian expedition is very comprehensive, and the ultimate object is to pave the way for the establishment of an Antarctic observing station.

No. 3 of vol. iii. of the *Deutsche geographische Blätter*, the organ of the Bremen Geographical Society, contains the continuation of the unfortunate Dr. Rutenberg's journal in Madagascar, and the lecture given at the Danzig meeting of the German Association by Dr. Neumayer on "Polar Expeditions or Polar Research?" To the latter able lecture we referred last week, the point insisted on being that while the two are perfectly congruous, the former should be subjected to the latter, which must be carried out on the system of Polar observatories advocated by Weyprecht, and to which nearly every civilised nation adheres except England.

THE new number of the Marseilles Geographical Society's *Bulletin* contains a very voluminous account by Messrs. Zweifel and Moustier, of their expedition to the sources of the Niger. This memoir is illustrated by a map showing their route, and supplemented by an appendix containing information as to the natural resources of the country traversed, the races of the interior, &c.

THE last part of *Le Globe* contains a paper (with map) on the Island of Cyprus, by M. Paul Chaix, and some account of recent researches in the Pamir, furnished by M. Veniukoff.

IN the current number of *Les Missions Catholiques*, M. Armbruster has commenced a series of papers on Corea, drawn from information furnished from time to time by the Romish missionaries, the only Europeans who have ever had any opportunity of acquiring a real knowledge of the interior.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

OXFORD.—The preliminary examination in the Natural Science School begins on Monday next, November 29. The Final Honour School begins on Monday, December 6.

The Brakenbury Scholarship in Natural Science at Balliol College has been awarded to Mr. William Stroud, from Owens College, for proficiency in physics and chemistry. *Proxime accessit* Mr. A. D. Hall, from Manchester Grammar School. Mr. J. J. Hart, Manchester Grammar School, and Mr. J. E. Marsh of Balliol, are honourably mentioned.

ON A METHOD OF DETERMINING THE CRITICAL TEMPERATURE FOR ANY LIQUID AND ITS VAPOUR WITHOUT MECHANISM[1]

A PIECE of straight glass tube—60 centimetres is a convenient length—is to be filled with the substance in a state of the greatest purity possible. It is to contain such a quantity of the substance that, at ordinary atmospheric temperatures, about 3 or 4 centimetres of the tube are occupied by steam of the substance, and the remainder liquid. Fix the tube in an upright position, with convenient appliances for warming the upper 10 centimetres of the length to the critical temperature, or to whatever higher or lower temperature may be desired, and for warming a length of 40 centimetres from the bottom to some lower temperature, and varying its temperature conveniently at pleasure.

Commence by warming the upper part until the surface of separation of liquid and steam sinks below 5 centimetres from the top. Then warm the lowest part until the surface rises

[1] By Sir William Thomson, British Association, Swansea, Section A, Tuesday, August 31.

again to a convenient position. Operate thus, keeping the surface of separation of liquid and solid at as nearly as possible a constant position of 3 centimetres below the top of the tube, until the surface of separation disappears.

The temperature of the tube at the place where the surface of separation was seen immediately before disappearance is the critical temperature.

It may be remarked that the changes of bulk produced by the screw and mercury in Andrews' apparatus are, in the method now described, produced by elevations and depressions of temperature in the lower thermal vessel. By proper arrangements these elevations and depressions of temperature may be made as easily, and in some cases as rapidly, as by the turning of a screw. The dispensing with all mechanism and joints, and the simplicity afforded by using the substance to be experimented upon, and no other substance in contact with it, in a hermetically sealed glass vessel, are advantages in the method now described. It is also interesting to remark that in this method we have continuity through the fluid itself all at one equal pressure exceeding the critical pressure, but at different temperatures in different parts, varying continuously from something above the critical temperature at the top of the tube to a temperature below the critical temperature in the lower part of the tube.

The pressure may actually be measured by a proper appliance on the outside of the lower part of the tube to measure its augmentation of volume under applied pressure. If this is to be done, the lower thermal vessel must be applied, not round the bottom of the tube, but round the middle portion of it, leaving, as already described, 10 or 20 cms. above for observation of the surface of separation between liquid and vapour, and leaving at the bottom of the tube 20 or 30 cms. for the pressure measuring appliance.

This appliance would be on the same general principle as that adopted by Prof. Tait in his tests of the *Challenger* thermometers under great pressure (*Proceedings*, Royal Soc. Edin., 1880), a principle which I have myself used in a form of depth-gauge for deep-sea soundings, in which the pressure is measured, not by the compression of air, but by the flexure or other strain produced in brass or glass or other elastic solid.

ABNORMAL VARIATIONS OF BAROMETRIC PRESSURE IN THE TROPICS, AND THEIR RELATION TO SUN-SPOTS, RAINFALL, AND FAMINES

IN the first part of his work on the Meteorology of the Bombay Presidency, which was submitted to Government in August, 1875, Mr. Charles Chambers pointed out that the variation of the yearly mean barometric pressure at Bombay shows a periodicity nearly corresponding in duration with the decennial sun-spot period (see "Meteorology of the Bombay Presidency," § 26, p. 12), and in August, 1878, in a letter to NATURE, vol. xviii. p. 567, I drew special attention to this relation, pointing out that the observations of the winter and summer half-years, separately as well as conjointly, show that the pressure is low when the sun-spot area is great, and *vice versâ*, but that the pressure curve *lags behind* the sun-spot curve.

In November of the same year the eminent physicist, the late Mr. John Allan Broun, regarding the relation thus established between the variations of barometric pressure and sun-spots as one of very great importance, in that it gave a probability to the existence of similar laws in the variations of other meteorological elements which he believed was previously wanting, communicated to the same periodical (NATURE, vol. xix. p. 6) an article in which he showed, from the observations recorded at Singapore, Trevandrum, Madras, and Bombay, that the years of greatest and least mean barometric pressure are probably the same for all India, and from this he inferred that the relation to the decennial sun spot period found for Bombay holds for all India.

In December, 1878, Mr. S. A. Hill supplemented and confirmed Mr. Broun's communication by giving similar data for Calcutta (NATURE, vol. xix. p. 432).

In May, 1879, Mr. E. D. Archibald communicated to NATURE, vol. xx. p. 28, the fact (brought to his notice by Mr. S. A. Hill) that at St. Petersburg the mean annual barometric pressure is high when the sun-spots are numerous, low when they are few, but that the pressure epochs lag behind the sun-spot epochs.

In December of the same year Mr. Blanford presented to the Asiatic Society of Bengal a paper (*Journal* of the Asiatic Society of Bengal, vol. xlix. part ii. 1880, p. 70) in which it was shown that the barometric observations recorded at Batavia from 1866 to 1878, at Akyab, Chittagong, and Darjeeling from 1867 to 1878, at Port Blair from 1868 to 1878, and at Singapore from 1869 to 1878, afford more or less confirmation of the results previously obtained for other stations in India.[1] And in the same paper Mr. Blanford brought forward the observations recorded at the Russian observatories at Ekaterinburg, Slatoust, Bogolowsk, and Barnaul from 1847 to 1877, and showed that at the two former stations during the whole period, and at the two latter during the first half of it, the barometric variations were similar to those previously obtained by Mr. Hill for St. Petersburg.

In a subsequent letter to NATURE, published in March, 1880, Mr. Blanford discussed the same observations in greater detail, dealing with the summer and winter observations separately, as well as conjointly, and showed that the decennial variation of the barometric pressure found for St. Petersburg was exhibited only by the observations of the winter months. He also obtained similar results for Ekaterinburg and Barnaul, but he appears to have overlooked the very important facts that the range of the winter curves rapidly decreases in passing from St. Petersburg, through Ekaterinburg to Barnauland, that the summer curves for the two latter stations are, on the whole, of the *same* character as the summer curves of the Indian stations, as may be seen by comparing the dotted curves for Ekaterinburg and Barnaul, given in NATURE, vol xxi p. 48, with the summer curve for Bombay, given in vol. xviii. p. 568 of the same periodical. He also showed that the barometric curves for Batavia, Singapore, and Port Blair were, as at other Indian stations, of the same character both in winter and summer.

In 1873 and 1874 (see British Association Reports for those years) Mr. Meldrum showed that there was strong evidence of a connection between sun-spots and rainfall, and he has recently (see *Monthly Notice* of the Meteorological Society of Mauritius for December 1878) put this question beyond all reasonable doubt by showing that the mean yearly rainfall of Great Britain, the continent of Europe, America, India, and the Southern Hemisphere, varies in the same way as the sun-spots, being on the average great when they are numerous, small when they are few.

In my "Brief Sketch of the Meteorology of the Bombay Presidency"[2] in 1876, I pointed out that the abnormal variations of the monthly mean barometric pressure in that year were mainly variations in the intensity of the usual seasonal movements, although at least some portion of the variations influenced a wider area than the Indian monsoon region, and in the Sketch for 1877 I attributed the uniformly high barometric pressure and the deficient rainfall of that year to a weak development of the equatorial belt of minimum pressure, probably induced by a diminution of the solar heat.

In the Report on the Meteorology of India in 1877 Mr. Eliot showed that the high pressure of that year was a characteristic of the whole Indian area and also of Australia.

In my meteorological sketch for 1878 I showed that the abnormal barometric movements observed at Zi-ka wei in China and at Manilla in 1878 were similar to those recorded in Western India; that the latter largely influenced the rainfall of the Bombay Presidency, and that in former years of deficient rainfall at Bombay the barometer had been relatively high, not only at Bombay, but also at Mauritius and Batavia.

In the paper (*Journal* of the Asiatic Society of Bengal, vol. xlix. part ii., 1880, p. 70) already quoted, Mr. Blanford has confirmed the fact that the excessive pressure observed in the Indian area in the years 1876 to 1878 extended to China and Australia, and he has also shown that it affected Western Siberia also.

In my sketch for the year 1879 I have shown that these uniform variations of barometric pressure are accompanied by a nearly uniform variation of the percentage rainfall of all portions

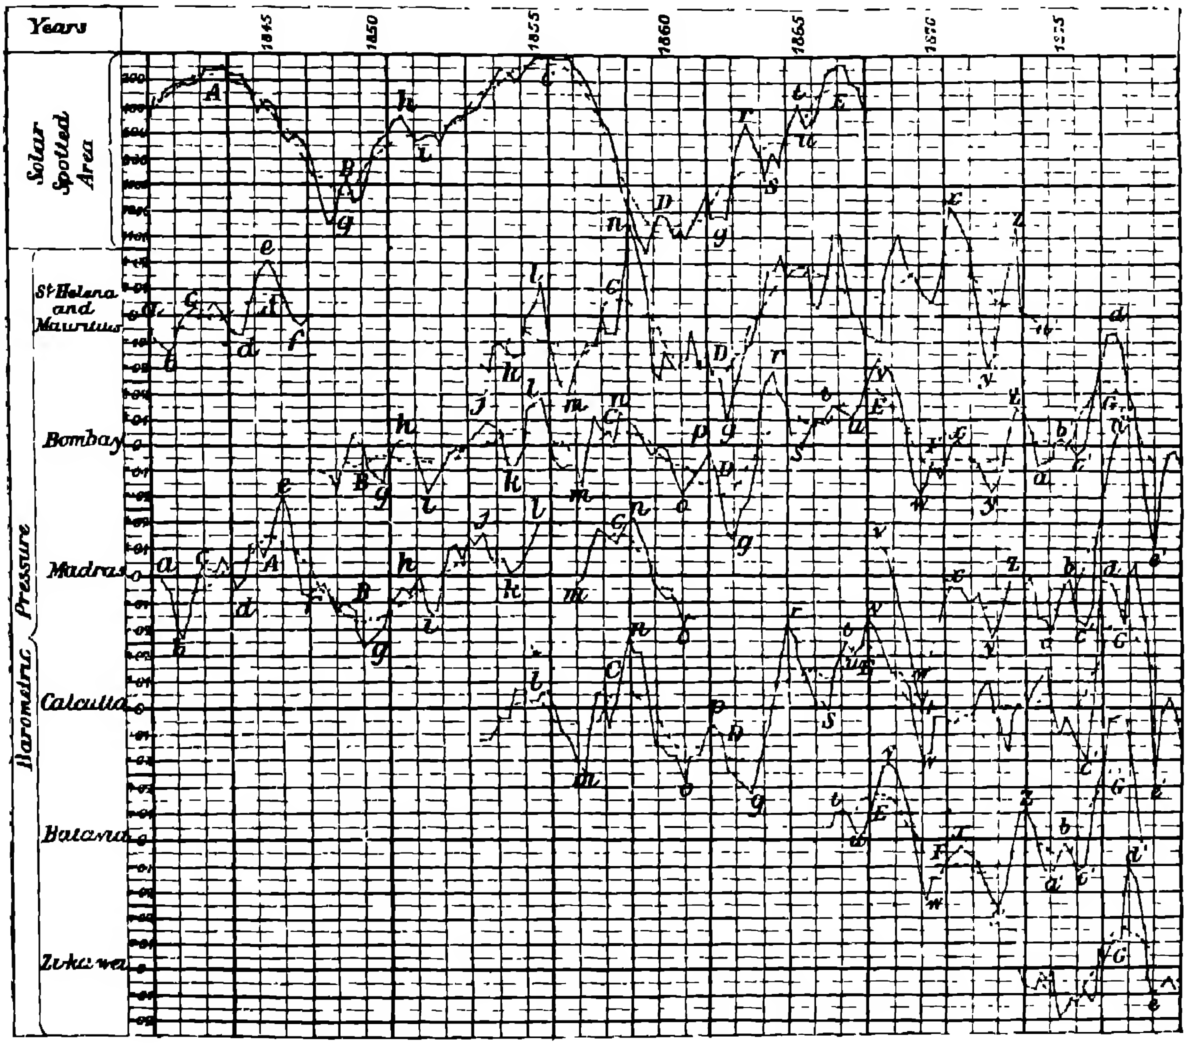
[1] During the first half of these periods the results for Singapore, Akyab, Chittagong, and Darjeeling differ so much from each other and from the remarkably accordant results obtained from the more widely separated stations of Bombay, Calcutta, Port Blair, and Batavia as to suggest that the former are of doubtful validity during the earlier years.

[2] These sketches are submitted annually to Government in August of the year following that to which they refer. See notices in NATURE, vol. xviii pp. 199 and 619, vol xxi p. 384. The sketch for 1879, containing some further important conclusions with reference to the variations of rainfall and barometric pressure, has recently been submitted to Government.

of the Bombay Presidency, and that the proportionate increase or decrease of the abnormal rainfall, corresponding to a fall or rise in the abnormal pressure of a tenth of an inch of mercury, amounts to more than *one hundred per cent.* of the normall fall, but that the variations of the ordinary monsoon gradients produce very different effects on the rainfall of different districts, depending on the geographical peculiarities of the particular locality.

From all these facts it is clear that there is some intimate relation between the variations of sun-spots, barometric pressure, and rainfall; and as famines in general are induced by a deficiency of rain, it is probable that they also may be added to the above list of connected phenomena. What is required in order to gain an insight into the causal relation of these variations is that they should each and all be studied in greater detail than has hitherto been attempted. Accordingly I commenced, more than a year ago, a detailed investigation into the nature of the abnormal variations of barometric pressure, and have been led to the discovery of some new facts which appear to me to be of sufficient importance to render it desirable that they should be published in anticipation of the theoretical conclusions deducible therefrom.

Commencing with the daily abnormal barometric variations observed at several stations in Western India, it was soon found that as the time over which an abnormal barometric fluctuation extended became longer and longer, the range of the fluctuation became more and more uniform at the various stations, thus leading to the conclusion that the abnormal variations of long



duration affect a *very wide area*. To test this inference it became necessary to compare the observations recorded at Bombay with those of some distant tropical station. Batavia was chosen, and on curving the daily observations side by side with those of Bombay, the degree of accordance between them was found to be truly surprising, considering how far the two stations are apart. The next step was to compare the monthly abnormal variations of these two stations, and finding that they presented many similar features, as well as some differences, to smooth the variations by taking three-monthly means. The degree of accordance was now found to be still greater, many of the discordances having been eliminated in the process of smoothing; but as some differences were still observable the process was repeated, giving nine-monthly means of abnormal pressure corresponding to the middle of the months January, April, July, and October of each year. The curves obtained in this way for Bombay and Batavia were then found to be *almost identical in form*, but with this very remarkable difference: *the curve for Batavia was seen to lag very persistently about one month behind the Bombay curve*. Similar results were then worked out from all the available data for the following tropical stations: St. Helena, Mauritius, Madras, Calcutta, and Zi-ka-wei, and for comparison with them the monthly sun spot areas[1] were treated in exactly the same manner. The results are given in the following table, and graphically represented by the continuous curves on the annexed plate:—

[1] Taken from the paper by Messrs De La Rue, Stewart, and Loewy, published in the *Philosophical Transactions* for 1870, p. 122.

TABLE I.

Nine-Monthly Means of Solar Spotted Area and Abnormal Barometric Pressure

Year		Solar spotted area in millionths of visible hemisphere	Abnormal barometric pressure in thousandths of an inch					
			St. Helena	Bombay	Madras	Calcutta	Batavia	Zi-ka-wei
1841	1	473	- 5					
	2	354	- 8					
	3	359	- 12		- 1			
	4	285	- 14		7			
1842	1	241	- 11		- 18

Comparison of Abnormal Barometric Movements at Different Stations.—The general resemblance of all these curves to each other is very remarkable, indeed if the Mauritius curve for the years 1867 and 1868 be excluded, there is scarcely a single prominent feature in any one of the curves which is not reproduced in the others. To show this the corresponding points of the different curves have been marked with the same small letters It will be seen, however, that there is strong evidence of a want of exact simultaneity in the barometric movements at different stations, and that as a rule the changes take place at the more westerly stations *several months earlier* than at the more easterly ones. This is particularly noticeable in the curves for St. Helena and Madras from 1841 to 1846, when the latter sometimes lagged behind the former by as much as six months, in those for Mauritius and Calcutta from 1855 to 1866, when the latter persistently lagged several months behind the former, in those for Bombay and Calcutta from 1862 to 1866, when the difference in time often amounted to *upwards of six months*, in those for Bombay and Batavia from 1867 to 1878, when (as already remarked) the latter lagged behind the former at an average interval of about one month, and in those for Bombay and Ti-ka-wei from 1876 to 1878, when the latter lagged upwards of six months behind the former. *It appears then that these long atmospheric waves (if such they may be called) travel at a very slow and variable rate round the earth from west to east, like the cyclones of the extra tropical latitudes*

Bombay FRED. CHAMBERS

(*To be continued*)

DR SIEMENS'S NEW CURE FOR SMOKE

FROM among a number of letters which have been sent us on this subject we have selected the following for publication, to these Dr. Siemens has been good enough to append some important remarks

IN NATURE, vol xxiii. p. 25, I read with interest an article by Dr. Siemens describing an ingenious gas and coke fire which he suggests as a cure for the smoke nuisance. But although the darkening of the atmosphere or fog will certainly be prevented by its use, I am afraid the *gases from the coke*, especially the carbonic oxide, will make the fogs at least as poisonous and injurious to health as the open coal fires at present in use.

In these circumstances a description of an "Asbestos gas fire" free from this objection, which we have had in use in our smoking room for the last three years, and which, after a few alterations, has proved perfectly satisfactory, may perhaps interest your readers.

A ½-inch gas-pipe furnished with four Bunsen burners is laid on the hearthstone under the grate and parallel to the ribs, so arranged that the tops of the burners (which are made elliptical to pass through the bars) are flush with the upper surface of the grate, and two inches back from the line of the ribs. The fire-place is loosely filled with a preparation of asbestos in pieces about the size of a hen's egg.

This fire not only evolves a large amount of heat, but has a very cheerful appearance, similar to that of a bright coke fire, and to insure this it is essential that the burners should be placed close to the ribs, as stated above, and not in the centre of the grate. If this is not attended to the asbestos in the centre of the fire will be raised to a high temperature, but will not be sufficient to heat those portions in front, which will then not only be of no use as radiators in themselves, but act as screens to the light and heat generated in the centre. I suspect this was the cause of the failure of Dr. Siemens' pumice gas fire.

The cost of maintaining this fire is simply that of the amount of gas burned, as the asbestos is not consumed, and its prime cost is trifling I have only further to add that there is not the slightest trace of fumes or smell from the fire two minutes after it is lighted. D. A. STEVENSON

Edinburgh, November 15

DR. SIEMENS has described in your pages the form of coke-gas grate which he has fitted in his own house. As I had fitted a similar arrangement in this house before Dr. Siemens' letter appeared in the *Times* of November 3, and as it is simpler than Dr Siemens' and succeeds even beyond my expectation, I send you a drawing and description of it. It varies, of course, according to the shape of the grate in which it is fitted, but for the sake of comparison I have copied Dr. Siemens' grate, and drawn my arrangement as fitted into it

Instead of Dr. Siemens' arrangement for withdrawing the heat from the back of the fire and bringing it to the front, I merely line the whole grate—sides, back, and bottom—with fire-bricks This obviates the necessity for the close-fitting ash-pan described by Dr Siemens, which would be rather expensive to fit. I make the fire-brick in the bottom of the grate slope towards the front, and leave a space of one inch between the front of it and the perforated gaspipe down which space the ashes fall on to the hearth.

If my grate is not quite so economical in working as Dr. Siemens', it is very near it, and the first cost of fitting is considerably less. In fact, as most grates are lined with fire-brick at back and sides, nothing has to be done but fit a wedge shaped fire-brick into the bottom, a half-inch iron gaspipe, perforated with holes in front, and connect it with the gas service, all of which can generally be done for a few shillings.

The saving of kindling wood and of chimney-sweeping would pay for it in a year. In Dr Siemens' grate the copper must cost about *1l* A grate fitted with this arrangement looks exactly the same as an ordinary grate, and there is nothing to prevent ordinary coal being burnt in it—in fact coal can be burnt in it with much less smoke than in an ordinary grate by turning on the gas for a few minutes when fresh coal is put on, when the dense black smoke emitted by the new coal is completely burnt up in the gas flame. To people who object that a gas grate must produce a bad smell in the room I can only say, "Come and see." They will find that we have three grates with this arrangement in constant use in these chambers, and that they produce no smell and make a very pleasant fire. Any person who takes an interest in the subject is quite welcome to come in and look at them at any time. COSMO INNES

Adelphi Chambers, 7, John Street, Adelphi

HAVING been experimenting for some years in the direction referred to by Dr. Siemens in NATURE, vol xxiii p. 25, I must beg to differ with him most seriously in some of his conclusions. The gas-fire with coke which he describes has, so far as our experience goes, several practical objections which prevent its use in the place of an ordinary gas fire, whilst when compared with a *good* coal fire it fails seriously.

First, with regard to the objections to Dr. Siemens' fire. It requires about half an hour to become anything like warm, as against ten to fifteen minutes with a well-lighted coal fire. Second, it makes as much or more dust and dirt than a *good* coal fire Third, the grate requires as much cleaning and care as with coal

I am not surprised at the economy, comparing the coal fire as shown with gas and coke, but if the result had been taken in

comparison with a good Abbotsford grate with solid clay bottom, back and sides, the figures would have appeared seriously the other way.

In a room of exactly half the cubic area of the one referred to by Dr Siemens we have an Abbotsford grate a little over ⅓rd cubic foot capacity, the actual measurement of the fire space being 5½ inches deep, 8 inches back to front, 14 inches wide. This is lighted at 7 o'clock every morning and at 10 o'clock the grate is filled (not piled high). This fire burns until 10 or 11 o'clock every night untouched, practically smokeless, making the room pleasantly warm all over in the severest weather, and without making a *handful of cinders in a month*. One ordinary boxful of coals lasts two days. We have five, sometimes six, fires going daily at an average cost for coal for the winter season of five shillings weekly, or less than twopence per day per fire That Dr. Siemens is correct so far as the old style of fire grate is concerned, I know to my cost, but taking any good grate with clay sides and back and a solid clay bottom, his fire at its best will not compare either for cleanliness, economy, or comfort.

Gas fires are wanted where absolutely no attention and dust can be permitted. Allowing either of these as possible, no substitute I know will approach a well-constructed open fire with a solid clay bottom and fire-box

With regard to the waste heat, it is no greater than absolutely necessary to take away the products of combustion, as, with our grates, it is utilised for warming the upper rooms. At this moment, with five good fires, there is visible from the tops of our chimneys nothing except a clear transparent current of warm air, any one at a cursory glance would say there were no fires in the house.

It must be borne in mind when I refer to cost that we cook entirely by gas, and the price of good coal here is 14*s*. 2*d*. per ton, coke being about half this price. What is required in a gas fire is a perfectly clean source of radiant heat, without trouble, and quickly available these conditions are not in any way fulfilled by Dr. Siemens' arrangement. With the exception of two or three minutes expended in lighting, all he has attained can be found in a more perfect form in many of the fire-grates which have been in common use for the last ten years Amongst our many attempts at gas fires one, although not absolutely the same as Dr. Siemens', was practically so, and was condemned because it required as much trouble as our present fires, and was much slower in lighting It would be both interesting and instructive if Dr. Siemens would test an Abbotsford grate under the same conditions as his coke gas fire, and supplement his report with one from the individual who has to do the cleaning up and dusting, a department which it is more than probable he ignores

Another important matter is that I believe the cost of making and fixing Dr Siemens' grate would be not less than that of a good modern fire-grate. THOS. FLETCHER

Warrington

THROUGH your courtesy I am enabled to reply to the objections raised by three correspondents against my proposed gas-coke grate, before they have actually appeared in your columns.

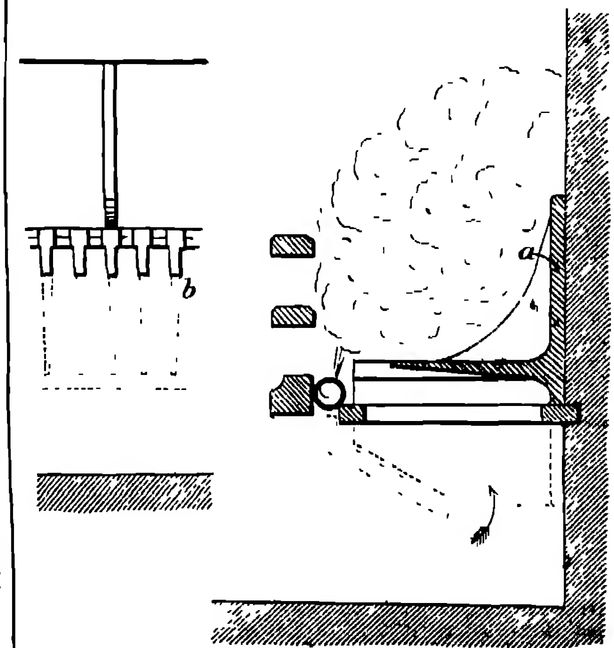
Mr. D. A. Stevenson considers that the use of coke is objectionable on account of the gases evolved in its combustion, and especially the carbonic oxide gas, which would poison the atmosphere. In reply I have to say that in burning coke with a supply of hot air, and in contact in front of the grate with the atmosphere, its entire combustion is insured, resulting in carbonic acid, which is a necessary constituent of our atmosphere In obtaining the same amount of heat through the perfect combustion of gas, products of combustion at least equally objectionable from a sanitary point of view will be evolved.

The gas-asbestos grate which he describes appears to be judiciously contrived, but its power of heating the room depends entirely upon the combustion of gas unaided by hot air or solid fuel. Now 1000 cubic feet of gas weigh about 34 lbs., and the heat developed in the combustion cannot exceed $34 \times 22{,}000 = 748{,}000$ units of heat.

The heat units produced in burning a pound of coke may be taken at 13,400 (assuming it to contain about 8 per cent. of incombustible admixture, the heat equivalent of pure carbon being 14,500 units), and it requires $\frac{748{,}000}{13{,}400} = 56$ lbs., or just half a hundredweight of this coke, to produce the heating effect of 1000 cubic feet of gas.

Taking gas coke at 18*s*. per ton (which is an excessive price), the 56 lbs. of coke represent a cost of 5·4*d*., as compared with 3*s*. 6*d*. for the 1000 cubic feet of gas producing the same amount of heat. This great difference of cost at once shows the advantage of making coke do as much of the work as possible. Without it a gas grate will consume 50 to 70 cubic feet of gas per hour, whereas my experiments prove that an average consumption of 8 cubic feet suffices to heat a large room when combined with a moderate consumption of coke, and with the use of the heating arrangement, to which I attach great importance. Another important consideration in favour of the joint use of coke and gas is that the existing gas companies produce both these constituents very much in the proportion in which they would be required, and could therefore provide the means of supplying an enormous number of coke-gas grates, whereas their plant and mains would be quite inadequate to supply a demand upon them for an extended application of purely gas stoves.

Mr. Cosmo Innes describes a gas grate of his construction, having the closed grate and single gas pipe behind the lower front bar which I advocate; he proposes to fill the grate with common coal, using the gas only as a means of kindling the fire. My objections to his proposal are that in using coal he must continue to make smoke, which we are desirous to prevent, and that the hot back to his fire means rapid distillation of the fuel up the chimney in the form of hydrocarbons and carbonic oxide. The gas arrangement as shown by him will be efficacious, no doubt, as a means of kindling a bright and cheerful fire, but he



would do better in that case to use a few logs of wood instead of coals A bright but short-lived fire may thus be raised quickly at a cheap rate in a dining-room or in a parlour.

Mr. Thomas Fletcher admits that my grate has the advantage of economy over a common coal grate, but thinks the Abbotsford grate the best of all. This grate is according to him practically smokeless, and produces only a handful of cinders in a month, although common coal is used Now I have no desire to detract from the merits of the Abbotsford grate, but I fail to see why it should be smokeless, considering that raw coal is used; and the extremely small production of ashes or cinder seems to imply that Mr. Fletcher uses an extremely pure and probably a smokeless coal, very different from the fuel we are usually supplied with in London.

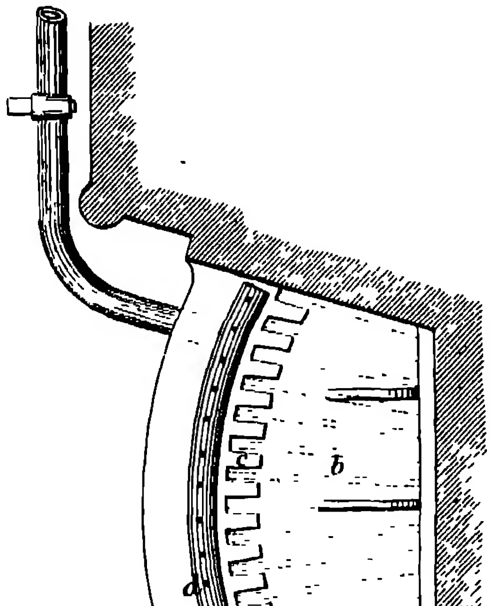
He also objects to the cost of my arrangement, and his opinion in this respect, coming from a practical grate-builder, is entitled to every consideration. In first describing my plan I did not go into the question of cost of application; but having been since asked by grate-builders to advise them regarding the cheapest form of my grate and the easiest mode of applying it to existing fire-places, I have devised a form of application which leaves little to be desired, I think, as regards first cost.

The arrangement is shown by the accompanying sketch, and consists of two parts which are simply added to the existing

grate, viz.:—(1) the gas-pipe (d) with holes of about $\frac{1}{16}$ inch diameter, 1·5 inch apart along the upper side inclining inward, and (2) an angular plate (a) of either cast or wrought iron, with projecting ribs (b) extending from front to back on its underside, either cast with or riveted to the same, presenting a considerable area, and serving the double purpose of supporting the additional part on the existing grate, and of providing the heating-surface produced by the copper plate and frill-work in my first arrangement. In using iron instead of copper it is necessary however to increase the thickness of these plates and ribs in the inverse ratio of the conductivity of the two metals, or as regards the back plate, from $\frac{1}{4}$ inch to $\frac{5}{8}$ inch.

The arrangement will be rendered more perfect by the use of the bent plate fastened to the lower grate bar, which directs the incoming air upon the heating surfaces.

The front edge of the horizontal plate has vandyked openings (c), so as to form a narrow grating, through which the small quan-



tity of ashes that will be produced by combustion of the coke and anthracite in the front part of the grate discharge themselves down the incline towards the back of the hearth, where an open ash-pan may be placed for their reception.

In adapting the arrangement to new grates, the horizontal grating had better be dispensed with, and the casting with its lower ribs extended downwards, so as to find its fixed support between the back of the fireplace and the inclined deflector plate.

Mr. Fletcher speaks of the large amount of ashes that would be produced, but this amount can surely not be as great as in the case of a coal fire, seeing that the consumption of solid fuel is reduced to less than one-half, of which nearly one-half is anthracite, a fuel remarkably free from ashes. Neither do I participate in Mr. Fletcher's fear regarding opposition on the part of housemaids, except it be from an apprehension on their part that, with Othello's and the chimney-sweeps', their "occupation be gone."

The tendency of grate-builders of the present day, and also of your correspondents, appears to be to look for economy to brick-linings, which no doubt have the effect of producing hot radiating surfaces. I maintain however that such radiation is obtained at too great a cost of fuel, and that superior economical results will, on the contrary, be attained by abstracting the heat from the back of the fire, and concentrating it upon the purely carbonaceous material in front of the same.

To illustrate my reasoning I may here refer to an experiment which can easily be made of throwing a shovelful of bituminous coal into a steel-melting furnace; the result is an instantaneous dispersion of the coal, accompanied with a powerful refrigerative action on the furnace. In constructing gas-producers I take advantage of hot walls to turn solid into gaseous fuel, and a fireplace with hot brick bottom and sides is very much in the condition of a good gas-producer, giving out radiant heat no doubt, but combined with rapid distillation of combustible gases into the chimney. This action is made apparent in placing on the fuel towards the back of such a grate when in full glow a piece of wood, which will be seen to dwindle away rapidly without giving rise to flame, the atmosphere immediately over the glowing fuel being essentially a reducing one.

In my grate the heat, on the contrary, is confined to the coke immediately behind the bars, in contact with the heating gas flames and with the air of the room flowing in towards the chimney, whereas the coke at the back of the grate remains comparatively cool and unconsumed throughout the day. The cold furnace back also means a cold chimney, and it is rather remarkable to observe that in the case of the application at my office, a thermometer held high up into the chimney showed a temperature of only 130° F., while the front of the grate was in a high state of incandescence. These, I maintain, are conditions most favourable to economy combined with entire absence of smoke or deleterious gases. C. WILLIAM SIEMENS

12, Queen Anne's Gate, S.W., November 24

CURIOUS IMPRESSIONS IN CAMBRIAN SANDSTONE NEAR LOCH MAREE

IN course of the short excursion to Loch Maree and its neighbourhood, Mr. Walter Carruthers, of the *Inverness Courier*, happened, on June 13, to light upon an interesting portion of the Cambrian or Torridon Red Sandstone of the district, forming part of the bed of the burn, near Loch Maree Hotel, on which occur what have been called the Victoria Falls, so named from the fact that the Queen visited them. There an exposed surface of the rock about sixteen feet in length, nearly as much in breadth, and almost perfectly level, is marked by several double grooves quite discernible, and each divided by a very thin raised line. These traverse the whole length of the rock in a perfectly straight line, and on both sides of them are roughnesses which, if we could entertain the idea that the grooving had been caused by some living creatures, might be produced by footprints which have been to a great extent obliterated. The impressions were so striking that they immediately suggested a recollection of the footprints discovered in the sandstones of Morayshire and Tarbatness, though there was no other resemblance than their marked character on the broad, flat rock. Having heard that Mr. William Jolly, H.M. Inspector of Schools, was in the neighbourhood, Mr. Carruthers called his attention to the subject, and indicated where he should find the markings. Mr. Jolly was not slow to examine the spot, and he writes to Mr. Carruthers as follows, as given in the *Inverness Courier* of July 1:—

"I found your curious lines without difficulty, guided by your accurate description of their locality. They are assuredly no 'mare's nest,' but *bonâ fide* ancient impressions of some kind, which should receive the attention of geologists, both on their own account and as existing in the second oldest geological formation in Britain, in which, as yet in Scotland, no evidences whatever of organic life have been discovered.

"The lines or bands in question occur in the chocolate-coloured Torridon sandstone, the Cambrian of Murchison and Geikie, which is so well developed around Loch Maree, and rises into the great dome of the Slioch, or the Spear Head, that guards its waters. The most distinct of the impressions consists of two continuous flat bands side by side, $1\frac{1}{4}$ to $1\frac{1}{2}$ inch broad, and about a quarter of an inch deep, running quite straight across the flat layers of sandstone *in situ*, and perfectly distinct for sixteen feet, disappearing on the west side under the superincumbent rock, and broken only where portions of the sandstone have

been weathered out. In some places a third line runs alongside the two, but this is much less distinct and persistent. The double band resembles nothing more nearly than the hollow impression that would be left by double bars of iron placed closely together and neatly inserted in the rock for clasping some structure on it, if the iron were subsequently removed; or, as you suggest, the marks of a gouge driven by a carpenter across a board. The bands, when looked narrowly into, consist of very fine close hair-like lines, continuous and parallel to their sides, resembling very minute striæ left by glaciation, and look as if caused by some object drawn along the original red sand, before it became the present indurated rock.

"A similar double line runs parallel to this one, about two feet lower down, seven feet long, and a third parallel double line on the other or upper side, three feet long, both of the same breadth as the first. Besides those pointed out by you, which occur on the same flat of sandstone, other lines exist farther down, on the other side of the pool below this rocky flat, on a similar bed of sandstone, part of the same layer—one three feet in length, another six feet, running more or less parallel to those above. Indications of others may also be seen, and, no doubt, several more may be discovered on more careful examination.

"What they are I can scarcely even surmise, having seen nothing of the *same* kind elsewhere. They do suggest the possibility of their being the indentations of the caudal appendage of some huge creature, similar to the hollow tail-lines between the footprints on the sandstone at Tarbatness and along the shores of Morayshire—a suggestion strengthened by the fact of the existence, on both sides of the line, of numerous rounded hollow marks, very like the footprints on these reptiliferous rocks, occurring, as in them, at intervals. But the continuous even breadth and square section of the bands would seem to render this impossible. Then they might be the depressions left on the soft sand by the hinder portions of the shell of some large crustacean—a more likely cause, rendered more probable by the existence of very good ripple marks on the same sandstone, in the same and neighbouring layers. The striæ-like lines of which the grooves consist would seem to point to some moving agent, organic or physical. They may, however, be the casts or impressions of some great land reed or sea fucoid, the hair-lines being the marks of the fine structure of its stem or the parallel veins of its leaves. It would be desirable to have the superincumbent layer of rock carefully removed where the bands in question disappear under the upper rock, which might shed some light on the nature of the strange marks. I was sorry I could not spend more time on their examination."

The impressions occur about 300 or 400 yards above the Victoria Falls, and immediately beside the last of three lesser waterfalls on the west side of the stream.

THE QUANTITIES OF WATER IN GERMAN RIVERS

An attempt has recently been made by Herr Graeve (*Der Civil-Ingenieur*, 1879, p. 591) to determine the amount of water in German rivers and its apportionment in different seasons, a question very important for navigation, and also of much scientific interest. His research comprehends the chief rivers of Germany, excluding the Danube, which begins to be navigable only outside of Germany, and including the Vistula and the Memel. He first calculated, from the mean heights of water, the quantities of water flowing out per second, and he adds a table in which the amount of outflow is shown in relation to the extent of the corresponding river territory. When the amount of outflow per 100 sq. km. of the region of precipitation is calculated the following values are obtained:—(1) the Rhine at Coblentz above the Moselle mouth delivers per 100 sq. km. of land 1·070 cub. m. of water in a second; (2) the Weser at Minden, 0·826 cub. m.; (3) the Elbe at Torgau, 0·579; (4) the Elbe at Barby, 0·554; (5) the Oder at Steinau, 0·460; (6) the Oder below the Warta mouth, 0·413; (7) the Warta near its mouth, 0·344; (8) the Vistula at Montau Spitz, 0·538; (9) the Memel at Tilsit, 0·600.

From these numbers it appears (*a*) that the average outflow of different rivers, from equal portions of their territory, differs much more than is usually thought, for in the Middle Rhine it is about three times, in the Middle Weser two and a half times, and in the Middle Elbe, as also in the Lower Vistula and Memel, more than one and a half times as much as in the Lower Warta. On the whole, it decreases from the Rhine to the Warta, and from the latter increases again to the Memel. (*b*) In one and the same river the quantity from equal portions of land seems as a rule to decrease down stream. (*c*) All calculations of quantity of outflow in streams, based merely on extent of the region of precipitation, must as a rule give incorrect results.

It was important to try and determine the relations of the quantity of outflow to the rainfall of the corresponding regions, and Herr Graeve, doing so by a method which he describes, obtained the following percentage numbers, corresponding to the above series of rivers:—(1) = 38·5 per cent.; (2) = 37 p.c.; (3) = 30 p.c.; (4) = 28·5 p.c.; (5) = 27·2 p.c.; (6) = 21·4 p.c.; (7) = 21 p.c.; (8) = 29 p.c.; (9) = 32·5 p.c.

From this the following conclusions (briefly) are drawn:—

(*a*) The percentage proportion of the amount of outflow to the rainfall differs very considerably in these several rivers, though far less than the amount of outflow from equally large regions of these rivers; hence the differences of the latter can be due only in part to differences in the rainfall.

(*b*) The percentage decreases from the Rhine to the Warta, and increases again from the latter to the Memel. In one and the same river a decrease is perceptible down the stream, at least so far as the phenomena in the Oder and the Elbe are general.

(*c*) Since in a mountainous region a greater part of the atmospheric precipitates is carried off by rivers than in the plain, the steady decrease in the percentage proportion of outflow to rainfall in the direction from the Rhine to the Warta must be primarily attributed to the increasing flatness of the region; so too must the decrease of the percentage down stream. The influence of more or less wood on the land could not be precisely determined.

(*d*) The marked increase of the percentage in the direction from the Warta to the Memel cannot be explained by the orographic conditions of the region of precipitation, because this region in the case of the Memel is not at all hilly, and in that of the Vistula only a little more hilly than that of the Warta, but since the amount of the evaporated part of atmospheric precipitates is considerably influenced by the mean temperature of the region of precipitation, and this in the region of the Vistula and the Memel is lower than in that of the Warta, the increase of percentage in question from the Warta to the Memel must mainly be attributed to climatic conditions.

(*e*) While the percentage in question must be chiefly governed by orographic and climatic conditions, there can be no doubt that other factors also act, *e.g.*, the relative amount of moisture in the air, which influences the degree of evaporation, and in general must decrease from the rainy Rhine region to the dry region of the Warta; further, the amount of plantation, which in the regions of the Vistula and Memel is larger than in those of all other German rivers; lastly, the nature of the ground, allowing more or less passage to the precipitates; the influence of all these factors, however, cannot be proved with the same certainty as the orographic and climatic conditions.

A comparison of the amounts of outflow in different years shows that in individual rivers more important differences occur than are generally supposed, that these differences in rivers of different character and unequal force are very different in amount, and that in the same river they decrease down stream.

With regard to the difference in amount of outflow in the various seasons and months, the following average values were obtained. The amount of outflow in winter (from the beginning of November to the end of April) is to that of summer, at the parts of the stream examined, in the Rhine as 1 : 0·922, in the Weser as 1 : 0·434, in the Elbe as 1 : 0·467, in the Oder as 1 : 0·525, and further down stream as 1 : 0·522, in the Vistula as 1 : 0·486, and in the Memel as 1 : 0·389. A better idea of the regularity of the quantities of outflow is given by the relations of these for the dryest and the wettest month of the year; in the case of the Rhine this ratio is 1 : 1·458, in the Weser 1 : 4, in the Elbe 1 : 5·238, in the Oder 1 : 4·5, and further down 1 : 3·68; in the Vistula 1 : 4·19, and in the Memel 1 : 4·51.

The causes of the difference in the ratio of the largest and least monthly amounts of outflow must chiefly be sought in the presence or absence of collecting basins, as also in the orographic and climatic conditions. In the Rhine all those factors combine which affect the regularity of outflow. It possesses in the Swiss lakes large reservoirs; its river-region comprises mountains of various height, and plains, so that the

melting of the snow must occur at very different times of the year The Memel also possesses reservoirs in its marshes, and its region is perhaps better wooded than that of the other streams of Germany, but the long and hard winters cause an accumulation of large masses of ice and snow which melt suddenly and almost simultaneously in the whole region.

Herr Graeve takes up various other points, which have a practical bearing on navigation, but for these we must refer the reader to his memoir. He remarks in concluding on the desirability of comparing the conditions of outflow of German rivers with corresponding data for other European rivers, though at present the scanty and incomplete character of the data at hand render such inquiry scarcely practicable.

SCIENTIFIC SERIALS

THE *Journal of the Russian Physical and Chemical Society*, vol. xii. fascicules 5 and 6, contain, besides the minutes of meetings of the Society, the following papers :—In fascicule 5 On the dosage of chromium, by M Th. Willm.—On the composition of the hydrate of peroxide of barium, by M. E Schone —On the distribution of naphtha on the peninsula of Apsheron, by M. S Goulichambaroff —On the oxidation of ketones, by M. Goldstein —On the products of oxidation of erythrite, by M S. Przibytek —A necrology of Prof Nicolas Zinin, by MM. Borodin and Boutleroff —On the magnetisation of liquids, by M Ziloff.—On hail, by M. Schwedoff —Notes by M. Latchinoff on specific heat, on a new dynamometer, and on electrical light.—In fascicule 6 : On chlorocamphoric oxide, by M. Latchinoff —On the action of heat on phosphorites, by M Beletzky —On tetrolic acid, by M. Lagermark —On the solidification and evaporation of drops of liquid, by M Sloughinoff —On the dosage of mercury and arsenic in corpses , and an analysis of the artesian wells of Staraya Roussa.

Revue internationale des Sciences biologiques, July, 1880 — J. L. de Lanessan, on the protozoa (a chapter with illustrations from the author's forthcoming "Manuel d'Histoire Naturelle médicale) —A. Hovelacque, on the inferior races of mankind — M. Debierre, man before and on the threshold of history —Proceedings of the Academies of Paris, Belgium, and Amsterdam

August —J L. de Lanessan, the coloration and the colouring-matters in plants.—M. Moniez, on the cysticers of Tænia —M Debierre, man before and on the threshold of history —Proceedings of the Academies of Paris, Belgium, and Amsterdam.

September.—M Vulpian, physiological study of poisons : curare —M. J. L de Lanessan, the saccharomycetes and the fermentations caused by them.—Prof W. H Flower, on the comparative anatomy of man (translated from NATURE).—M R Moniez, on cestoid worms and helminthologists.—Proceedings of the Academy of Paris

SOCIETIES AND ACADEMIES

LONDON

Chemical Society, November 18 —Prof H E Roscoe, president, in the chair.—It was announced that a ballot for the election of Fellows would take place at the next meeting (December 2) —The following papers were read .—Notes on the oxides of manganese, by Spencer Pickering Various samples of oxides were procured and heated to various temperatures, until their weight was constant , in some cases they lost weight, in others they gained, whilst in some the weight remained constant.—On aluminium alcohols, by J H. Gladstone and A Tribe When aluminium foil and iodine are heated with alcohol the latter is decomposed, two new organic aluminic compounds being formed, aluminic iodoethylate $(C_2H_5O)_6I_6Al_2$, and aluminic ethylate $Al_2(C_2H_5O)_6$ The authors have applied this reaction to other alcohols, and have thus prepared aluminic methylate, ethylate, propylate (isopropylate could not be obtained), isobutylate, amylate, cetylate, phenylate, cresylate, and thymolate. —Mr. W H. Perkin then gave an account of the artificial production of indigo by A. Baeyer, and prepared some before the Society. The steps in the process are : toluene C_7H_8O, dichloride of benzyl $C_6H_5CHCl_2$, cinnamic acid $C_9H_8O_2$, orthonitrocinnamic acid $C_9H_7(NO_2)O_2$, orthonitrodibromhydrocinnamic acid $C_9H_7Br_2O_2(NO_2)$, by the action of caustic potash orthonitrophenylpropiolic acid $C_9H_5(NO_2)O_2$ is formed, which on reduction in alkaline solution with grape sugar furnishes indigo $C_{16}H_{10}N_2O_2$.—On the synthetical production of new acids of the pyruvic series, by E. Moritz.—On the old alum well at Harrogate, by R. H. Davis. The author gives an analysis of the mineral constituents in the residue.—On the absorption spectrum of ozone, by W N Hartley —On the probable absorption of the solar rays by atmospheric ozone, by W. N. Hartley. The author has photographed and measured the absorption spectrum of ozone , he suggests that the shortening of the solar spectrum at the violet end is due to the presence of ozone in the atmosphere, also that the blue colour of the sky may be ascribed to the same cause.—On peppermint camphor, by M. Moriya of Tokiô The author has studied carefully the physical characters of this substance , he has also investigated the action of chromic acid, nitric acid, and bromine thereon

Zoological Society, November 16 —Prof Huxley, F.R S., vice-president, in the chair —Mr. W K Parker, F.R S , read a paper on the development of the skull in the Urodele Batrachians Mr. Parker described the skull of the adult Gigantic Salamander (*Sieboldia maxima*), the Siren and the Menopoma, and compared their structure with that of the various stages of the skull of the common newt.—Mr G. E Dobson, C.M Z S., exhibited and made remarks on the head of a partridge (*Perdix cinerea*) with an extraordinary prolongation of the intermaxillary bones —Mr W A. Forbes, F.Z S., made some remarks on the shedding of the horns of the Prong buck (*Antilocapra americana*), as recently observed in the specimen living in the Society's Gardens.—Mr Harting, F Z.S , exhibited a specimen of Bartram's Sandpiper, recently killed in Lincolnshire —Mr Sclater exhibited the skin of the Guinea Fowl, lately described in the Society's *Proceedings* as *Numida Ellioti*. Further investigation had induced him to believe that this bird was the same as *Numida pucherani* of Hartlaub, the inaccurate colouring of the head in Mr Elliot's figure of that species having prevented its identification —Mr G. A. Boulenger read a paper on the Palæarctic and Æthiopian species of *Bufo*, of which he recognised ten species : four in the Palæarctic, five in the Æthiopian region, and one found in both regions —A communication was read from Dr. Otto Finsch, C M Z.S., in which he gave a list of the birds of the Island of Ruk, in the Central Carolines —A second communication from Dr. Finsch contained the descriptions of some new or little-known species of pigeons from the Caroline Islands.—A communication was read from Mr. Edgar A. Smith, containing an account of the shells of the genus *Myodora* of Gray.—A communication was read from Mr Martin Jacoby, in which he gave the descriptions of a collection of Phytophagous Coleoptera made by Mr. Buckley at Eastern Ecuador. The collection contained a good many new and interesting species, of which a great part were not alone inhabitants of Ecuador, but had been found either in Peru or the Amazonian region.—A paper by Messrs F D. Godman and O. Salvin was read, in which they gave the descriptions of some supposed new species of butterflies collected by Mr Andrew Goldie in the interior of the district of Port Moresby, New Guinea.

Physical Society, November 13 —Prof W G Adams in the chair —Mr. Bosanquet, of St John's College Physical Laboratory, Cambridge, read a paper on the nature of the sounds which occur in the beats of consonance. From mistimed octaves and twelfths he found that when the beats of the harmonics are cleared away each beat consists entirely of variations in the intensity of the lower notes. He gave the mathematical theory of these beats, and likewise of the curves given by the harmonograph He also described an ear tube for using in connection with a resonator It is difficult to get definite results with a resonator unless the passage from the latter to the ear is closed to sound The ear tube consists of a copper pipe bent into a sickle shape to gird the face, so that the ends may enter the ears, into which they are screwed, plugging them close The sound is led from the resonator to the middle of the bent pipe by a flexible india-rubber tube, and thence to the ears.—Mr. Brown read a paper on action at a distance. He drew attention to the fact that though Newton disbelieved in action at a distance, he did not pronounce whether the medium was material or immaterial. Mr. Brown showed that the hypothesis of a material medium was encumbered with difficulties, since, among other reasons, direct contact could not explain gravity, projection of small particles from one body to another could not explain attraction, and Lesage's theory of corpuscles (as modified by Mr. Tolver Preston) required an enormous degree of porosity in masses of matter. The nature of magnetism and vibrations was also discussed by the author —Mr J. Macfarlane Gray read a paper on the mechanical nature of the forces called attraction, and gave grounds for attributing them to the pressures of a universal material ether of a gaseous nature The paper was long, and had to be in part left unread. The hypothesis held by Mr. Gray

is remarkably confirmed by numerical results obtained by him.—Prof. Cottrell threw some doubts on Mr. Gray's results on the score that numerical coincidences were not always safe ground for basing theoretical deductions on. Mr. Gray stated that in the parts of the paper which had to be skipped Prof. Cottrell's objections were answered. He also pointed out that Mr. Brown in his criticism of the gasiform ether had not taken into account the important condition that the particles of ether have volume.—Professors Perry and Ayrton read a note on the contact theory of Herr Exner recently brought before the Academy of Sciences of Vienna They showed that Exner's experimental results disagreed with the concordant results of several independent experimenters, namely, Kohlrausch, Hankner, and Ayrton and Perry. They concluded that Herr Exner's experiments were inaccurate. They further argued that Exner's second and later paper, so far from being a disproof of the contact theory of electromotive force as now received, is in reality a proof of it. Dr. Wright stated that he will read a paper on this subject soon; and Prof. Reinhold said that Herr Exner had since corrected some of the results of his early papers on contact electricity.—Prof Minchin of Cooper's Hill Engineering College exhibited a new photo-electric cell. This consists of a vessel of water containing a little acid, carbonate of calcium, and two tinfoil plates. When a beam of lime light was allowed to fall on one of the plates, a powerful current was set up in the cell, as seen by the deflection of a galvanometer connected in circuit with the plates. When a red glass screen intercepted the beam, the effect was very slight Prof. Minchin had begun his experiments with fluorescence, but found "hard" water containing this salt of lime do equally well. The cell possesses this advantage that the current it gives soon decreases in the light When first the light falls on it, the exposed plate is positive, but it soon changes to negative Prof. Minchin had tried the cell in place of a selenium one in the photophone, but with unsatisfactory results.

Anthropological Institute, November 9—Edward B. Tylor, D.C L, F.R.S., president, in the chair.—A paper was read on anthropological colour phenomena in Belgium and elsewhere, by J Beddoe, M.D., F.R.S. Within the last few years the numerical method had been extensively applied to the determination of ethnological colour-types, the Anthropometric Committee of the British Association having set the example. The Continental nations were, however, now far ahead of us. In Germany Prof Virchow had procured the tabulation as to the colour of the eyes and hair of all the school population, with the exception of Hamburg In Switzerland Dr. Guillaume, of Neuchâtel, had obtained school statistics. For Belgium an elaborate monograph had been written on the subject by Prof. Vander Kindere, who, by the aid of the National Geographical Society, had induced the Minister of Public Instruction to include questions on the colour of the children's eyes and hair in the educational census. The results obtained have been of considerable importance, and bring out a remarkable contrast between the Flemish and Walloon provinces of Belgium.—Mr. J. F. Rowbotham read a paper on different stages in the development of the art of music in prehistoric times. Musical instruments, though their varieties may be counted by hundreds, are yet readily reducible under three distinct types, 1. The drum type 2. The pipe type 3. The lyre type. And these three types are representative of three distinct stages of development through which prehistoric music has passed Moreover, the stages occur in the order named. That is to say, the first stage in the development of instrumental music was the drum stage, in which drums, and drums alone, were used by man. The second stage was the pipe stage, in which pipes as well as drums were used. The third stage was the lyre stage, in which stringed instruments were added to the stock. The three stages answer respectively to rhythm, melody, and harmony. And as in the geological history of the globe the chalk is never found below the oolite, nor the oolite below the coal, so in the musical history of mankind is the lyre stage never found to precede the pipe stage, nor the pipe stage to precede the drum stage.—A paper was read on neolithic implements in Russia, by Prince Paul Poutiatine. From the evidence of certain finds on his estate the author came to the conclusion: 1. That the Sclave-Scythians existed there in the stone period. 2 That they possessed instruments resembling those of the Celt-Scythians, and burned their dead. 3 That the old iron period of that neighbourhood was a continuation of the stone period. 4. That they supported themselves partly by hunting. 5. That they understood corn-growing.

Meteorological Society, November 17.—Mr. G. J. Symons, F.R.S, president, in the chair.—The following gentlemen were elected Fellows: G. Corden, E. T. Dowson, F. Hepburn, B.A., C. M. Hepworth, J. Mulvany, M.D., R N., F. H. G. Newton, Capt. M. Parry, E. P. Phillips, and H. L Roth.—The papers read were: Table of relative humidity, by Edward E. Dymond, F M S.—Rainfall in South Africa, by John G Gamble, M.A, M. Inst. C.E., F.M.S. The author gives the monthly totals of rainfall from 103 stations for the thirteen months, December 1878 to December 1879, and also the monthly means from all stations in South Africa from which a record of five years or upwards could be obtained. It is shown that the Cape Peninsula, the South-West and the West Coast, have winter rains with a dry summer, characteristics of what is called the subtropical region, the rains coming with the north-west wind or anti-trade, while Natal, Aliwal north, and in a less degree Queenstown, have the tropical features of a wet summer and dry winter. On the South Coast the rainfall appears to be more equally distributed throughout the year, though there seems to be an October maximum at Port Elizabeth and Uitenhage. In the Central and Northern Karroo the maximum of the very scanty rainfall occurs in February and March. These rains generally fall in thunderstorms; each storm seems to come from a westerly direction, but it is a more or less well-ascertained fact that these rains do not fall up country until the south-easters have set in on the South and South-West Coasts In the south-east of the colony the transition towards tropical features may be noticed, both Grahamstown and King Williamstown showing a winter minimum in June—On the meteorology of Mackay, Queensland, by Henry L Roth—Thermometrical observations on board ship, by Capt. W F. Caborne, F.M.S.

VIENNA

Imperial Academy of Sciences, November 18.—Contributions to general nerve and muscle physiology, by Dr. Biedermann—On rhythmic contractions of striped muscles, produced by chemical stimulation, by the same.—On some platino-cyanide compounds, by Herr Scholz.—On resorcin colouring matters, by Drs. Wesselskyund and Benedikt—On the formation of carboxylnatron acid from Brenz, catechin, and the constitutional formula of benzol, by Prof. v. Barth.—Note on mononitropyrogallol, by the same—The distribution of rainfall over Austria in the period August 11-15, 1880, and its relation to distribution of air-pressure, by Herr Hann.

POLITICAL ECONOMY

Guide to the Study of Political Economy. By Dr Luigi Cossa, Professor of Political Economy in the University of Pavia. Translated from the second Italian edition. With a Preface by W. Stanley Jevons, F R S. (London: Macmillan and Co, 1880)

THE translator of Prof. Cossa's "Guide" has conferred a great boon upon the English student of political economy. The present condition of economic science generally, and especially in this country, cannot be regarded as satisfactory. The doctrines once regarded as firmly established, and the limits of discussion apparently viewed as fixed by the nature of the facts, have been subjected to criticism from the most varied grounds, and the process of disintegration, not yet completed, has not led to any general agreement with respect to the scope and principles of the science. The system of political economy, which with some justice we designate as the English, has been revised or attacked on two grounds mainly. In the first place, the fundamental notions upon which it proceeded have been criticised as too narrow and limited, as referring solely to one economic condition and as leading to results of an abstract and isolated character The "Economic Studies" of the late Mr. Bagehot represent fairly this phase of opinion, while the excellent little compendium by Prof. and Mrs Marshall, the "Economics of Industry," is a specimen of the mode in which the older theorems require to be restated in the light of more general principles. In the second place, the great advance in what we may call social science, and the application of the historic method to the study of the various orders of social facts, have led, on the part of many modern writers, to an almost total rejection of the whole system of doctrines grouped together under the title of Political Economy The fundamental principles, the methods of reasoning from them, and the conclusions arrived at, have all been questioned, while a perfectly chaotic state of opinion appears to exist regarding the nature and method of that which is to take the place of the formerly accepted doctrine.

The present work supplies most timely aid in the discussion of these complicated problems. The first part (pp 1–84), which treats in a thoughtful and judicious manner the province of political economy, its method, and its bearing upon social facts generally, brings into due prominence the immense extent and variety of the inquiries which, in an unsystematic fashion, have come to be included in one body of doctrine, and fairly warrants the conclusion that in future we must regard political economy as a complex of different sciences, with distinct aims and requiring distinct methods of treatment. The second part (pp 85-227), containing a brief sketch of the history of the science, which we may without hesitation pronounce as unrivalled of its kind, leads by another path to the same result. The English student will learn from this history of the development of the science, more especially from the admirable account of recent German and Italian works, the nature of the various general principles which have been accepted as furnishing the foundation of economics and its allied branches, and will be enabled to discover in what respects mainly the peculiar doctrines of the older system require revision and amendment.

Prof. Cossa would doubtless be the first to admit that the brief treatment here given of so complex a problem as the determination of the province and logical character of political economy cannot be expected to furnish a final solution. His remarks on the essential nature of pure or theoretical political economy, which he regards as the science of the *social* laws of wealth, are at least instructive and helpful, while the sections on the relation of economics to the various branches of legislative science leave little to be desired At the same time it may be doubted whether there is really any place for the art of political economy here alluded to, and it may be questioned whether the mode the author adopts for separating economics from technology on the one hand, and from economic legislation on the other, is satisfactory in itself, or so clear as what we find, *e g*, in Hermann and Wagner The chapter on Method in Political Economy contains little more than a judicious reproduction of Cairnes' well-known essay, and the remarks on the historical method, though acute and sensible, do not seem to us to go to the root of the matter

The historical sketch, the main feature of the work, deserves every praise that can be given for breadth and exactitude of knowledge, for fairness and acuteness of criticism Particularly valuable are the sections on the Political Economy of the Greeks and Romans, and on the Physiocratic school. One recognises with satisfaction the cordial appreciation extended by the author to certain great works of modern Continental economists which are scarcely known, even by name, in this country, but which must be pronounced absolutely indispensable to the student. Such *e g*. are v. Hermann's "Staatswirthschaftliche Untersuchungen," the first section of which is certainly the best treatment of the fundamental notions of pure economics, v. Mangoldt's "Volkswirthschaftslehre," Knies' "Geld und Credit," Courcelle-Seneuil's "Traité," and Cherbuliez' "Précis." As text-books of the subject, v Mangoldt's "Grundriss" and Cherbuliez' "Précis" are unsurpassed.

Naturally one cannot always assent to the critical opinions expressed on detached doctrines or authors. Thus it seems to us that the author ought not to have included Codillac without further mention as a follower of Quesnay; that his estimate of the merits of Storch's "Cours" is much too low, that he is hardly fair to von Thunen's acute speculations on interest and wages, and that he is quite mistaken regarding the nature of v Mangoldt's theory of profit What Prof. Cossa, in this connection, stigmatises as "an equivocation" (p. 200) is in fact a misunderstanding of his own

In a brief sketch covering so wide a literature as that of political economy, absolute completeness is not to be expected, and probably the author has good reasons for omitting various names which occur to one as having a place in the history of the science. Still one is surprised to find a studious omission of the whole school of economical writers to which the vague term *socialist* has been applied. Proudhon, we think, is mentioned once; Fourier, St. Simon, and Karl Marx are not mentioned at all. So

too, American writers are dismissed without notice, save a passing allusion to F A. Walker. Carey's theories are occasionally referred to in connection with other names, but no specific account is given of them, nor are other American authors, orthodox or heterodox, better treated. Even a general history ought not, one would think, to have omitted notice of such writers as Lord Lauderdale (whose treatment of Demand and of the Functions of Capital has not received the attention it deserves), R. Jones (whose essay on the Early English Economists might also have been noted in its proper place), Jacob, Stirling (the translator of Bastiat and author of an excellent but well-nigh forgotten work, "Philosophy of Commerce"), Bernhardi (the author of a remarkable treatise on Large and Small Landed Properties), Hubner, H. Thornton, Baumstark, Skarbek, Cieskowski, Saint-Chamans, Esmenard de Mazet, Louis Say, Schon, Canard, and Cazeaux. Dureau de la Malle's work might have been noted in connection with the political economy of the Romans, and De Tracy's name should not have passed without reference to his commentary on Montesquieu.

The translation appears to us generally excellent, and the translator, who is evidently well acquainted with the subject, deserves much credit for the clear and concise English into which she has rendered Prof. Cossa's work

OUR BOOK SHELF

Avis préliminaire d'une nouvelle Classification de la Famille des Dytiscidæ Par D Sharp. (Extrait des *Comptes rendus* de la Société Entomologique de Belgique, Séance du 4 septembre, 1880)

DR. SHARP is well known to have been long occupied on a work on the water-beetles of the world (at any rate on those of this particular family) The author announces it as ready for the press, and has forwarded to the Belgian Entomological Society a sketch of his ideas of the limits of the family and its classification, from which we learn that about 80 genera are recognised One of the most important characters, as separating true *Dytiscidæ* from *Carabidæ* and from all other *Coleoptera*, appears to consist of the condition of the metathoracic episternum in connection with the intermediate cotyloid cavities The family as a whole is divided into two great divisions, termed "*fragmentati*" and "*complicati*," the latter being headed by the anomalous genus *Amphizoa*, the position assigned to which will perhaps not find universal favour No one can doubt that the book, when it appears, will mark an era in this department of entomology It is a great pity therefore that Dr Sharp should throw himself open to the shafts of ridicule in his choice of terms wherewith to designate some of his new genera We need only allude here to such terms as *Huxelhydrus* (presumably a misprint for *Huxleyhydrus*), *Darwinhydrus*, and *Tyndallhydrus* ! ! ! We all honour the names that form the prefixes, and fail to realise the watery connection suggested.

Aid to the Identification of Insects Edited by Charles Owen Waterhouse Lithographs by Edwin Wilson. Small 4to, Part I. (London. E W. Janson, 35, Little Russell Street, W.C.)

MR. WATERHOUSE, whose duties in the zoological department of the British Museum have probably continually caused him to feel the want of some such work as that which he now commences under the above title, has conceived the idea of issuing, at intervals of a month or six weeks, a series of hand-coloured drawings of insects of all orders not previously figured. Every working naturalist knows that a good pictorial representation conveys a more accurate and ready perception of a species than the most elaborate verbal description; and we can imagine no more ready way of widely disseminating a knowledge of the arcana of science than this. Each part is to contain eight or nine plates, each representing a single species, with its generic and specific names, the name of its describer, and a reference to its locality and place of description The plates can be classified on the completion of a volume (twelve parts), when a title-page and index will be issued.

The first part, just issued, contains some well-executed figures of *Coleoptera*, *Hemiptera*, and *Lepidoptera*. The whole idea is unconsciously a repetition of Prof. McCoy's "Prodromus of the Zoology of Victoria," but with no Government money to back it up.

LETTERS TO THE EDITOR

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.]

The Editor urgently requests correspondents to keep their letters as short as possible The pressure on his space is so great that it is impossible otherwise to ensure the appearance even of communications containing interesting and novel facts.]

Geological Climates

I HAVE read with much interest Mr Starkie Gardner's letter in NATURE, vol. xxiii p 53.

It is not necessary for me to discuss the question whether I am right in requiring an increase of 20° F. mean annual temperature at Bournemouth in Eocene times, or whether he is right in demanding an increase of only 14° F to 15°, for I am able to show that the one increase is as *impossible* as the other, on the principles held by Lyell and his followers.

Mr Starkie Gardner's ideas on the subject of oceanic circulation and its effects upon climate are expressed in the following words.—

"The general cooling effect of incessant oceanic circulation between the North Pole and the Tropics is, I think, scarcely taken into sufficient account, and although it may be contended that conversely the northerly flow of the Gulf Stream mitigates climate, I think that its action in Europe is chiefly in fending off the ice-laden currents from our coasts," &c, &c.

This statement, to my mind, involves so complete a misapprehension not only of the physical causes of oceanic circulation, but also of the whole problem of geological climate, that I shall ask your permission to lay down a few elementary propositions on the subject, which are capable of demonstration

1 The Gulf Stream of the North Atlantic, so far from acting the part of a policeman in "fending off" imaginary cold water streams from the Polar regions, is the *cause of their existence.* If there were no Gulf Stream there could be no Labrador current of cold water running south The same statement is true of the Kuro Siwo of the North Pacific, of the Brazilian current of the South Atlantic, and of the Mozambique curren of the Indian Ocean.

2 If the globe were covered with water, or in the condition of an archipelago pretty uniformly distributed, there would be no exchange of currents between the Tropics and the Poles, and consequently no effect upon climate Within the Tropics there would be a broad, slow current of warm water moving from east to west, and producing no effect upon climate. In the temperate zones there would be in the northern hemisphere a feeble interchange of south-westerly and north-easterly currents, and in the southern hemisphere a similar interchange of north-westerly and south-easterly currents, both incapable of affecting climate to any sensible degree.

3. If a north and south barrier be constructed to the westward of a locality like the West of Europe; such a barrier as North and South America affords, a gulf stream is, at once, formed, and a corresponding Labrador current running in the opposite direction.[1] The effect of the Gulf Stream is to raise the temperature of the West of Europe to its *maximum*, and the effect of the Labrador current is to depress the temperature of the east coast of North America to its *minimum*.

4. It is *impossible* to suggest any rearrangement of land and water which shall sensibly *raise the temperature of the West of*

[1] The earth's rotation compels the Gulf Stream to impinge on the west coast of Europe, and the Polar current on the east coast of North America.

Europe, or sensibly *depress the temperature of the east of North America.*

Mr. Gardner makes the following hypothetical redistribution of land and water :—

"Supposing, as all evidence tends to prove,[1] that Northern Europe and America were connected by continuous land in Eocene time, would not the mere fact of shutting off the Arctic seas cause a general and perhaps sufficient rise of temperature ?"

My answer to this is that such an arrangement of land and water in the North Atlantic would raise considerably the present *minimum* temperature of the east coast of North America, but would produce little or no effect in raising the already *maximum* temperature of West Europe, which already receives the full benefit of the Gulf Stream, and suffers none of the injuries of the Labrador current.

It seems to me not possible to raise the mean annual temperature of Bournemouth 15° F. or 20° F. without supposing an *increased Gulf Stream*, in other words, an *an increased sun-heat*, which is contrary to the ideas of Lyell and his followers.

I must again ask Mr. Duncan to name the *species* of bamboo that flourishes so luxuriantly at Cooper's Hill under the disadvantageous conditions he has so well described.

If he decline to do so I have no other remedy than to go to the Indian Engineering College on my next visit to London, and inspect and report on the bamboo myself.

Trin. Coll. Dub., November 23 SAML. HAUGHTON

[1] I entirely deny this, but will not now turn aside from my present purpose to discuss it.

"Sulphuric Acid and Alkali"

MR. MACTEAR informs me that the statements contained in my review of Prof. Lunge's second volume, which appeared in your columns last week, require amendment, and I beg, in justice to Mr. Mactear, to make the following remarks :—

1. It appears that the direct object of Mr. Mactear's process is to reduce the amount of limestone to the least possible amount. Hence the words "in excess of that usually worked" are to be omitted in the sentence referring to this subject.

2. With regard to the statement that many thousands of pounds have been gained in a single works by the adoption of Mr. Mactear's process, that gentleman has placed in my hands the proof that this fact is correct.

There remains however no doubt that, in the Lancashire district at least, the liming process is not now so generally adopted as Dr. Lunge implies; but this may be explained by the fact that Mactear's process greatly reduces the quantity of caustic soda, and this does not suit the Lancashire plan of working. H. E. ROSCOE

A General Theorem in Kinematics

PROF. MINCHIN has been anticipated in his discovery of the theorem on uniplanar motion given in NATURE, vol. xxiii. p. 62. It was published some six years ago by Prof. W. Schell of the Polytechnikum, Carlsruhe, in the *Zeitschrift fur Mathematik und Physik*, xix. 3. The paper containing it is entitled "Ueber den Beschleunigungzustand des ebenen unveranderlichen, in der Ebene beweglichen Systems," and commences at p. 185. The two parts of the theorem will be found in leaded type at pp. 190 and 192. The paper (which is an admirable specimen of clear writing) is purely kinematical, and treats only of motion *in plano*. The dynamical consequences pointed out by Prof. Minchin are accordingly not to be found in it, nor the analogous theorem for the general motion of a rigid body obtained by Prof. Wolstenholme. The following quaternion proof of the latter theorem may interest some of your readers.

The velocity ρ of the particle at vector distance ρ from a fixed origin is—

$$\dot{\rho} = \alpha + V\beta\rho,$$

α being the velocity at the origin, and β the angular velocity.

The acceleration is therefore—

$$\ddot{\rho} = \dot{\alpha} + V\dot{\beta}\rho + V\beta(\alpha + V\beta\rho),$$

and will be zero for one definite value of ρ.

Taking the point of no acceleration for origin, the constant terms in the expression for the acceleration must vanish, and the expression will be reduced to—

$$\ddot{\rho} = V\dot{\beta}\rho + V\beta V\beta\rho,$$

which is identical with Prof. Wolstenholme's result.

Malone Road, Belfast, November 22 J. D. EVERETT

Phosphorescent Centipedes

ON September 28 last I was walking in my garden here at eight o'clock in the evening with a friend, when we were simultaneously attracted by a bright light about twenty paces in front of us. The light was so bright that in the distance it looked like moonlight through the trees; and had the moon been shining we should probably not again have thought about the light until we came upon it. But it was a dark night, though warm and even sultry, and still. The light was so bright that, taking a letter out of my pocket, I could read it. It resembled an electric light, and proceeded from the bodies of two centipedes and their two trails. The centipedes were about four inches apart. The light illumined the entire body of the animal, and seemed to increase its diameter three times. It flashed along both sides of the creature in sections, there being about six sections from head to tail, between which the light played. The light behaved precisely like the electric light, moving as it were perpetually in two streams, one on each side, and yet lighting up the whole body. In the trail there was no movement, but light only. The trail extended 1½ foot from each centipede over the grass and the gravel-walk, and it had the appearance of illuminated mucus.

Having observed these creatures for several minutes, I picked one of them up and lodged it in a box which had been procured from the house, for further observation. On touching the centipede the light in both animals, as well as in both trails, was instantly extinguished. Later in the evening we found another centipede, and this also emitted light in the same manner, both from body and trail as I have described. My gardener then informed me that he had observed these creatures during the previous three or four evenings, both in the garden and in the stableyard.

On the following day I took the centipede to Prof. Flower, who, with the assistance of the authorities of the British Museum, has identified the species as *Geophilus subterraneus*.

The published descriptions of the luminous properties of the British centipedes differ considerably from what I observed in this instance.

The best, so far as I know, is given in Shaw's "General Zoology," vol. vi. After describing the animal, it proceeds thus. "It is possessed of a high degree of phosphoric splendour, which, however, seems to be only excited when the animal is pressed or suddenly disturbed, when it diffuses a beautiful smaragdine light, so powerful as not to be obliterated by the light of two candles on the same table."

I may observe that I was never able to induce my centipede to shine whilst in captivity. It may also be worthy of note that the atmosphere was exceptionally dry and the barometer remarkably high at the time of the observation.

B. E. BRODHURST

Grange Court, Chigwell, November 22

The Yang-tse, the Yellow River, and the Pei-ho.

ALTHOUGH the conclusions at which Dr. Woeikof has arrived (NATURE, vol. xxiii. p. 9) with regard to my estimations of the discharge of water and sediment of the Yang-tse and Pei-ho may militate against their being accepted as generally typical of these two rivers, I would urge that another series of observations would be of more service in either correcting or in corroborating my estimations.

In the case of the Yang-tse it will have been seen that, according to the estimate of Capt. Blakiston at I-chang and of my own at Hankow—500,000 and 650,000 cubic feet of water per second respectively,—this river increases its discharge by 150,000 cubic feet in the 360 miles that intervene between these two places of observation. In this portion of its course the Yang-tse not only receives the waters of the Han, but is also the recipient of those of the Tung-ting Lake, and the increase it receives from these two important tributaries—an amount exceeding the water-discharge of the Nile[1]—is not such as would support the conclusion that my estimate for the Yang-tse at Hankow is under the usual average.

My observations on the Pei-ho, referring as they do to only a portion of the year, are more open to correction, and a series of observations throughout the entire twelve months are certainly to be preferred.

In conclusion I may state that, although my various estimations are open to criticism, my object will have been gained if, by inviting further inquiry into the hydrological features of the great river system of China, an accurate knowledge of them is obtained. H. B. GUPPY

[1] 130,000 cubic feet per second.

Aurora observed at Ovoca, Co. Wicklow, November 3.—Observations from 5 30 p.m. to Midnight

AT 5.30 p.m. yellow lights tinged with red were coming up all round the horizon; these at intervals formed indistinct columns to the south-west and north west At 6.30 there were faint reddish lights forming fans at different points, these were succeeded by red and orange lights that rose forming glows, columns, and pencils, while at 7 30 a bright silver-white arch appeared to the north—the horns from this arch were pencils of white, which seemed to cross the arch, they were very numerous, appearing and disappearing nearly instantaneously, from about four to seven appeared at one time. Some of them were very long, shooting up to the zenith. After the arch had dissolved away, brilliant narrow, well-defined, thin columns of silver light shot up, the most marked coming up to the north-west at 7 40, this darted up suddenly, and moved gradually southward, and when about due west, close to the church tower, it disappeared at 7 45

These silver lights solely occurred between the west and north-east, while all round the horizon red and orange lights were rising; these sometimes congregated at the zenith in a mass. At 7.50 two brilliant silver pencils rose to the north-north-east, but disappeared nearly instantaneously.

From 8 p m to 8 50 there were orange and red glows of light sometimes in indistinct columns; but at the latter hour there appeared to the north west a vivid display of silver light that lasted about five minutes, this was succeeded by a deep orange cloud that travelled up to the zenith From 9 to 10 30 there was an orange to red glow round the horizon, while at intervals from the north-west rose pencils of silver light, five very brilliant ones rising at 10.30 They were succeeded by a bright silver glow over the whole of the western heaven, across which at intervals passed glows of red and orange light; columns also rose, while at times horizontal streaks of brilliant silver lights appeared and disappeared in a flash At 11 there was an orange glow round the horizon, this, with spurts of light coming up between the south west and north-east, were all that was observed up to midnight.

G H KINAHAN

MR. SPENCER AND PROF. TAIT

WHEN, in NATURE for July 17th, 1879, while reviewing Sir Edmund Beckett's book, Prof. Tait lugged in Mr. Kirkman's travesty of the definition of Evolution, most readers probably failed to see why he made this not very relevant quotation But those who remembered a controversy which occurred some years previously, possibly divined the feeling which prompted him thus to go out of his way

At the time I said nothing, but having recently had to prepare a new edition of "First Principles," and thinking it well to take some notice of books, and parts of books, that have been written in refutation of that work, I decided to deal also with Mr. Kirkman's implied criticism, in which Prof. Tait so heartily concurred, and by way of gauging Prof Tait's judgment on this matter, I thought it not amiss to give some samples of his judgment on matters falling within his own department To make it accessible to those possessing previous editions of "First Principles," the Appendix containing these replies to critics was published as a pamphlet

In the inaugural lecture of this session, recently given to his students, part of which is published in the last number of NATURE, Prof. Tait first of all recalls a passage from the preceding controversy. From this he quotes, or rather describes, a clause which, standing by itself, appears sufficiently absurd; and he marks the absurdity by a double note of admiration. Whether when taken with its context it is absurd, the reader will be able to judge on reading the passage to which it belongs

In disproof of certain conclusions of mine, there had been quoted against me the *dictum* of Prof. Tait concerning the laws of motion, which is that—"as the properties of matter might have been such as to render a totally different set of laws axiomatic, these laws must be considered as resting on convictions drawn from observation and experiment and not on intuitive perception." Not urging minor objections to this *dictum*, I went on to say:—"It will suffice if I examine the nature of this proposition that 'the properties of matter *might have been*' other than they are Does it express an experimentally-ascertained truth? If so, I invite Prof. Tait to describe the experiments? Is it an intuition? If so, then along with doubt of an intuitive belief concerning things *as they are*, there goes confidence in an intuitive belief concerning things *as they are not*. Is it an hypothesis? If so, the implication is that a cognition of which the negation is inconceivable (for an axiom is such) may be discredited by inference from that which is not a cognition at all, but simply a supposition . I shall take it as unquestionable that nothing concluded can have a warrant higher than that from which it is concluded, though it may have a lower Now the elements of the proposition before us are these —*As* 'the properties of matter might have been such as to render a totally different set of laws axiomatic' [*therefore*] 'these laws [now in force] must be considered as resting . . . not on intuitive perception ' that is, the intuitions in which these laws are recognised, must not be held authoritative. Here the cognition posited as premiss, is that the properties of matter might have been other than they are, and the conclusion is that our intuitions relative to existing properties are uncertain Hence, if this conclusion is valid, it is valid because the cognition or intuition respecting what might have been, is more trustworthy than the cognition or intuition respecting what is!"

From which it is manifest that, when asking (of course ironically) whether this alleged truth was an experimentally-ascertained one, my purpose was partly to ennumerate and test all imaginable suppositions respecting the nature of Prof Tait's proposition, and partly to show that he had affirmed something concerning the properties of matter which cannot be experimentally verified, and therefore which, by his own showing, he has no right to affirm

The first example which, in my recent replies to criticisms, I have given of Prof Tait's way of thinking, is disclosed by a comparison of his views concerning our knowledge of the universe as visible to us, and our knowledge of an alleged invisible universe This comparison shows that —

"He thinks that while no validity can be claimed for our judgments respecting perceived forces, save as experimentally justified, some validity can be claimed for our judgments respecting unperceived forces, where no experimental justification is possible"

Part of Prof. Tait's answer is that "the theory there developed [in the "Unseen Universe"] was not put forward as probable, its purpose was attained when it was shown to be conceivable." To which I rejoin that whereas Prof Tait said he found in this theory a support for certain theological beliefs, he now confesses that he found none, for if no probability is alleged, no support can be derived. The other part of his answer concerns the main issue. After pointing out that the argument of this work, "carried on in pursuance of physical laws established by converse with the universe we know, extends them to the universe we do not know," I had urged that if we have "no warrant for asserting a physical axiom save as a generalisation of results of experiments—if, consequently, where no observation or experiment is possible, reasoning after physical methods can have no place; then there can be no basis for any conclusion respecting the physical relations of the seen and the unseen universes," "since, by the definition of it, one term of the relation is absent." Prof. Tait's explanation is extremely startling When following the discussion in the "Unseen Universe," throughout which the law of the Conservation of Energy and the Principle of Continuity are extended from the tangible and visible matter and motion around us to an

unknown form of existence with which they are supposed to be connected, readers little thought that Prof Tait meant by this unknown form of existence his own mind. Yet this is all that he now names as the missing term of the relation between the seen universe and the unseen universe.

The second sample which I gave of Prof Tait's views on matters pertaining to his own subject, concerned the nature of inertia, which he describes by implication as a positive force Here I quoted Prof. Clerk Maxwell. To repeat his criticism in full would cause me to trespass on the pages of NATURE even more unduly than I must do. If, however, any reader turns to NATURE, July 3rd, 1879, and reads the passage in question, he will be able to judge whether it is, or is not, a joke, and if a joke, at whose expense. Meanwhile, the essential question remains. Prof. Tait says that matter has "an innate power of resisting external influences." I, contrariwise, say that the assertion of such a power is at variance with established physical principles.

One further illustration of Prof. Tait's way of thinking was added. Quoting from a lecture given by him at Glasgow, for the purpose of dispelling "the widespread ignorance as to some of the most important elementary principles of physics," I compared two different definitions of force it contained. In a passage from Newton, emphatically approved by Prof Tait, force is implied to be that which changes the state of a body, or, in modern language, does work upon it Later on in the lecture, Prof. Tait says—"force is the rate at which an agent does work per unit of length." I contended that these definitions are irreconcilable with one another, and I do not see that Prof. Tait has done anything to reconcile them True, he has given us some mathematics, by which he considers the reconciliation to be effected, and, possibly, some readers, awed by his equations, and forgetting that in symbolic operations, carried on no matter how rigourously, the worth of what comes out depends wholly on what is put in, will suppose that Prof. Tait must be right. If, however, his mathematics prove that while force is an agent which does work, it is also the rate at which an agent does work, then I say—so much the worse for his mathematics

From these several tests of Prof. Tait's judgment, in respect to which I fail to see that he has disposed of my allegations, I pass now to his implied judgment on the formula, or definition, of Evolution And here I have first to ask him some questions. He says that because he has used the word "definition" instead of "formula," he has incurred my "sore displeasure and grave censure." In what place have I expressed or implied displeasure or censure in relation to this substitution of terms? Alleging that I have an obvious motive for calling it a "formula," he says I am "indignant at its being called a *definition*." I wish to see the words in which I have expressed my indignation; and shall be glad if Prof Tait will quote them. He says—"It seems I should have called him the *discoverer of the formula!*" instead of "the inventor of the definition." Will he oblige me by pointing out where I have used either the one phrase or the other? These assertions of Prof. Tait are to me utterly incomprehensible I have nowhere either said or implied any of the things which he here specifies. So far am I from consciously preferring one of these words to the other, that, until I read this passage in Prof. Tait's lecture, I did not even know that I was in the habit of saying "formula" rather than "definition." The whole of these statements are fictions, pure and absolute.

My intentional use of the one word rather than the other, is alleged by him *à propos* of an incidental comparison I have made. To a critic who had said that the formula or definition of Evolution "seems at best rather the blank form for a universe than anything corresponding to the actual world about us," I had replied that it might similarly be "remarked that the formula—'bodies attract one another directly as their masses and inversely as the squares of their distances,' was at best but a blank form for solar systems and sidereal clusters." Whereupon Prof. Tait assumes that I put the "Formula of Evolution alongside of the Law of Gravitation," in respect to the definiteness of the previsions they severally enable us to make; and he proceeds to twit me with inability to predict what will be the condition of Europe four years hence, as astronomers "predict the positions of known celestial bodies four years beforehand." Here we have another example of Prof. Tait's peculiarity of thought. Because two abstract generalisations are compared as both being utterly unlike the groups of concrete facts interpreted by them, *therefore* they are compared in respect to their other characters.

But now I am not unwilling to deal with the contrast Prof Tait draws, and am prepared to show that when the conditions are analogous, the contrast disappears. It seems strange that I should have to point out to a scientific man in his position, that an alleged law may be perfectly true, and that yet, where the elements of a problem to be dealt with under it are numerous, no specific deduction can be drawn Does not Prof Tait from time to time teach his students that in proportion as the number of factors concerned in the production of any phenomenon becomes great, and also in proportion as those factors admit of less exact measurement, any prediction made concerning the phenomenon becomes less definite, and that where the factors are multitudinous and not measurable, nothing but some general result can be foreseen, and often not even that? Prof. Tait ignores the fact that the positions of planets and satellites admit of definite prevision, only because the forces which appreciably affect them are few, and he ignores the fact that where further such forces, not easily measured, come into play, the previsions are imperfect and often wholly wrong, as in the case of comets; and he ignores the fact that where the number of bodies affecting one another by mutual gravitation is great, no definite prevision of their positions is possible. If Prof. Tait were living in one of the globular star-clusters, does he think that after observations duly taken, calculations based on the law of gravitation would enable him to predict the positions of the component stars four years hence? By an intelligence immeasurably transcending the human, with a mathematics to match, such prevision would doubtless be possible, but considered from the human standpoint, the law of gravitation, even when uncomplicated by other laws, can yield under such conditions only general and not special results. And if Prof. Tait will deign to look into "First Principles," which he apparently prides himself on not having done, he will there find a sufficient number of illustrations showing that not only other orders of changes, but even social changes, are predictable in respect to their general, if not in respect to their special, characters

There remains only to notice the opinion which Prof Tait seems still to hold, that the verbal transformation which Mr Kirkman has made in the formula or definition of Evolution, suffices to show its hollowness. Here I may be excused for repeating what I have already said elsewhere, namely, that "We may conveniently observe the nature of Mr. Kirkman's belief, by listening to an imaginary addition to that address before the Literary and Philosophical Society of Liverpool, in which he first set forth the leading ideas of his volume, and we may fitly, in this imaginary addition, adopt the manner in which he delights

"Observe, gentlemen," we may suppose him saying, "I have here the yolk of an egg The evolutionists, using their jargon, say that one of its characters is 'homogeneity'; and if you do not examine your thoughts, perhaps you may think that the word conveys some idea. But now if I translate it into plain English, and say that

one of the characters of this yolk is 'all-alikeness,' you at once perceive how nonsensical is their statement. You see that the substance of the yolk is not all-alike, and that therefore all-alikeness cannot be one of its attributes Similarly with the other pretentious term 'heterogeneity,' which, according to them, describes the state things are brought to by what they call evolution It is mere empty sound, as is manifest if I do but transform it, as I did the other, and say instead 'not-all-alikeness' For on showing you this chick into which the yolk of the egg turns, you will see that 'not-all-alikeness' is a character which cannot be claimed for it. How can any one say that the parts of the chick are not-all-alike? Again, in their blatant language we are told that evolution is carried on by continuous 'differentiations'; and they would have us believe that this word expresses some fact. But if we put instead of it 'somethingelseifications' the delusion they try to practise on us becomes clear How can they say that while the parts have been forming themselves the heart has been becoming something else than the stomach, and the leg something else than the wing, and the head something else than the tail? The like manifestly happens when for 'integrations' we read 'sticktogetherations' what sense the term might seem to have, becomes obvious nonsense when the substituted word is used For nobody dares assert that the parts of the chick stick together any more than do the parts of the yolk I need hardly show you that now when I take a portion of the yolk between my fingers and pull, and now when I take any part of the chick, as the leg, and pull, the first resists just as much as the last—the last does not stick together any more than the first, so that there has been no progress in 'sticktogetherations.' And thus, gentlemen, you perceive that these big words which, to the disgrace of the Royal Society, appear even in papers published by it, are mere empty bladders which these would-be philosophers use to buoy up their ridiculous doctrines"

But though it is here, I think, made apparent enough that even when disguised in Mr Kirkman's grotesque words, the definition of Evolution continues truly to express the facts, Prof Tait shows no sign of changing his original opinion that Mr Kirkman has made "an exquisite translation" of the definition Nay, so charmed does he appear to be with Mr Kirkman's feats of this nature, that he gives us another of them One of two conclusions must be drawn. Prof Tait either thinks that fallacies are disclosed by the aid of these cacophonous long words, or else the clatter of curious syllabic compounds greatly excites his sense of humour In the last case we may infer that had he been one of that "Twelfth Night" party in which the Clown exclaims—"I did impeticos thy gratillity," he would have joined in Sir Andrew Aguecheek's applause HERBERT SPENCER

NOTES ON THE GEOLOGY OF EAST-CENTRAL AFRICA

THOUGH many travellers have now penetrated almost every part of Central Africa, and described the main geographical features, yet their accounts have been singularly barren in any reliable geological details. The Geographical Society, in its late expedition to the lake region, sought to remedy this want, and I, as a student of that science, had the honour of being selected as geologist and assistant to Mr. Keith Johnston, the leader of the expedition.

After the lamentable death of Mr. Johnston, almost at the commencement of our journey, the entire work of the expedition fell into my inexperienced hands, and to perform that work conscientiously precluded all hope of anything but the most superficial geological research. The difficulties in the way were, as in all tropical countries, much increased by the luxuriance of the vegetation, which seldom leaves a rock uncovered and exposed to view. Notwithstanding these obstacles to geological investigation, however, glimpses of the internal structure of the country traversed were here and there obtained, which I think may fairly be considered as shadowing forth the main general features of the geology of the Great Lake Region

Let me briefly point these out in the order of their occurrence along our route to Nyassa and Tanganyika. The comparatively unbroken stretch of low-lying country which so markedly borders the East Coast of Africa is formed of two, if not three, raised beaches, elevated in recent times above the sea. They consist chiefly of brick-red sands and clays overlying coral rock. The former have been derived by denudation from the coast ranges, which, consisting of hornblende rocks and others containing a large amount of iron, easily account for the deep-red colour characterising these deposits. The sands are of value as containing the gum copal, of which our best varnishes are made As the tree from which this gum has been derived is now almost extinct, it would seem that a considerable lapse of time has occurred since these deposits have been formed; but geologically they must be recent, as among the many insects that have been found imbedded in the copal none, as far as I am aware, are extinct The Msandarusi, or gum copal tree, has evidently been restricted to the sea-coast, as neither it nor the gum has ever been found as yet in the interior.

In passing from these sands and clays we step over an immense gap in the geological record, of which no trace remains, as the rocks we next reach are evidently of carboniferous age These occupy a variable strip along the base of the mountains, here and there rising into small hills and ranges

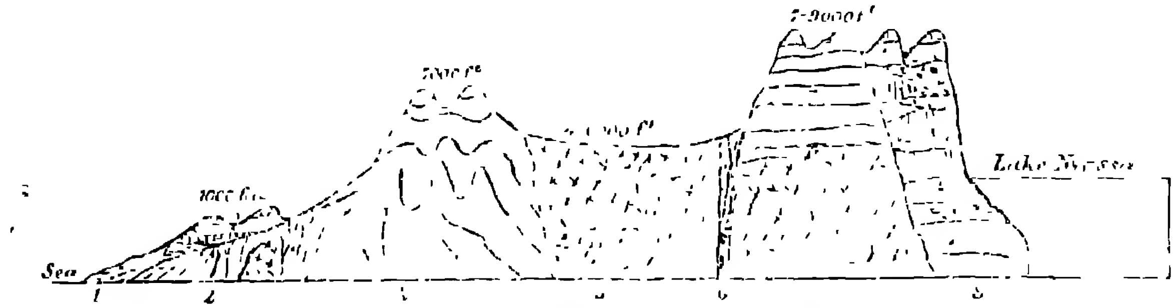
They are found stretching from at least Mozambique to the Equator. On the Rovuma coal-beds are found In the Rufigi valley there are red liver-coloured sandstones with pebbled beds and with interbedded lavas which in one curiously-shaped mountain near Behobeho produce a remarkable step-like appearance. These beds are horizontal, but beneath them are sandstones tilted by the intrusion of eruptive basalts, producing an unconformability which however is probably only local. Further north on the Unyanyembe road from Bogamoyo, and at the base of the mountain I observed on my return march compact beds of fossiliferous limestones, together with shales, &c.

At Umba, a place north of Pangani, I also discovered limestone, which I believe is now being burnt by the Universities Mission Agents. The young geologist, Thornton, the companion of Baron von der Decken, observed this same formation around Mombas, which he noted as being exactly similar to the coal formation of the Zambesi. As no rocks of a later date have been found along the whole of the east coast from Mozambique to the Equator, we may safely infer that this part of the continent has been above water since Carboniferous times, and this inference is strengthened by natural history evidence.

We have now reached the base of the mountains, and again we are brought face to face with another great break in the series of events. From the Carboniferous sandstones and limestones we pass abruptly to highly metamorphosed rocks whose exact place in the geological series is as yet extremely problematical. These consist of the schists, gneiss, and hornblende rocks which form the mountain range that flanks the great Central Plateau extending from Abyssinia to the Cape.

In crossing this range we rose to a height of 7000 feet. We found the strike of the rocks to be north and south They present every intermediate grade of variation from the most coarsely crystalline to those with the bedding still traceable. Indeed it would be somewhat difficult to point out any sharply-defined line of demarcation between the granites, which seem to predominate

in the plateau, and the less metamorphosed rocks It seems to me that this range suggests a line of weakness during the elevation of the continent, owing to which the neighbouring rocks were more easily folded up and raised above the line of greatest pressure, which has turned the main mass of the continent into granite There is however some hope that more definite light will be thrown upon the question of the age of this range, as on my way back to the coast I discovered in the Usagara Mountains some much metamorphosed rocks with imperfectly pre-

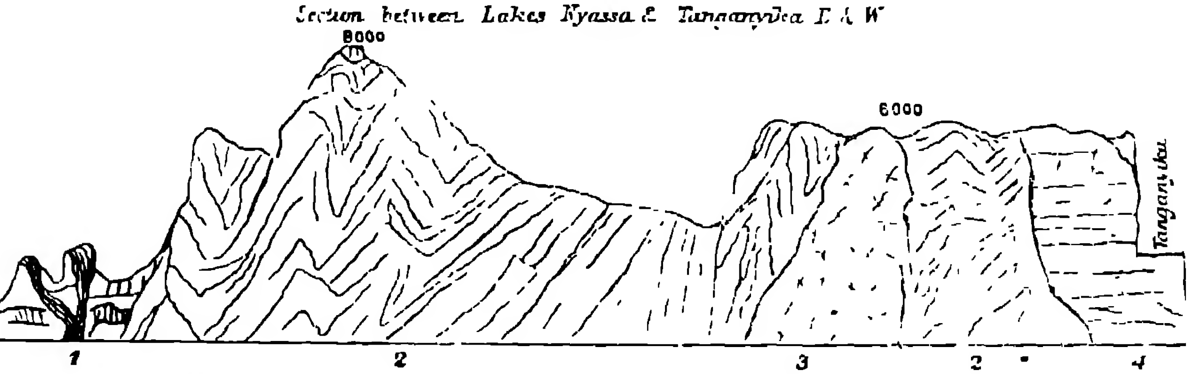


Section of Rocks between Dar-es-salaam and Lake Nyassa 1, Red sandy clays 2, Carboniferous (?) sandstones with intrusive rocks 3 Carboniferous sandstones with interbedded lavas, 4, Schists, gneiss, and other highly metamorphosed rocks, 5 Granite forming main mass of the interior, 6, Intrusive rocks and probable line of fault, 7, Clay slates with occasional felspathic rocks, 8, Volcanic porphyrites, tuffs, and agglomerates

served fossils. A careful search would probably be rewarded by the discovery of fossils which would determine the age of these rocks.

Leaving the metamorphic rocks of the flanking range, we next pass over a great stretch of granitoid rocks This tract, extending to near the lakes, is marked by undulating hills and valleys, with wide areas comparatively level, where the Kaffir-like semi-nomadic tribes of the Wabena, Warori, Wahehi, Wagogo, and Masai herd their cattle, hunt, and live in a constant state of warfare.

Section between Lakes Nyassa & Tanganyika E & W

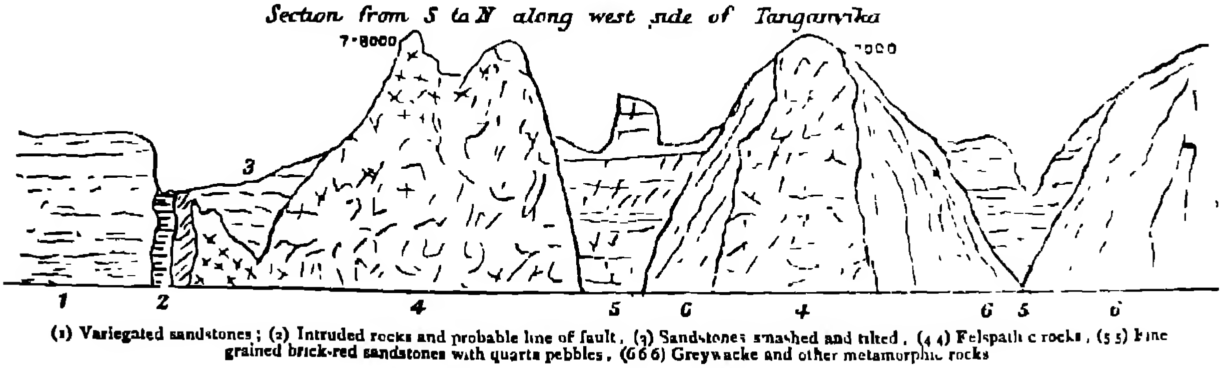


1, Volcanic porphyrites and tuffs, 2 2, Clay slates, schists, and gneiss, 3, Intrusive granite, 4, Variegated sandstones slightly metamorphosed

The influence which the character of the country has upon the habits and manners of savage tribes is here well illustrated.

The soil formed by the degradation of this granite tract is either a stiff red clay as occurs in Ubena and Urori, sandy as in Ugogo, or grey clay as in Unyamwesi The vegetation varies greatly according to the nature of the soil. The whole of this granitoid region is marked by the occurrence of monstrous blocks, generally rounded, and strewing the whole surface as if some great eruption

Section from S to N along west side of Tanganyika



(1) Variegated sandstones; (2) Intruded rocks and probable line of fault, (3) Sandstones smashed and tilted, (4 4) Felspathic rocks, (5 5) Fine grained brick-red sandstones with quartz pebbles, (6 6 6) Greywacke and other metamorphic rocks

had smashed the underlying rocks. Their presence, however, is not due to any such cause, the main agent having been rain and carbonic acid, assisted by rapid radiation acting along the joints and cracks.

It may be noted that at a number of points both in Ubena and Ugogo evidences of rocks erupted through the granites were obtained

Continuing our route to Nyassa over this plateau at a general height of about 5000 feet above the sea we are confronted by a sudden rise in the ground, which forms

apparently a second and higher plateau. The abrupt change of level, together with the alteration in the internal structure and the presence of intrusive rocks at the base of the mountain seem to point to the existence of a fault of considerable magnitude, which probably is the eastward extension of a great fault to be described further on.

The rocks composing this high tract of country consist mainly of clay-slates with the original bedding still very distinct. What may be their exact relations to the granites which they probably overlie, or to the metamorphic rocks of the coast-range, we have as yet no means of ascertaining. Careful research will be required before anything definite can be said about them. The mountains cut out of these rocks by denudation are rounded in form, smooth, and by no means picturesque. They are devoid of trees, but covered with grass

As we approach Lake Nyassa we observe evidence of much disturbance, till at a distance of about ten miles from the Lake we come upon the ancient pipe of a volcano, and five miles further on enter amongst a series of volcanic porphyrites, tuffs, and agglomerates forming mountains several thousands of feet in height, and which extend round the north end of the Lake. Along with this marked change of internal structure we have as decided a change in the scenery The rounded mountains with smooth, grassy, and uncut sides give place to jagged peaks, serrated ridges, sharp yawning valleys, and irregular, rocky, notched sides, forming a landscape of no ordinary description

The extraordinary series of volcanic rocks which form the magnificent mountains round the north end of Lake Nyassa probably belong to the same period as a similar series which characterise the Cape geology The latter have been assigned to the Trias, and doubtless the immense development of volcanic rocks in Abyssinia described by Blandford is of the same age. Indeed we might almost say we have connecting links between the two places, as on my return march through Ugogo I observed evidence of volcanic outbursts, and it is well known that Kilimanjaro, further north, is of volcanic origin. It seems then that in Triassic times a great line of volcanic action stretched from the Cape by Nyassa, Ugogo, and Kilimanjaro, to Abyssinia.

But at the north-west corner of Nyassa we have evidence of later volcanic activity. In a niche cut out of the surrounding plateau and on a comparatively level plain, through which the River Jumbaka winds to the lake, a number of beautifully isolated cones rise to a height of about 300 feet. On examination these prove to be perfect volcanic craters, so entire and symmetrical as to appear almost artificial One crater which I examined forms a beautifully bowl-shaped hollow, descending to the level of the plain, the bottom being a charming circular pond, where a number of hippopotamuses live

It is clear from the perfect shapes of these cones, and from the fact that the surface features of the surrounding country have remained unchanged since their origin, that they must have arisen in comparatively recent times. Besides these cones there are two pretty circular lakes, which also appear to have been originally volcanic craters.

On leaving this interesting country and proceeding on our way to Tanganyika we rise once more to the top of the plateau, cross over mountains 8000 feet in height, and then descend to a general level of from 4000 to 6000 feet. We pass over clay slates and schists whose relative positions could not be determined with intrusive masses of granite At one point an interesting section was revealed, showing the granite completely inclosing a mass of greenstone.

On nearing the south end of Lake Tanganyika we pass abruptly from these ancient rocks to red and variegated sandstones much hardened and broken, but preserving their original horizontal bedding. Rounding the end of the lake and continuing our march northward along its western side, we come to almost a sheer precipice, suddenly lowering the altitude from nearly 5000 feet to less than 3000. Running east and west along the precipice there occur intruded rocks, while on the northern or lower side of the precipice the sandstones almost disappear, being only represented by a small extent of crushed and tilted beds Such a condition of things clearly indicates the existence of a great fault. This theory is strengthened by a similar abrupt change of rocks on the eastern side of the lake, and it will be remembered that we have already noticed among a different series of rocks still further east a sudden change of level almost on the same parallel of latitude.

The sandstones thus abruptly brought to a finish in their extension northward are succeeded by felspathic rocks which form huge mountain masses both on the east and west sides of the lake. Near the middle of the lake on its western side there occurs a curious apparently isolated area of fine red sandstones, surrounded on all sides except the east by mountains of metamorphic and felspathic rocks. These sandstones would seem to have been deposited in a small lake eight miles in diameter. Mount Malumbi, figured in Stanley's "Dark Continent," belongs to the same formation.

Still proceeding along the lake we cross a high mountain range named Tchansa, formed of metamorphic rocks with felspathic rock in the centre We regain the sandstones once more in the country of Uguha The sandstones here, unlike those of the south end, are very red in colour, extremely friable, and marked by the abundance of quartz pebbles. Through this formation the Lukuga River finds its way to the Congo, its course determined not by any great convulsion as some travellers have been inclined to believe, but by the long-continued action of streams wearing down the soft and friable barrier which hemmed in the lake at this point These sandstones have an extension over a large area. They are found away towards Manyema and up the Congo Valley as far as Lake Moero, probably turning round and joining the strata we have noticed at the south end of Tanganyika On the east side they are found from Kaboga to the north of Ujiji, though here shales are not uncommon and the strata much curved

The absence of all fossils leaves the question of the age of these rocks in some mystery A reference to Cape geology may, however, as in the case of the volcanic rocks, throw some light on this subject. The Tanganyika sandstones have evidently been formed in an enormous inland lake, beside which the present African lakes would look insignificant

In Cape Colony a similar series of rocks occur of a lacustrine origin, and which have been assigned to a period not later than the Trias, and probably they belong to Palæozoic times In the absence of anything but lithological evidence we cannot do better than place the Tanganyika sandstones in the same era as the Cape series, an era which would seem to have been emphatically characterised by the presence of great lakes.

JOSEPH THOMSON

INCANDESCENT ELECTRIC LIGHTS

THE recent experiments of Mr. J. W. Swan of Newcastle-on-Tyne have gone far towards demonstrating the practicabilty of a system of electric lighting based upon the so-called principle of incandescence. As the solution of the whole question of the possible domestic application of electric lighting depends in all probability uppon the successful application of this method, these experiments have claimed already a considerable share of public attention, though no panic has yet arisen like

that created two years ago by the far less formidable experiments of Mr. Edison in the same direction.

The material which Mr. Swan proposes to render incandescent by means of an electric current is a "wire" of prepared carbon of extraordinary density and elasticity. Twenty years ago he prepared carbon filaments for the very same purpose from calcined cardboard, inclosing them in a glass vessel from which the air was withdrawn as perfectly as the imperfect air-pumps of that date permitted. In October 1877, or one year before Mr. Edison had begun to attempt the construction of lamps with carbonised paper, Mr. Swan had some prepared carbons mounted in glass globes and exhausted by the Sprengel air-pump by Mr. Stearn of Birkenhead. This enabled Mr. Swan to discover that when the carbon was properly fixed and heated during exhaustion so that the occluded gases might be expelled, there was an end of the causes that hitherto had seemed to defeat all attempts to utilise this method of procuring an incandescent electric light, for when these conditions were observed there was none of the disintegration of the carbon rods, nor of the blackening of the globes that with less perfect vacua had proved the ruin of carbon lamps. The filaments of carbon now produced by Mr. Swan indeed resemble steel wire rather than carbon, so extraordinary is their tenacity and texture. The secret of their manufacture has not yet been made known, being the essential point of the patent rights which Mr. Swan has just secured. Each filament is about three inches long, and not more than the hundredth of an inch in diameter, and is so slight as only to weigh from one-fifteenth to one-twentieth of a grain. The durability of these filaments is remarkable. In the course of a lecture delivered on November 25 last before the Society of Telegraph Engineers, Mr. Swan stated that he had had lamps lighted continuously since August 30, with an intermission of three weeks only, and that this seemed to be far from the actual limits of durability. When the currents employed are not too strong, the lamps will last longer. The light yielded by these lamps varies, according to circumstances, from thirty to fifty standard candles. On the occasion of Mr. Swan's lecture thirty-six of these tiny lamps were exhibited working by the current of a dynamo-electric machine requiring four horse-power to drive it. In the debate which followed Mr. Swan's communication, the remarks made by Prof. Tyndall, Dr. Hopkinson, Mr. Alexander Siemens, and others, showed the real value of the advance made by Mr. Swan. The question however of the economy of the system remains yet to be decided by the practical test of durability. At a previous lecture at Newcastle-on-Tyne Mr. Swan exhibited twenty lamps fed by a current generated by a gas-engine consuming 160 cubic feet of gas per hour. The light obtained exceeded that of the seventy gas-jets which usually supplied the same room, and which consumed 280 feet per hour. Mr. Swan proposes to connect these lamps in series of fifty or a hundred in one circuit, using automatic circuit-closers to close the circuit in the rare case of the failure of a lamp. He considers his method of arranging the system to be superior to that proposed by Mr. Edison, whose method of placing the separate lamps in single branches of a divided circuit would involve the use of very heavy and costly conducting-wires without any counterbalancing advantage. With this important difference Mr. Swan's further proposal to erect central stations from which to supply currents of electricity over large areas resembles that suggested by Mr. Edison. Should the anticipations of the inventor and the present promise of the new lamps be fulfilled, domestic electric lights will certainly become a fact at no distant date.

Meantime Mr. Edison has not been idle. It is stated that he is at present laying down a service of about seven miles in length upon which to test the success or failure of his system upon a large scale. He has developed several ideas since his last appearance before public notice. He now makes his dynamo-electric generators of a much larger pattern than any heretofore attempted. He has abandoned charred cardboard in favour of a filament of carbon prepared from a cultivated variety of the Japanese bamboo. We shall hear before long whether his indomitable perseverance has been rewarded with final success. In spite of being in point of date behind Mr. Swan, he has the enormous advantages of a unique workshop and laboratory under his own direction, of a wealthy company at his back, and of the extraordinary prestige won by his previous inventions. If Mr. Swan appears to be nearer to a genuine success, Mr. Edison has a popular reputation that of itself will win a hearing for the most trivial of his inventions. Whichever of the rival systems succeeds science and mankind are the gainers. But up to the present point it seems to us that beyond question Mr. Swan is nearer the goal of practical results than his famous rival.

It may interest our readers to know that Mr. Edison's first carbon lamp is now on view along with his original phonograph and his earliest tasimeter in the Patent Museum at South Kensington.

SUBTERRANEAN FOREST IN INDIA

THE accompanying notes and illustrations on the underground forest recently discovered in excavating the Prince's Dock, Bombay, were forwarded by Col. C. J. Merriman, R.E., C.S.I., Member of the Legislative Council, and Secretary to Government (Public Works Department), Bombay.

The trees were generally found in a dark loamy soil composed of underlying rock disintegrated. The upper

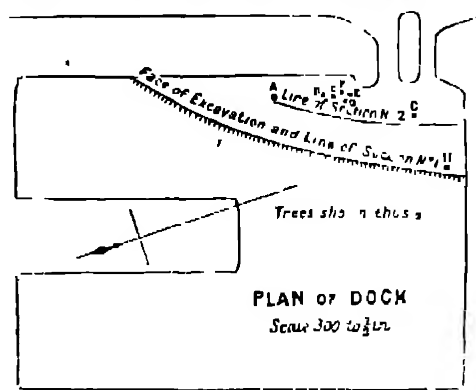


FIG. 1.—Dock.

portion of the trunks stopped at the soft black clay, which is silt. A few went a little way beyond, but as far as they protruded into the silt they were completely

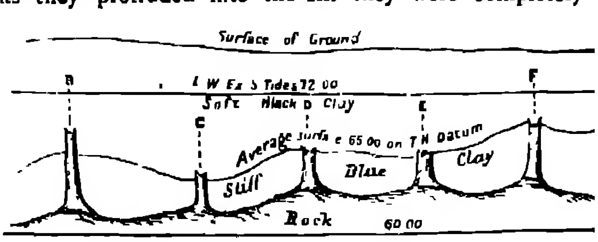

FIG. 2.—Section in line of trees B to F. Scale $\frac{1}{16}$ inch to 1 foot.

riddled by the teredo, the nearer the root the bigger the hole, showing that the boring began from the top.

The roots of the highest tree found were at 72·20 on T.H. datum, or close on Low Water extreme springs, about six feet under the surface of the mud. The lowest root was

at 55·93, or say sixteen feet under L.W. extreme springs, twenty-two feet under the surface of the mud

Inside the dock altogether were 382 trees, 223 standing, the remainder flat. The largest tree was forty-six feet long, and 4′ 6″ girth; it was flat None of the trees would girth over 4′ 6″. The soil in which many of them stood was only 6″ to 9″ thick over the rock. The wood is apparently black wood. The roots presented a peculiar appearance, being nearly at right angles to the trunks

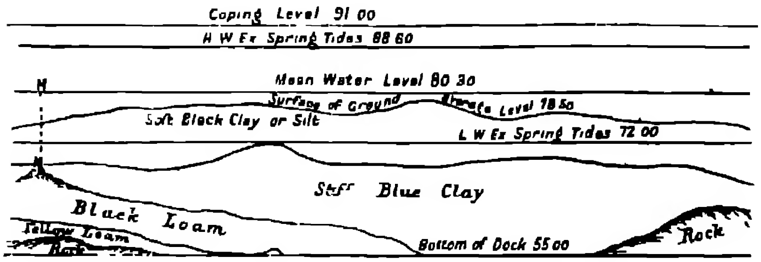

FIG 3 —Section No 1 Scale—Vertical 15 feet to ⅛ inch, horizontal 150 feet to ⅛ inch

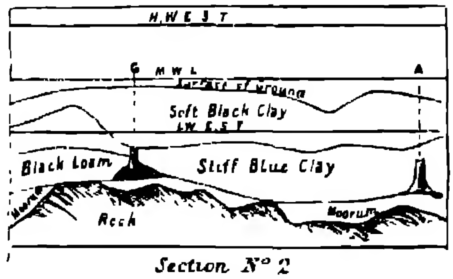

FIG 4 —Section No 2

The forest seems to have stopped at the gates, as very few trees were brought up in the dredging operations.

The mixture of different kinds of stone is curious. In small patches we find trap, which gives way to moorum, and then a sort of pudding-stone mixed up with black and red stuff so hard that it cuts the divers' hands as with a knife.

NOTES

PROF. HELMHOLTZ has been appointed Faraday Lecturer for 1881, the lecture will be given early in April

WE greatly regret to announce the death of Sir Benjamin C. Brodie, Bart, F R S., the eminent chemist and late Professor of Chemistry in the University of Oxford He died on Wednesday, last week, at Torquay, in the sixty-fourth year of his age. We hope to be able to give a detailed notice of Sir Benjamin's life and work in a future number.

THE death, on Sunday, is announced of Mr Mark Firth, at Sheffield, in the sixty-second year of his age Mr Firth was eminent for his discriminating liberality, and will be specially known to our readers as the founder of the well-known Firth College, Sheffield, opened by Prince Leopold last year

PROF. J CHARLES D'ALMEIDA, whose sudden death at Paris we mentioned a fortnight since, was one of the prominent leaders in the scientific circles of the French capital. Formerly a Professor of Physics in the Lyceum of Henry IV, he had occupied for some years past the important and responsible position of Inspector-General of Public Instruction. A strong Liberal in matters of education, he exercised a marked influence in the late reorganisation of the French educational system. It was almost entirely owing to his efforts that the Société Française de Physique owes its creation, and since its origin he has occupied the post of secretary. As an investigator D'Almeida is best known by his valuable researches on the phenomena of electrolysis, on galvanic batteries, on capillary phenomena, &c. One of the most remarkable services he has rendered was the invention of the photographic despatches by means of which, during the siege of Paris, the inhabitants of the city were enabled to avail themselves so extensively of the otherwise limited services of the "pigeon post."

A SHORT time ago we alluded to the severe loss to chemical and technical literature by the death of Prof von Wagner, who for twenty-five years past has conducted so ably his admirable *Jahresbericht für die chemische Technologie* The difficult question of finding a successor in the editorship of this important annual has been happily solved by the choice of Dr. Ferd. Fisher, Professor of Technology at the Polytechnic of Hanover. For a long time past Prof. Fisher has rendered valuable literary services in editing *Dingler's Polytechnisches Journal*, the most important technical publication on the Continent. As an investigator he is also well known by his elaborate researches on water in its technical and physiological relations, on pyrometry, and on numerous other chemical and technical questions. Under the new auspices the *Jahresbericht* has every reason to look forward to a continuance of its successful career.

M. CHARCOT reopened last week his course of botany at Salpetrière, where he exhibited last year the curious phenomena of female patients suffering from neuro-mental affections New instances will be produced of cures analogous to the troubles regarded in mediæval times as produced by demoniacal agency or cured by witchcraft.

IN a lecture on earthquakes delivered in Vienna on the 22nd inst, Prof. v Hochstetter designated the Agram earthquake (affecting elliptically a region of 60 to 80 German miles diameter, and having its larger axis directed south-south-west to north-north-east) as a tectonic or dislocation-earthquake—a name which originated with the Austrian geologist Prof Hornes. Prof. Suss expressed a similar opinion in a lecture on November 24, "On Earthquakes in the Alps."

ON Sunday evening, about six o'clock, slight shocks of earthquake were felt at two different places in Scotland—one being Callander, in Perthshire, and the other Inverary, in Argyllshire. The two districts affected are about forty miles apart, in a line due east and west The shock was also felt at Rothesay and Stornoway. In the north of Ireland during Sunday evening and also the earlier hours of yesterday morning several decided shocks of earthquake were felt, especially in Londonderry and its vicinity. The disturbance was more particularly felt at Innishowen, and it seemed to travel across the bed of the River Foyle to the County Derry side, where the effects were felt strongly.

AT DORTMUND there was a slight shock of earthquake on November 25, and a smart one on the 27th.

MR. MUNDELLA has been speaking on education again, repeating essentially the old story, that our country must lose in the race unless, as in other countries, education in science is made an imperative part of elementary education. We have many natural and traditional advantages over other countries, but all these must in the long run succumb to scientific training.

A MAGNIFICENT lacustrine find has been made in the marshes of Corcelletes, near Consise, in Canton Vaud. It consists of a

fine canoe in a perfect state of preservation, 11 metres 16 centimetres long, and slightly more than a metre broad. It was dug out and drawn from the marsh by sixty men and eight oxen, under the superintendence of the director of the Museum of Lausanne, and has been placed in the court of the Lausanne Academy, where it is destined to remain.

WE have before us the reports for last year of the two clubs which have for their object the furtherance of the special study of British plants and their distribution over the surface of the islands. The Botanical Exchange Club has been in existence about twenty-five years, and was a continuation of the London Botanical Society. The Secretary sends out each spring a list of the plants that are wanted, and the members, who are about thirty in number, at Christmas send in their parcels and lists of desiderata. All doubtful specimens are submitted to competent referees, and after the distribution is made a report is published on critical forms and extensions of distribution. The most interesting find noticed this year is the discovery of *Herniaria hirsuta*, a plant spread widely through the southern half of Europe, by Mr. Fred. Townsend at Christchurch, in Hampshire. Dr. Boswell identifies the prickly comfrey, which has been so much talked about lately as a forage plant, with the *Symphytum uplandicum* of Nyman. Probably it is really a hybrid between *S. officinale* and *S. asperrimum*, as was suggested lately when it was figured by Sir Joseph Hooker in the *Botanical Magazine* Some curious observations have been made lately tending to show that our wild docks hybridise naturally not unfrequently, like verbascums, geums, primulas, thistles, and epilobia. There is a curious form of *Ophioglossum* (*O vulgatum*, var. *ambiguum* of Cosson and Germain), which till now has been known in Britain only in the Orkney and Scilly Islands. This year Mr Chas. Bailey has found it on the Welsh coast between Harlech and Barmouth The Botanical Record Club has for its object the filling up of the blanks left by Mr. Watson when he traced out in detail the home-distribution of British plants in his "Cybele Britannica.' In the report for this year detailed lists are given for Cardiganshire and Peeblesshire, and the only counties for which lists of flowering plants now remain to be drawn up are Flintshire, Wigtonshire, and West Ross. Fourteen pages of the present report are occupied by fresh records for counties already worked up, and the Club is now turning its attention to the distribution of the lower cryptogamia, especially mosses. The registration of flowering plants is in the hands of Dr F A. Lees of Wetherby, and of mosses in that of Mr. H. Boswell of Oxford, and the Secretary of both the Clubs is Mr Chas. Bailey, F L.S, of Manchester

MR. BRIAN HOUGHTON HODGSON, F R.S, has just presented to the Anthropological Institute a valuable portfolio of drawings illustrative of the Eastern Himalayas and Tibet The drawings have been made by the same Nepalese draughtsman as delineated the zoological drawings which have been presented to the Zoological Society, and this ethnological series comprises and contains in all 521 subjects, including duplicates A series of crania have been drawn by aid of the camera, Mr. Hodgson remarking "native patience, hand and eye being peculiarly fitted to work that instrument."

ETIENNE MULSANT, one of the most prominent of French entomologists, and librarian to the city of Lyons, died on November 4 at the great age of eighty-four. His earliest publication was the "Lettres à Julie sur l'Entomologie (en prose et en verse)," published in 1830, but for the most part consisting of real love-letters to the lady he afterwards married, and written before he was out of his teens. His writings are most voluminous, but he was best known as the author of a work extending over nearly forty years, on the *Coleoptera* of France, and published (chiefly) in the *Annales* of the Linnean Society of Lyons. He was also the author of a magnificently illustrated work on Humming Birds, in connection with which he visited London about five years ago.

WE learn that Messrs Williams and Norgate are about to issue an important work on the Fishes of Great Britain and Ireland by Dr. Francis Day, late Inspector General of the Fisheries of India. This work deals with their economic uses, modes of capture, diseases, breeding, life history, &c., with an introduction on the structure of fishes generally, their functions and geographical distribution. The first part appears this month, and is illustrated by twenty-seven plates. The whole will form a work of 700 pages royal octavo, with over 200 plates

THE exploration of the remains of prehistoric man is being actively carried out in Russia. We have already briefly noticed a contribution to this subject by M. Mereshkovsky, published in the *Izvestia* of the Russian Geographical Society (vol xvi No 2), being a report upon the exploration of caverns and rock shelters in the Crimea, in the neighbourhood of the Tchatyrdagh Mountain A great cavern, 145 feet wide and 58 feet deep, was explored close by the Suren town, and M. Mereshkovsky found there the remains of a prehistoric workshop for the manufacture of stone implements, the whole belonging to two distinct periods. The paper by M. Mereshkovsky, published in the *Izvestia*, is accompanied with four tables of drawings of stone implements

WE notice the following interesting communications which were made at the last meeting of the St Petersburg Geological Society:—On the motion of downs near Sestroretsk, by M Sokoloff. The velocity of these downs is about one foot per month.—On the excavations made by water in rivers and springs of Northern Esthonia, especially by the waterfalls near Reval, Yagowal, and Fal; and on the Devonian clays discovered by Prof. Inostrantseff in the cuttings of the new Ladoga canal. The upper parts of the beds of these clays are bent by the action of the ice of the ice period, as has been observed at many places in Great Britain, the peats which cover the glacial formations are full of remains of prehistoric man.

WE can state that the Observatory of Algiers will not remain longer without an astronomical observer M. Tripier, who has been appointed director, as has been announced in the French papers, will leave in time for installation at the meeting of the French Association for the Progress of Science in April, 1881

THE purchaser of the French Siemens patent is preparing to send a tender for establishing an electric railway from the Exhibition to the central parts of Paris

ABNORMAL VARIATIONS OF BAROMETRIC PRESSURE IN THE TROPICS, AND THEIR RELATION TO SUN-SPOTS, RAINFALL, AND FAMINES[1]

II.

Comparison of the Abnormal Barometric Variations with the Sun-Spots

A GLANCE at the barometric and sun spot curves is sufficient to show that the irregular and frequent fluctuations of pressure are relatively much larger than those of the sun-spots In order therefore to compare the general course of the barometric curves with that of the sun-spot curve the numbers of Table I have been further smoothed by taking the means of every nine consecutive quarterly values of the nine monthly means. The results of this operation are given in the following table, and graphically represented by the dotted curves which are drawn through the continuous ones. All these dotted barometer curves closely resemble each other, except that portion of the Mauritius curve after the year 1865 which shows a tendency to assume an opposite character. They are also very similar to the sun-spot curve, but all of them lag very persistently behind the latter, as will be seen by comparing the points marked with the same capital letters.—

[1] Continued from p 91

The epochs of maximum and minimum barometric pressure and of minimum and maximum sun-spot area, as determined from the dotted curves by the graphic method, are given in the following table —

Epochs of Maximum and Minimum Barometric Pressure and Solar Spotted Area

Solar spotted area	Barometric pressure: St. Helena	Mauritius	Bombay	Madras	Calcutta	Batavia	Zi-ka-wei
Min in July 1843	Max in Nov 1845	—	—	Max. in Aug 1845	—	—	—
Max in May 1848.	—	—	Min in Sept 1848.	Min in Dec 1848	—	—	—
Min in April 1856	—	Max in Oct. 1858	Max. in Aug 1858	Max. in Aug 1858.	Max. in Sept 1858.	—	—
Max in June 1860.	—	Min. in April 1862	Min. in Aug 1862	—	Min. in Jan 1863	—	—
Min in February 1867.	—	?	Max. in May 1868.	—	Max in Nov. 1867	Max in May 1868	—
—	—	?	Min. in Sept. 1870.	—	Min. in Nov. 1870.	Min. in Dec 1870	—
—	—	—	Max. in April 1877.	—	Max in Sept. 1877	Max in May 1877.	Max in Sept. 1877.

The mean epochs are given below and compared with those of the solar spotted area.

Mean Epochs of Barometric Pressure compared with the Corresponding Epochs of Solar Spotted Area[1]

Solar spotted area			Barometric pressure			Difference	
	a			b		$b-a$	
	Year	Month		Year	Month	Year	Month
Min.	1843	7·5	Max	1845	10·0	+2	2·5
Max.	1848	5·5	Min	1848	11·0	+0	5·5
Min.	1856	4·5	Max	1858	9·2	+2	4·7
Max.	1860	6·5	Min	1862	8·8	+2	2·3
Min.	1867	2·5	Max.	1868	3·5	+1	1·0
				Mean		+1	8·0

From this comparison it appears that the epochs of maximum and minimum barometric pressure lagged behind the corresponding epochs of minimum and maximum solar spotted area at an interval varying from above six months to nearly two and a half years, or at an average interval of about one year and eight months.

Making use of this result and comparing points of the pressure curves with points of the solar curve several months earlier, it will be seen that even the minor peculiarities of the pressure curves from 1863 to 1868 do bear some resemblance to the subordinate features of the sun-spot curve from 1862 to 1867. What appear to be corresponding points have been marked with corresponding letters. It is remarkable that this part of the sun-spot curve is the very portion which has been most accurately determined by means of the Kew photoheliograph.

Comparison of the Abnormal Barometric Variations with Past Famines.—According to the Report of the Famine Commission the famine of 1876-78 in Southern India was *the most widespread and severe* of any which have occurred in India during the present century, and on reference to the curves it will be seen that the abnormal barometric pressure during those years was the *highest on record*. In the year 1878 a famine occurred in the North West Provinces also, in consequence of a deficiency of rain in the previous year.

The famine next in severity to that of 1876–78, and of even greater extent, was the one of 1868–69, which affected Rajputana and the North-West Provinces. The curves show that this also was accompanied or immediately preceded by a *wave of high barometric pressure*, which reached its maximum near the middle of the year 1868.

The next on the list of severe famines is that which occurred in Orissa in the years 1865–66, and it will be seen that this also was attended by a *wave of high pressure* which slowly passed over India in the years 1864–65.

The less extensive Behar famine of 1873-74 was also accompanied by a small wave of high pressure, which, judging from the curves for Mauritius, Bombay, Madras, and Batavia, reached its maximum height towards the end of 1873.

The famine of 1860-61 in the North-West Provinces was also preceded by a wave of high pressure in the year 1859, although the failure of the rains which induced this famine did not occur till the following year.

The above mentioned famines include *all* the severe ones that have occurred in India since 1841, the year from which barometric data exist; and the waves of high barometric pressure which have been mentioned in connection with them include *all* that have been observed except two, viz. the one in 1855 and the one in 1845, both of which, though not immediately followed by actual famine, were nevertheless accompanied by deficient rainfall both at Madras and Bombay, the fall at the former station being 67 and 78 per cent. of the average in 1855 and 1845 respectively, and at the latter station 58 and 77 per cent. in the same years. Between the years 1832 and 1840, during which the solar spotted area was accurately observed, but for which period I have no barometric data, two other severe famines occurred, viz. the Guntur famine of 1833, and the famine of 1837-38 in Northern India; and it is worthy of note that the first of these occurred soon after the sun-spots had somewhat suddenly fallen to a minimum in 1832, and when, therefore, the barometric pressure would assumably be high, the second soon after the great and sudden diminution of spots which took place early in the year 1837. This last occurrence was very similar to the great decrease of spots observed in 1863, on which occasion

[1] The numbers 1, 2, 3, &c., under the heading "Month," refer to the months January, February, March &c., respectively, and the decimals of a month are reckoned from the beginning of the respective months.

the decrease was followed by the wave of high pressure which preceded the Orissa famine.

Hence it appears that widespread and severe famines are generally accompanied or immediately preceded by waves of high barometric pressure.

Means whereby future famines may possibly be foreseen.—If the conclusions arrived at from the above comparisons of abnormal barometric variations, sun-spots, and past famines be admitted, it is clear that they at once present the means whereby future famines may possibly be foreseen. The conclusions are briefly:—

1. That variations of the solar spotted area are *succeeded many months afterwards* by corresponding abnormal barometric variations.

2. That abnormal barometric variations in the tropics travel at a very slow rate round the earth from west to east, arriving at westerly stations *several months before* they reach more easterly ones.

3. That famines follow in the wake of waves of high barometric pressure.

Hence it follows that there are two methods by which early intimation of the approach of those meteorological disturbances which are attended by famines may possibly be obtained—

1. By regular observation of the solar spotted area, and early reduction of the observations, so as to obtain early information of current changes going on in the sun.

2. By barometric observations at stations differing widely in longitude, and the early communication of the results to stations situated to the westward.

With regard to the first of these methods it is sufficient to state that the whole subject of solar observations is now being investigated by a committee of scientific gentlemen in London, and we may therefore hope that the all-important information which solar observations are capable of affording will ere long be at our disposal; but with regard to the second method, viz., that of barometric observations at stations differing widely in longitude, it is to be regretted that no observatories of long standing situated in suitable localities to the *westward* of Bombay at present exist, except possibly at the very distant station of Havanna in Cuba. The observatory at St. Helena appears to have been closed in the year 1847, after working continuously for about seven years.

The most suitable localities for barometric observations for the purpose in view are insular stations far removed from the disturbing influences of the large continents and near the equator, such as the Seychelles, St Helena, and Ascension, but these appear to be at present unoccupied by permanent observatories, while the wide expanse of the Pacific, which is probably the most suitable portion of the earth's surface for investigations of this kind, appears to be entirely unrepresented by any fixed observatory on any of its numerous islands, such as the Galapagos, Sandwich, and Fiji Islands. An observatory has however lately been established at Zanzibar on the East Coast of Africa, from which very valuable observations may be expected if it should continue at work for any great length of time, and another has, I believe, been started at Aden: but as these stations are both situated on the borders of extensive continents, they are not so suitably located as the stations previously mentioned.

It would therefore be necessary, in order to utilise to the fullest extent the second method of foreseeing the approach of a meteorological disturbance of the kind which would probably be attended by famine, that special arrangements should be made for the registration of the needful observations at some, if not all, of the stations that have been referred to, and that the information thus afforded should be rapidly communicated from the more westerly to the more easterly stations.

F. CHAMBERS,
Meteorological Reporter for Western India

Bombay, September 4

POSTSCRIPT.—In order to determine numerically the intervals of time at which the barometric variations of one station have lagged behind those of another, and behind corresponding minor variations of the sun spots, the times at which the continuous curves cross the dotted ones have been marked off by the graphic method for corresponding crossing points of the different curves, giving the first set of times and intervals in each of the following tables. The same thing has been done with regard to the times at which the continuous curves cross the respective zero lines, giving the second set of times and intervals in each of the tables. As the average pressures for Batavia and Bombay have not been calculated from the observations of the same years, and as the zero line of the Batavia curve is on this account relatively displaced by ·004 of an inch in the upward direction, a new zero line has been drawn so as to make the times at which the continuous curve crosses the zero line comparable with those for Bombay. The approximate longitudes of the stations and their differences are also given in the tables.

It will be seen that in the great majority of cases the barometric waves reach the westerly station several months before they arrive at the more easterly one, but that the rate of progression of these waves across the Indian Peninsula appears to be much slower than across the open ocean to the southward

F. C.

THE ROYAL SOCIETY—ADDRESS OF THE PRESIDENT[1]

DR SPOTTISWOODE began by referring to the losses which the Society has sustained by death during the past year:—Prof. Miller, Dr Sharpey, Mr Lassell, Prof Ansted, Lord Belper, Mr E W. Cooke, and Sir Benjamin Collins Brodie.

The Society's finances generally are, as the balance sheet will show, in a healthy condition, and appear to justify the hope that they will suffice for the large claims upon them for printing our publications The address then proceeds:—

Although we are more concerned, Dr Spottiswoode said, with the quality than with the quantity of communications made to the Society, it may not be without interest to observe that the number of papers received this year has been in excess of that in any previous year, at all events since 1872, inclusive. The following is a table of the numbers during the last nine years —

1872	99	papers received
1873	92	,, ,,
1874	98	,, ,,
1875	88	,, ,,
1876	113	,, ,,
1877	97	,, ,,
1878	110	,, ,,
1879	118	,, ,,
1880	123	,, ,,

and we may conclude that these have contained good matter from the fact that of the *Philosophical Transactions* for the current year Parts i and ii., already published, contain no less than 900 pages and thirty-three plates.

Dr Spottiswoode then referred to the satisfactory results of the change of time of meeting of the Society, and went on to speak of the death of Mr Henry White, who for many years was chief assistant in the compilation of the great Catalogue of Scientific Papers. At an earlier stage of the work, Dr. Spottiswoode went on to say, his loss would have been still more serious, but in a long course of training he succeeded so well in imparting his own careful and methodical mode of work to those under him, that the Council felt justified in making trial of his son to take his place With the result of this trial, as shown in continuing the preparation of a new edition of the catalogue of the Society's Library, the Council has reason to be satisfied Of this new edition, the first portion, 220 pages, containing our large collection of *Transactions* and *Proceedings* of Academies and Societies, and other scientific periodicals is in type, and will shortly be printed off. The verification of titles of our scientific books generally is so far advanced as to warrant the expectation that a large instalment of this portion of the catalogue will soon be in the printer's hands; after which we anticipate no further delay

In regard to the Library, a question has arisen as to how far purely literary works, which occupy much space, should be retained. Among them there are doubtless some which add neither to the utility nor to the scientific importance of our Library, but there are also some early printed books, bibliographical treasures, which are worthy of a place in any collection. It is proposed to have these carefully put in order, and to place them in a case by themselves. Among these, there may be mentioned —

Caxton's Chaucer, 1480.
Pynson's Chaucer, 1492
Speght's Folio Chaucer, 1598.
Ciceronis Officia et paradoxa, Fust, 1466, vellum
The generall historie of Virginia, Lond 1632
Bonifacius. Sextus decretalium liber. Ven. 1566 7
Plautus, 1482. Seneca, 1490
Ovid, 1485 Statius, 1490.
Plutarch, 1485. Herodotus, 1494
Homer, 1488.

For bringing into prominence these as well as other features of our miscellaneous, *i e.* non scientific, books, we are greatly indebted to the care and knowledge brought to bear on the subject by Mr. Tomlinson, and by our treasurer.

Although it is doubtless undesirable to propose, without sufficient cause, alterations in our statutes, or even in our practice, it is still often worth while from time to time to discuss questions involving such alterations in order that we may be prepared for a

[1] Address of William Spottiswoode, D C L, LL D, the President, delivered at the Anniversary Meeting of the Royal Society on Tuesday, November 30, 1880

deliberate judgment whenever occasion may arise. Among such subjects there is one upon which I have often heard opinion expressed, and upon which opinion has always weighed in the same direction: I allude to the period of office of those elected to serve on the Council of the Society. By the terms of our charter ten of the ordinary members retire every year; and as it is our custom to remove six according to seniority and four in respect of least attendance, it rarely happens, although the contrary is possible, that any Fellow, except those holding the posts of President, Treasurer, or Secretary, should remain in office more than two years. Experience, however, appears to show, that for a member serving on the Council for the first time, there is so much to learn, so many heads of business which do not in general come before the Fellows at large, that his first year is occupied quite as much in ascertaining his duties as in actively performing them This objection is in some degree met by selecting for the ten incoming members five who have served before, and five who have not so served, but, nevertheless, there is usually an interval of several years between two periods of office, and as a matter of fact we often lose a member of Council at the moment when his advice is becoming most valuable to our body.

I am aware of the great convenience attaching to our present impersonal mode of selecting the members to retire in each year, and am not at present prepared to suggest any specific alteration. But the great confidence which the Society has, especially of late years, placed in its more permanent officers, and the power which naturally accrues to them from the comparatively short tenure of office by the other Members of Council, appear to me to be points of which the Society should not lose sight. On the part of the officers I think it right to state that we are very sensible both of the honour which is thus done to us and of the responsibility which is thereby entailed, and that we hope never to discredit the one nor to abuse the other And having said so much, we are quite willing to leave the matter in the hands of the Society to be taken up whenever they see reason so to do.

It will be in the recollection of the Fellows that the position of the Royal Society in respect of the Government Fund of 4000*l*. per annum is different from that in relation to the Government Grant of 1000*l*. per annum In the latter case the sum is placed unreservedly in the hands of the Society for promoting scientific investigation, subject only to an annual report to the Treasury of the disposal of it; and, in administering it, the Society has in no case applied it to the personal remuneration of the applicant. In the former case the Society has been requested to advise the Science and Art Department as to the distribution of the grant, not only for the direct expenses of investigations, but also for personal remuneration for the time expended on them, whenever the circumstances and wishes of the applicant appeared to render this desirable. The responsibility of this advice lies with a Committee similar to that of the Government Grant, but with the addition of the presidents of certain learned bodies and societies, nominated for that purpose by the Government.

The recommendations made by the Committee each year are annually published in the *Proceedings*, so that the public will have had full information as to the distribution of the grant; while the Fellows have the opportunity of seeing the nature of applications made, and the extent to which it has been found practicable to meet them, as recorded in the minutes of the Council of the Society.

One of the points which is perhaps beset with the greatest difficulty is that of the so-called "personal" grants. On the one hand it has been argued that it is desirable to enable the man of small means to devote to research a part of his time which he could not otherwise afford to give; but, on the other, the question has been raised whether it be wise, even in the interests of science, to encourage any one not yet of independent income to interrupt the main business of his life. It is too often assumed that a profession or a business may be worked at half-speed, or may be laid down and taken up again, whenever we like. But this is not so, and a profession temporarily or even partially laid aside, may prove irrecoverable; and the temptation to diverge from the dull and laborious path of business may prove to have been a snare. Without proposing to exclude from possible aid in some shape or other those cases where personal assistance may be safely offered, it has been suggested that many such cases may be practically met by grants for the employment of an assistant, instead of grants to the applicant himself.

There is another fundamental difference between the position of the Government Grant of 1000*l*. per annum and the Government Fund of 4000*l*. per annum, which appears to me to be of material importance in the interests of science. The former is an absolute grant from the Treasury made to the Society for scientific purposes. It may be used wholly, or in part, during the year in which it is made, and the balance, if any, may be carried over by the Society to the next or even to succeeding years. The latter is a vote to the Science and Art Department, on the disposal of which the Society is consulted. Like all other similar votes, any unused balance reverts to the Treasury, and is to that extent lost to the purpose for which it was intended. I cannot help thinking that, if any such balances could be reserved and kept in hand, provision might be made for some larger purposes than those to which the fund has hitherto been devoted. And, even if having this end in view, the Committee should not see its way to recommend some of the smaller applications, it may be fairly questioned whether the smaller grants might not find a more appropriate place among those of the Donation Fund of this Society, or of the British Association, or among some of those separate funds which, through the liberality of individuals, are now growing up among the special societies.

I am glad to record the fact that, upon the recommendation of men of science, Her Majesty has been pleased to grant pensions on the Civil List to the widows of two of our late Fellows, viz., to Mrs. John Allan Broun and to Mrs Clifford.

Last year two volumes containing a collection of the late Prof Clifford's general lectures and essays were brought out. It is hoped that during the present winter a collection of his mathematical papers will be published. The contributions to science by the late Prof Rankin have recently been placed in the hands of the public While very sensible of the obligations under which the scientific world is placed by these posthumous publications, I cannot refrain from alluding to our obligations, even greater if possible, to those who during their lifetime are willing to re-issue their own scientific memoirs, and to give us thereby not only the convenience of ready access, but also the advantage of their own subsequent reflections on the subjects of which they have treated. And at this particular moment I desire to mention more particularly the mathematical and physical papers of our Senior Secretary, Prof. G. G. Stokes; and, while expressing our gratitude for the volume which has already appeared, I would express also our sincere hope that another instalment from the same source may shortly follow.

Among the subjects which at one period of the late session of Parliament engaged the attention of the Government was that of the law relating to vaccination, and a Bill was introduced intended to remove some of the practical difficulties in carrying out the existing law While fully admitting the difficulties in question, the remedy proposed appeared to trench so closely upon the application at least of a scientific principle, and at the same time to be so important in its practical aspect, that I ventured (although the Council was not sitting) to consult the Presidents of the Colleges of Physicians and of Surgeons, and that of the Medical Council, about addressing the Government on the subject. This resulted in a joint deputation to the President of the Local Government Board, in which I took part as President of the Royal Society. I reported this matter to the Council at their first meeting after the recess, and received their approbation The Bill in question was withdrawn

The Royal Commission on Accidents in Coal Mines, the appointment of which I mentioned in my address of last year, has been occupied principally in bringing together a body of valuable evidence on the causes and prevention of accidents in mines generally. The Commission has also visited a number of mines in which serious accidents by explosion have taken place, or in which certain phenomena connected with the occurrence of fire-damp were to be studied. They have also instituted a series of experiments on the behaviour of various safety lamps in mixtures of natural fire-damp and air. These experiments they are about to renew during the winter. They also contemplate carrying out experiments in blasting rock and coal by methods which will check the production of flame, and which are thereby calculated to obviate the danger of igniting fire-damp.

The report of the voyage of H.M.S. *Challenger*, to which the scientific world has been looking forward with so much interest, is now so far advanced that one volume of the "*Zoological Memoirs*" will appear immediately In addition to this a second volume may be expected within a year. The first volume of the whole work, "containing a short narrative of the voyage, with all necessary hydrographical details, an account of the appliances and methods of observation, a running

outline of the results of the different observations; and a chapter epitomising the general results of the voyage," together with the second volume containing the meteorological, magnetic, and hydrographic observations, will probably be published within the same period "The general report on the zoology of the expedition will consist of about fifty distinct memoirs, which will occupy from ten to twelve volumes." It has been arranged "to print the Zoological Reports as they are prepared, and to publish them as soon as a sufficient bulk of memoirs is ready to form a volume. Copies of each memoir may also be had separately, in order that working naturalists may have them in their hands at the earliest possible date." Two more volumes on the geology and petrology, and one on the general chemical and physical results, will probably complete the series. Into the details of the zoological results I am not competent to enter, but the greatest interest attaches to the fact that notwithstanding the pressure and absence of light, there is no depth limit to animal life.

As the Council of the Meteorological Office is nominated by the Council of the Royal Society, and as the Annual Report of the Office is submitted to the Royal Society, I think it right to mention a few points connected with the work of that department during the past year.

1. A method of recording the duration of bright sunshine by the charring of an object placed in the focus of a glass sphere, freely exposed to the rays of the sun, was devised by Mr. J. F. Campbell of Islay in 1856, and instruments, being modified forms of that originally proposed, have been employed for some time at Greenwich, at Kew, and at a few private observatories. Certain difficulties in adjusting the paper about to be charred to the path of the burning spot, which had hitherto prevented the adoption of Mr. Campbell's invention as a part of the ordinary equipment of a meteorological observing station, have been at last successfully overcome by an arrangement designed by Prof Stokes; and thirty stations in the British Isles have now been supplied with instruments of the pattern proposed by him We may thus hope to obtain in future a sufficient record of a meteorological element, which is of primary importance in its relations to agricul ure, and to the public health, but which has hitherto been very imperfectly registered

2 The climatology of the Arctic regions, in addition to its importance as a part of the general physics of the globe, possesses a special interest in connection with geographical exploration. As a contribution to our knowledge of this subject, the Meteorological Office has entrusted to Mr. R Strachan the task of bringing together, and discussing on an uniform plan, the results of the observations taken at intervals during the last sixty years, in the region extending from the meridian of 45° W to that of 120° W, and from the parallel of 60° to that of 80°, either at land stations or at the winter quarters of British and American expeditions A considerable portion of this discussion has been already published, the remainder may be expected in the course of next year.

3 Another publication of the Meteorological Office may be mentioned as serving to mark the advance in meteorological theory, which has been achieved during the last fifteen years The old "Barometer Manual and Weather Guide" of the Board of Trade has been replaced, so far as it relates to the weather of the British Isles, by a work entitled "Aids to the Study and Forecast of Weather," prepared under the direction of the Meteorological Office by the Rev W. Clement Ley Though some of the views put forward in the later work may, perhaps, be regarded as not sufficiently established by observation, yet a comparison of the two works cannot fail to leave upon the reader's mind the impression that in the interval between their respective dates of publication, some real progress has been made in meteorology. Perhaps this is most conspicuous in the enlarged ideas that are now entertained concerning the conditions upon which the changes of weather depend. Local weather was first discovered to be contingent upon travelling areas of disturbance, each of which averaged many hundreds of miles in diameter, while, at the present time, the relation of these areas to one another, as parts of a single terrestrial system, has become a prominent topic of inquiry. If meteorology has thus been, to a certain extent, rescued from the ever-accumulating choas of numerical tabulations, which threatened to engulf the whole science, the improvement is mainly due to the development in recent times of the synoptic study of weather over large regions of the earth's surface, to which so great an impetus has been given by the extended facilities of telegraphic communication.

4. Balloon ascents, with a view to military purposes, are now systematically carried on under the direction of the War Office; and the endeavour has been made to take advantage of these ascents for observations of the thickness of the aerial current which causes our winds, and of the peculiarities of the currents above it in the upper strata of the atmosphere The military authorities have offered their co-operation in the most cordial manner; but the attention of an aeronaut is often so much engrossed by the operations necessary for working his balloon, that he has but little leisure for taking systematic records Nevertheless, observations of considerable interest have already been obtained, relating especially to the velocity and direction of the upper air currents, and there can be no doubt that a continuance of such observations affords the best prospect at present open to us of adding to the very scanty knowledge which we possess of the movements of the atmosphere, even at a moderate height above the earth's surface.

Among the various duties which the President of the Royal Society is called upon to fulfil, there are those of a Trustee of the British Museum, and, as an operation of great importance to science, namely the removal of the natural history collections to the new building at South Kensington, is now going on, the Fellows may be interested to hear what progress has been made in the work

The plans for the new building were approved as long ago as April, 1868 but the works were not commenced until the early part of 1873. Their progress was retarded by difficulties in the supply of the terra cotta with which the building is faced within and without, and in which the mouldings of arches and other ornamental features are executed.

The building was finally handed over to the Trustees in the month of June of the present year It contains cases for three only of the departments for which it is intended, namely, Mineralogy, Geology, and Botany, the necessary funds for the Zoological Department not having yet been voted As the latter collections are equal in bulk to the other three collectively, it follows that only half the new building can at present be actually occupied. The removal of the collections for which cases had been provided, commenced in the last week of July, and was virtually completed by the end of September.

Geology, which was very inadequately displayed in the old building, is now more commodiously accommodated. It now occupies a gallery 280 feet in length by 52 in breadth, forming the ground floor of the east wing of the new museum, together with eight other galleries covering an area of 200 × 170 feet at the back, and admirably adapted for the exhibition of the specimens One of these galleries will be devoted to the illustration of stratification

The principal part of the Minerals has been moved and replaced in the cases in which they were arranged in the old building The collection now occupies the first floor of the east wing of the new museum, and the space devoted to it is 280 × 50 feet in area. It is already arranged for exhibition.

The Botanical collections are placed in the gallery over the minerals, where the space for exhibition and the conveniences for study are much greater than in their old quarters

The construction of the cases for the Zoological specimens, and the ultimate removal of these collections, must depend upon the amount of the Parliamentary vote for the purpose, but under the most favourable conditions it can hardly be hoped that this department can be open to the public or to students for two years from the present time

The "Index Museum," designed by Professor Owen, will form a prominent feature in the new museum The object of it, in his words, is "to show the type characters of the principal groups of organised beings," and "to convey to the great majority of visitors, who are not naturalists, as much information and general notions of its aim as the hall they will first enter and survey could be made to afford."

One of the principal difficulties attending the transfer of the Natural History Departments to a separate building consists in the provision of books for the use of the keepers and their staff, as well as for students who may visit the museum Hitherto the separate collections of books, known as departmental libraries, supplemented as occasion might require from the main library of the museum, have sufficed for all purposes. But now, when the departmental libraries have to stand by themselves, it is impracticable to carry on even the current work of arrangement without additional resources. For an adequate supply of the necessary works a very large outlay would be required, sup-

posing that the works were in the market. But many of them are out of print and have become scarce, and a large grant of public money would perhaps raise the market price almost in proportion to its magnitude. This being so, it has been thought best, on the whole, by the Government to make an annual grant to be expended from time to time as favourable opportunities for purchase may offer If it should prove possible, and on other grounds desirable, to allow the Banks' Library to follow the collections with which it has always been practically connected, the wants of the Natural History Departments would (so far as books up to the date of its bequeathment are concerned) be in a great measure supplied.

Another of the duties which falls officially on your President is to take part in the organisation of technical education as promoted by the City and Guilds of London Institute, which is now incorporated under the Companies Acts, 1862-80, as a registered association, and of which the Presidents of the Royal Society, the Chemical Society, the Institute of Civil Engineers, and the Chairman of the Council of the Society of Arts, are members. In the Memorandum and Articles of Association of the Institute, its objects are fully set forth. They may be summarised under the following heads:—

1. The establishment of a central technical institution for instruction in the application of science and art to productive industry.

2. The establishment of trade and technical schools in London and in the country.

3. The development of technical education by means of examinations held at the Central Institution, or at other places.

4. To assist by means of grants existing institutions in which technical education is being promoted.

5 To accept gifts, bequests, and endowments for the purposes of the Institute.

The Institute is supported by subscriptions from sixteen of the City Companies, of which the largest contributors are the Mercers, Drapers, Fishmongers, Goldsmiths, and Clothworkers.

The Institute has been in active operation not much more than a year, and during the last six months the work of the Institute has developed considerably in each of its several departments. These may be considered under the following heads:—

1 Technical Instruction.

2. Examinations in Technology.

3. Asssistance to other Institutions.

1. Since November last courses of lectures and laboratory instruction have been given in the temporary class-rooms of the Institute, at the Cowper Street Schools, under the direction of Prof Armstrong, F R S., and of Prof Ayrton The subjects of instruction have included Inorganic and Organic Chemistry, with special reference to their industrial applications, Fuel, Electro-depositions of Metals, and Photographic Chemistry; General Physics, Steam, Electrical Engineering, Electrical Instrument Making, Electric Lighting, Weighing Appliances, and Motor Machinery

During the term ending July last the number of tickets issued to students, most of whom belonged to the artisan class, exceeded three hundred A considerable accession of students is expected as soon as the building in Tabernacle Row, the plans of which are already settled, shall be erected. This building, which is estimated to cost £20,000*l*., will provide accommodation for schools of Technical Physics, Technical Chemistry and Applied Mechanics Many of the day students at these classes are pupils of the Cowper Street Schools, and it is expected that, by adapting the course of technical instruction to be given in the College to the wants of these boys, a very complete technical school for the children of artisans will have been established.

The evening lectures and laboratory instruction, which are more advanced and more special, are attended very largely by external students, for whom the present temporary accommodation is already too limited.

At Kensington, schools have been established in which practical instruction is given in various art subjects, such as Painting and Drawing, Modelling, Designing, and Wood Engraving. These schools are attended by both sexes, and are under the immediate direction of Mr. Sparkes The numbers in attendance last term were as follows:—

Wood Engraving . . .	8 Students,	3 Men,	5 Women.
Modelling	28 ,,	26 ,,	2 ,,
Drawing and Painting from Life	42 ,,	19 ,,	23 ,,
Designing	33 ,,	3 ,,	30 ,,

The Central Institution for instruction in the application of the higher branches of science to industrial pursuits is about to be erected on a plot of ground in Exhibition Road, granted by the Commissioners of 1851. The construction of this building, which, when completed, will cost 50,000*l*., has been entrusted to Mr. Alfred Waterhouse, who is now engaged in the preparation of plans.

2. In the year 1879, the examinations in Technology, which had been initiated by the Society of Arts, were transferred to this Institute. Various changes where introduced into the regulations New subjects were added, and in order to stimulate the teaching of Technology throughout the country, the principle of payment to teachers on the results of the examinations was adopted The encouragement thus afforded to teachers gave a great impetus to the formation of classes throughout the country in technological subjects. Last year the number of candidates for examination was 202, while at the recent examination, held in May, 816 candidates presented themselves, of whom 515 satisfied the Examiners During the last few months the number of classes throughout the country, in which technical instruction is being given, has considerably increased, and, judging from the returns already received, there is reason to believe that the number of candidates, who will present themselves for examination next May will be much greater than in either of the preceding years The new programme, which is just issued, contains a syllabus of each subject of examination, and every effort has been made, short of testing the candidates' practical skill, to make the examinations as efficient as possible. To obtain the Institute's full certificate, each candidate is required to give evidence of having obtained some preliminary scientific knowledge

3. In order to take advantage of efforts that are already being made to advance technical education, the Institute has given sums of money for specific objects to several institutions in which technical instruction is provided The schools, colleges, and other bodies which have received grants from this Institute, are University College and King's College, London, the School of Art, Wood Carving, and Mining Association of Devon and Cornwall, the Nottingham Trade and Science Schools, the Artisans' Institute, the Birkbeck Institute, the Lancashire and Cheshire Union, and the Horological Institute.

The Artisans' Institute gives practical instruction in several of the humbler crafts in which artisans are engaged, such as carpentry, zinc work, and plumbers' work; and corresponds, therefore, to some slight extent with the apprenticeship schools of the Continent, from which, however, it differs in many important particulars. A similar experiment is being tried at the Horological Institute, where, at the expense of the Guilds, classes have been organised, in which apprentices receive practical instruction in the various branches of the watch-making trade.

It is found that the demand for technical instruction in London and throughout the provinces is very great, and the efforts that have been so far made by the City and Guilds of London Institute have been received with considerable satisfaction by artisans and others engaged in industrial pursuits, and promise, when further extended, to be of the utmost service in the development of technical education in this country Turning now more particularly to the progress and the applications of science, I venture to make mention of a few topics which have come under my own observation.

(To be continued.)

OUR ASTRONOMICAL COLUMN

LUNAR ECLIPSES, 1880-84.—The total eclipse of the moon is only partly visible in this country, the middle occurring at 3h. 39m. Greenwich time, and the moon not rising until seven minutes later, the end of the total phase takes place at 4h. 24m., and the last contact with the earth's shadow at 5h. 33m In Australia the whole eclipse may be witnessed to advantage On December 5, 1881, there will occur an almost total eclipse (magnitude 0 97), again only partly visible here; the first contact with the shadow at 3h. 28m, and the moon rising at 3h 50m.; greatest phase at 5h. 8m In 1882 there will be no lunar eclipse. On October 16, 1883, a partial eclipse is barely visible here, first contact with the shadow at 5h. 59m. a.m, the moon setting at 6h 25m. The next favourably-circumstanced lunar eclipse, as regards observation in this country, will take place on the evening of October 4, 1884; first contact with shadow at 8h. 15m, beginning of total phase at 9h. 16m., middle of the eclipse

at 10h. 2m., ending of total phase at 10h. 48m, and last contact with shadow at 11h. 49m.

A PROBABLE VARIABLE STAR.—On November 25 Swift's comet was compared with the star No 4339 of Lalande, by Mr Talmage at Mr Barclay's Observatory, Leyton, the magnitude of the star being estimated 8, as it was also by Lalande. Argelander, in the *Durchmusterung*, gives it 6·4, and Heis made it a naked eye star (6·7), but erroneously identifies it with Lalande 4359 It escaped observation in the Bonn Zones, and may be worth occasional examination as likely to prove an addition to our variable star list

FAYE'S COMET.—In the *Berliner astronomisches Jahrbuch* for 1882, Prof. Axel Moller, of Lund, has given an ephemeris of Faye's comet extending to the end of March next. On comparing the theoretical intensity of light appended to the ephemeris with that corresponding to particular epochs in other appearances, it will be found that there is a probability of observing the comet for some weeks from this time without difficulty if the larger instruments be employed. Thus at the beginning of January the calculated degree of brightness is more than twice that appertaining to the dates when the comet was first and last observed with the Northumberland telescope at Cambridge, during the return of 1850 51, and the geocentric position is favourable for observation, a month later the intensity of light is still equal to that at the time of the first observation with the Copenhagen refractor in 1865, and even at the close of Prof Axel-Moller's ephemeris it is equal to that at the first and last Cambridge observations above alluded to, the comet's place, however, will then be drawing into the evening twilight We have already remarked that the magnitude of the planetary perturbations of the comet's motion during the revolution 1873-1881 is greater than in any other revolution since the comet's discovery in 1843, and the success which has again attended his prediction of its apparent track in the heavens must have excited the admiration of those who have any experience or knowledge of such investigations, and the immense amount of skilled application involved in them

SWIFT'S COMET.—The following elements depend upon Mr Chandler's observation on October 25, one at Strassburg on November 9, and a third at Mr J. G Barclay's Observatory, Leyton, on November 25 —

Perihelion passage 1880, November 8 3691 Greenwich M T

	° ′
Longitude of perihelion	42 15 2
,, ascending node	294 46 6
Inclination	7 21 3
Log perihelion distance	0 04188

Motion—direct

The close resemblance to the orbit of the third comet of 1869, it will be seen, is maintained. The elements give these positions for Greenwich midnight —

	R A	Decl	Log distance from Earth	Log distance from Sun	[illegible]

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

OXFORD.—No further regulations have been issued by the University Commissioners for the Professoriate. Opinion is much divided in the University itself as to the operation of the new rules. There have been several memorials to the Commissioners got up, some praying that no alterations be made, others approving the new Councils of the Faculties. There seems to be a general feeling against insisting on the professors examining their classes every term, and against making attendance at their lectures compulsory The Councils of Faculties are regarded by many with favour as a means of bringing the tutors and lecturers of the various colleges who are engaged in teaching the same branch of learning into closer relationship, and enabling them better to divide the work among them.

At Balliol College an extra scholarship on the Blakenbury Foundation has been awarded to Mr. A D Hall of Manchester Grammar School, for Natural Science.

A MEETING of the Convocation of Victoria University was held at Owens College, Manchester, on Friday, Dr Greenwood presiding. A resolution was received from the Associates of the College expressing their gratification at the creation of the University, and pledging themselves to perform their part in maintaining the welfare, dignity, and fame of the University, and promoting its objects Standing orders for the regulation of the proceedings of Convocation were adopted, and the Rev C. J Poynting was appointed clerk.

THE recently-presented budget of Prussia shows that, despite the financial straits of the kingdom, no considerations of economy are allowed to hamper the growth of its scientific and educational system First on the list come the nine universities with an allotment of 7,050,000 marks (352,500*l*.) Berlin receives the lion's share, 1,378,348 marks, an increase of about 37,000 marks on its last annual subvention. Bonn and Konigsberg each have 740,000 marks, Breslau 600,000, Kiel 404,000, Marburg and Halle each 430,000, Gottingen 201,000, and Greifswald 136,000 Of the above mentioned sum about 1,306,000 marks are appropriated for extraordinary expenses in connection with the construction of university buildings, and of this amount Berlin absorbs over one half, viz, 766,000 marks The other chief items in the Budget of Public Instruction are Gymnasia and Realschulen, 5,000,000 marks, primary schools, 14,500,000, orphanages, schools for the blind, deaf and dumb, &c, 300,000; technical schools, and for the general furtherance of science and art, 3,000,000 marks.

THE number of pupils of Lycées and Colleges in the French Republic is 87,000 (46,500 for Lycées and 40,500 for Colleges). Last year it was only 84,700 These establishments may be considered as analogous to the English grammar schools.

Rivista Scientifico-Industriale, October 31.—*Résumé* of solar observations at Palermo Observatory in the third quarter of 1880, by Prof Ricco.—Experimental researches on the action of light on transpiration of plants, by Dr. Comes —Dynamometric break with circulation of water, by Prof. Ricco

Journal de Physique, November —On the combination of phosphuretted hydrogen with hydrochloric acid, by M. Ogier.—An amplifying barometer, by M Debrun

SOCIETIES AND ACADEMIES

LONDON

Linnean Society, November 18.—Robt McLachlan, F.R S, in the chair.—Dr. Geo. E Dobson exhibited a remarkable parasitic worm from the intestine of *Megaderma frons*, from the Gold Coast It appears allied to *Pterygodermatites plagiostoma*, Wedl, from the Long eared Hedgehog, though on first hasty examination he (Dr Dobson) had been disposed to regard it as a new genus, *Metabdella* Dr. McDonald further drew attention to its peculiar anatomical structure and relationships Dr. Cobbold agreed to the importance of the observations as verifying previous discoveries, with addition of novel structural details He considered the worm as identical with the *Ophiostomum* of Rudolphi and Willemoes Suhm, with *Pterygodermatites* of Wedl, and with *Rictularia* of Froelich, and he regarded it as an aberrant member of the Ophiostomidæ, whereas Wedl thought it came nearest the Cheiracanthidea.—Dr Cobbold also exhibited specimens of *Distoma crassum*, Busk (previously in 1875 shown to the Society), from a Chinese missionary who, on return to China with his wife and daughter, were again all attacked by the parasite, and obliged to return to England.—A paper was read on a proliferous condition of *Verbascum nigrum*, by the Rev. G. Henslow. The upper part was very diffuse with leafy axes produced from the centres of the flowers, while the lower part had flowers with very large ovaries adherent within to arrested proliferous branches. These differences may be attributed to the general tendency of

the sap to run to the extremities and thus cause an excess of development above with simultaneous arrested condition below.—A paper on the classification of the Gasteropoda (part 2) was read by Dr. J. Dennis McDonald. In this communication the author gives further data in support of his mode of arranging the group dependent on anatomical characters.—"Novitates Capenses" was the title of a paper by Messrs. P. MacOwan and H. Bolus, in which, among other novelties described of South African plants, were *Ranunculus Baurii*, *Ericinella passerinoides*, *Orthosiphon ambiguens*, and *Herpolirion capensis*, the last a representative of a form hitherto known only from Australia.—A communication from the Rev. M. J. Berkeley, on Australian fungi (part 2), principally received from Baron F. von Muller, was taken as read.—Lieut. Col H. Godwin-Austin was elected a Fellow of the Society.

Entomological Society, November 3.—Sir Jno. Lubbock, Bart., vice-president, in the chair —Mr. E. Meyrick of Hungerford, Wilts, and Capt Thos. Broun of Auckland, New Zealand, were elected as Ordinary Members, and Dr. J. E. Brandt, president of the Russian Entomological Society, was elected as a Foreign Member of the Society.—Mr. Waterhouse exhibited, on behalf of Mr. Sydney Olliffe, a pair of dwarfed specimens of *Epione vespertaria*, taken at Arundel —Mr. McLachlan exhibited some curious galls on a broad-leaved *Eucalyptus* from Australia, which were stated to be made by a lepidopterous larva, and also mentioned that in a letter he had received from Mr. Rutherford, dated from Camaroons, West Africa, the writer stated that he had taken *Papilio merope* and *Papilio cenea* in copula. Mr. Trimen doubted that the butterfly referred to by Mr. Rutherford was *P. cenea*, Stoll, which, to the best of his knowledge, was a form of the female confined to South Africa, and was more probably either *Hippocoon*, Fab., or one of the other prevalent West African forms.—Prof. Westwood exhibited a globular gall on the surface of a sallow leaf made by a species of *Tenthredinidæ*, and also a dipterous larva (Syrphus) found closely adhering to the stem of a pelargonium —Mr Kirby exhibited a remarkable variety of *Epunda lutulenta*, and also a remarkable form of *Apatura*, stated to have been taken by Mr. Ralfe in Pinner Wood.—Sir Jno Lubbock exhibited some interesting larvæ which Mr. Culvert had forwarded to him from the Troad through Sir Joseph Hooker He stated that these larvæ had recently appeared there in great numbers, and were likely to prove most useful, as they fed on the eggs of locusts. These larvæ were probably coleopterous, and Sir Jno Lubbock suggested that if the species does not exist in Cyprus it might be worth while to introduce it there —Mr. Trimen exhibited a wingless female specimen of the Hymenoptera, which he had strong grounds for believing was the female of the well-known *Dorylus helvolus*, Linn —Mr Trimen also exhibited six cases fabricated by a South African lepidopterous larva, of which the outer covering consisted of particles of sand and fragments of stone, which gave them a most peculiar aspect, resembling in general appearance a myriapod.—Sir Sydney Saunders read a paper on the habits and affinities of the hymenopterous genus *Scleroderma*, with descriptions of new species —Mr Edward Saunders read a paper entitled a synopsis of British *Heterogyna* and fossorial *Hymenoptera*.—Prof. Westwood read a paper containing descriptions of new species of exotic diptera, with a supplement containing descriptions of species formerly described by the author in somewhat inaccessible publications.

PARIS

Academy of Sciences, November 15.—M. Edm. Becquerel in the chair.—Researches in isomerism, benzine, and dipropargyl, by MM Berthelot and Ogier.—On papaine; new contribution to the study of soluble ferments, by M. Wurtz In one experiment 0·05 gr of papaine fluidified about two thousand times its weight of moist fibrine. It seems that it begins by fixing on the fibrine, and the insoluble product gives, by action of water, soluble products of hydratation of fibrine, while the ferment, becoming free again, may act on a new portion of fibrine. The action is thus related to that of chemical agents, *e.g* sulphuric acid.—Enrichment of plumbic earths by a current of compressed air, by M. Delesse. The apparatus, called *trieur à soufflet*, effects a sorting of pulverulent matters, which cannot be separated by water. Earths of very fine grain cannot well be treated with it, and unfortunately it is they that contain most lead. The lead-dust produced is unhealthy for the workmen.—Observations of M de Quatrefages on the Marquis de Nadaillac's work, "Les premiers Hommes et les Temps préhistoriques." M. de Quatrefages thinks that man probably existed in Portugal in the Tertiary epoch.—Observations on the publication of Dr. Guérin's works, by M. de Quatrefages —On the arrangement of the cervical vertebræ in the Chelonians, by M. Vaillant.—Experimental researches on the heat of man during movement, by M. Bonnal. *Inter alia*, all muscular exercise raises the rectal temperature. The increase is not directly related either to duration of the exercise or to apparent fatigue. The altitude, state of the atmosphere, energy of movements, and nature of clothing affect the increase. All rapid exercise diminishes the peripheral temperature (in mouth, armpit, or groin) The rectal heat may reach 39 5°. In rapid climbing it is in the first half hour that the rectal temperature is most raised, it may then become stationary or fall In general, a rigorous application of the laws of mechanics to the human system is not warranted.—Studies on the habits of phylloxera during August to November 1880, by M. Fabre. The young insects showed (in the author's experiments) a strong liking for light. The present year seems very unfavourable to the parasite —On some linear differential equations, by M. Brioschi —On the equilibrium of flexible and inextensible surfaces, by M. Lecornu.—On the compressibility of oxygen and the action of this gas on mercury when put in contact with it, by M. Amagat. Oxygen and mercury (pure and dry) he found to remain indefinitely long in contact without absorption. He operated at 50° and 100°, and with pressures from 110 to 420 atm The compressibility of oxygen follows the laws he gave in his memoir of August 30. MM. Chevreul and Dumas made remarks on the subject —On the liquefaction of ozone in presence of carbonic acid, and on its colour in the liquid state, by MM Hautefeuille and Chappuis. Gradual compression of a mixture of ozonised oxygen and carbonic acid at − 23° gives a blue liquid of the same shade as the gas above. The products of decomposition of carbonic acid by the effluve are proved (by the blue colour on compressing) to contain a large proportion of ozone.—On malleable iron, by M Forquignon. It seems to be intermediate between steel and grey pig-iron, differing from the latter by the special nature of its amorphous graphite and its greater tenacity; from steel, by its small elongations and its large proportion of graphite.—On the presence of phosphorus in the rocks of Brittany, by M. Lechartier.—On the composition of petroleums of the Caucasus, by MM Schutzenberger and Ionine —On the temperatures of inflammation of gaseous mixtures, by MM Mallard and Le Chatelier. Among other results, mixtures of protocarburetted hydrogen not only enter into slow combustion, but, when submitted to a certain temperature, may be inflamed after a variable time (which is longer the lower the temperature).—On the secondary wave of muscle, by M. Richet A second contraction occurs, without fresh stimulation —On the contagion of boils, by M. Trastour —On the use of boring machines without use of explosive matter, by M Biver The advantages of Mr. Brunton's system are indicated.

THURSDAY, DECEMBER 9, 1880

BRITISH EARTHQUAKES

ON Sunday evening last week (28th Nov.) the northern parts of the British Isles were slightly shaken by an earthquake. The recent disastrous earthquake shocks in Croatia have called renewed attention to this still mysterious geological phenomenon, and now, while the subject is still fresh and under discussion, a milder visitation of the same nature reminds us that our islands are not wholly exempt from their share in the pulsations of the terrestrial crust. Save the vague and inexact newspaper paragraphs which chronicle the impressions of different observers, we have no information as to the direction of propagation of the earthquake wave of last week, its duration, relative intensity, and angle of emergence at different localities. It appears to have been one of the usual type of earth-tremors experienced in this country, and to have affected the region which, during the present century at least, has been most subject to such movements. It is reported as having been felt at many points in the central valley of Scotland and in the north-east of Ireland, also along the west coast as far north as the further end of the Long Island. Its effects appear to have been most marked over the area occupied by the crystalline schists. In Bute the house-bells rang. At Oban a portion of the plaster was detached from the ceiling of the parish church during the service of the Sunday-school. At Inverary also some plaster was loosened, and a sensation of nausea and giddiness is even said to have been experienced. At Blair Athole the oil in the table-lamps was thrown into undulations, which rose over half an inch up the side of the glass. Over the Lowland belt the effects were less perceptible, though they are alleged to have been distinctly felt as far as Edinburgh. By some observers the duration of the shock was estimated at two, by others at ten seconds. In some places the movement was thought to be from the north-west, in others, from the south-west. One of the phenomena duly chronicled in most of the narratives is the jingling and creaking made by crockery and furniture. Such is the usual meagre kind of detail out of which an explanation of the cause of earth quake movements in Britain is in truth hardly possible.

If we look back into the history of the subject numerous references to earthquake shocks will be found in the annals of the last seven or eight centuries in this country. And if the chroniclers are to be believed, some of these were of exceptional severity. According to the list compiled by Sir John Prestwich, shocks seem to have been specially numerous and severe in the twelfth century. Thus on the 2nd of August, 1134, England was shaken by an earthquake just at the very time that Henry I. was about to take ship for Normandy; "flames of fire burst forth with great violence out of certain riffs of the earth." On another occasion, in the same century, the bed of the Thames was laid bare at London. We read, too, of churches and other buildings having been from time to time thrown down, and of open rents having been left in the ground after the passage of the shock.

In the contemporary records of these phenomena the geologist vainly searches for particulars that may serve to elucidate their origin. He finds much that is doubtfully correct, not a little that is obviously fabulous. Naturally the events were considered merely in their relations to the human population of the country, and those aspects of them were noted that bore special interest in that respect. Most frequently they were regarded in the light of divine judgments, and were connected with some real or imputed delinquency on the part of the inhabitants. We read, for instance, that on the 8th November, 1608, a rather smart shock of earthquake passed over Scotland. In the southern counties it was looked upon as a result of "the extraordinar drouth in the summer and winter before." But the more orthodox worthies in the farther north took a higher view of it. The kirk-session of Aberdeen met, and accepting the earthquake as "a document that God is angry against this land and against this city in particular for the manifold sins of the people," appointed a solemn fast for next day. On further reflection they came to recognise one sin in particular as having doubtless called down the judgment. For more than 150 years, in virtue of a bull granted by Pope Nicolas V., the proprietors on the banks of the River Dee had been accustomed to fish salmon on Sunday. These Sabbath-breakers were accordingly now summoned before the session and rebuked. Some of them agreed to give up their custom, but "some plainly refusit anyway to forbear." Again on 20th October, 1580, an earthquake occurred that particularly affected the house of the Master of Gray. The boy king, James VI. asking Fergusson, the minister of Dunfermline, "What he thought it could mean, that that house alone should shake and totter," was grimly answered by the divine "Sir, why should not the devil rock his awn bairns?"

Doubtless many of the events chronicled in former centuries as earthquakes may not have been of that nature. Landslips and violent storms would account for some of the phenomena recorded. In looking over the lists of reputed earthquakes we cannot fail to notice that some districts of the country have been specially liable to the visitation. One of these has been the south-west of England, embracing the lower basin of the Severn with Somerset, Gloucester, Worcester, Cornwall, and the adjoining counties. Another notable area for a hundred years past has been the southern highlands of Perthshire.

After making every allowance for the vast multiplication of the means of recording passing events afforded by the extension of newspapers and the consequent increasing minuteness of detail in our domestic annals, there seems no reason to doubt that the number of earthquake shocks has increased during the present century, though possibly none may have reached the severity of some recorded in earlier periods. During the four years subsequent to September, 1839, upwards of 200 shocks were felt in Perthshire, some of which extended over nearly the whole of Scotland.

In searching for a possible solution of the problem presented by these terrestrial commotions one or two circumstances should be specially considered. In the great majority of cases where details of any kind have been preserved of the nature of the earthquakes, reference is made to noises that immediately preceded the actual

shock In not a few instances these seem to have been the most alarming part of the phenomena. They are variously likened to the sound of a rushing wind, the roll of waggons, the muttering of thunder, or the rattle of cannon With these aërial vibrations there are also recorded sounds as of a sudden snap or blow, or explosion in the earth underneath Another feature of the earthquake-register is the persistence with which a relation is believed to exist between the commotion in the ground and the state of the atmosphere above In some cases, indeed, the barometer is said to have suddenly fallen, and then to have risen after the shock had passed Warm, damp, moist weather, heavy rain, thunder, strange electrical discharges, fire-balls, and other meteoric phenomena are chronicled as the concomitants of earthquakes It may be said, of course, that the occurrence of these events together is only of the nature of a coincidence, and cannot conceivably be anything else There can be no doubt, however, that in Britain, as on the Continent, earthquakes have been more numerous in the winter than in the summer half of the year Of the fifty-nine earthquakes in Sir John Prestwich's list, as Prof Prestwich has pointed out, eleven occurred in winter, eleven in spring, seven in summer, and eight in autumn Out of 139 earthquakes recorded as having happened in Scotland up to September, 1839, eighty-nine occurred in the winter half of the year and fifty in the summer half We cannot suppose that any variation in the meteorological condition of the atmosphere can directly give rise to an earthquake Nevertheless it is conceivable that where the crust of the earth is in a condition of tension, rapid and extensive changes of atmospheric pressure may destroy an equilibrium that has previously been barely maintained The observed relation between a low barometer and the more copious escape of fire-damp within coal-mines may possibly be of wider application

It is evident, moreover, that the source of disturbance must be at no great depth from the surface This is shown by the markedly local character of the phenomena A shock of considerable violence which rends walls, overturns chimney-pots, rings bells, shakes furniture, and fills with alarm the inhabitants of a few parishes, but is quite unperceived in the districts around, cannot have a deep-seated origin. In looking at the districts specially liable to such visitations we notice in some degree a connection with geological structure The earthquake area in the south-west of England embraces within its borders the ranges of the Malvern and Mendip Hills, which, with the surrounding country, point to a long succession of geological disturbances, while the hot springs that still rise there furnish additional indications of a connection between the heated interior and the surface The most remarkable earthquake district in these islands at present is undoubtedly that of Comrie in Perthshire, where in the month of October, 1839, no fewer than sixty-six shocks were felt, the severest being perceived as far north as Dingwall, and as far south as Coldstream During the last forty years the British Association has appointed two Committees to investigate the nature of the shocks so frequently experienced there. But their labours cannot be said to have as yet thrown much light on the subject. They have erected seismometers of approved construction and sensitiveness, but in many cases shocks that have been distinctly perceptible to the inhabitants have not been registered by the instruments. Much speculation has been offered as to the cause that earth-tremors should be specially abundant in that district. Reference has been made by different observers to protrusions of granite and dykes of basalt which traverse the rocks, as if these igneous masses supplied a clue to the source of movement. But neither the granite bosses nor the dykes are specially conspicuous in the Comrie district On the contrary, they are there small in area and few in number compared with their occurrence in other tracts where earthquake shocks are rare A geological structure at Comrie, however, which so far as we are aware has not been dwelt upon in this connection, is the occurrence there of the great fracture by which the southern edge of the Scottish Highlands is bounded The Old Red Sandstone with its associated volcanic bands has been thrown on end against the crystalline schists Of the extent of the dislocation no precise measurements have yet been made; probably the amount of upthrow varies along the line At the north-eastern end of the fracture the sandstones and conglomerates have been placed on their ends for about two miles back from the fault. The line of dislocation can be traced across the island from sea to sea and across the island of Arran, whence it points for Ireland It is probably one of the largest, as it certainly is the longest, fracture within the British area On its north-western side lie the crumpled schists of the Highlands, on its south-eastern boundary are the dislocated, curved, and even inverted strata of the Old Red Sandstone. Two series of rocks of very different structure and elasticity are here brought abruptly together along a vertical or at least steeply inclined face, which must descend for several thousand feet from the surface So far therefore as geological structure can be supposed to govern the origin and effects of earthquakes there does not appear to be within these islands any line or district where terrestrial disturbances should be so readily felt as along the flanks of the Scottish Highlands Shocks coming from the Lowlands will recoil against the crystalline wall of the Highland schists, and be consequently more perceptible there than over the more homogeneous formations lying to the south Another area in which earthquakes have been frequently observed is that of the Great Glen This longest, straightest, and deepest of British valleys has from early geological times been a line of weakness

There seems every probability in the supposition that some at least of our earthquakes result from the sudden collapse of rocks that have been under great strain Their occurrence along lines of powerful fault suggests that the rocks on one or both sides of these dislocations are still subject to great tension, and that occasional relief is obtained by a snap which is powerful enough to generate an earthquake, though it gives rise to no change of level at the surface. When we reflect upon the constant strain on the terrestrial crust as it settles down upon the more rapidly contracting nucleus, we may be allowed to be grateful that earthquakes are not everywhere more numerous and destructive.

THE ENCYCLOPÆDIA BRITANNICA

The Encyclopædia Britannica. Ninth Edition Vols x and xi. (Edinburgh: A and C Black)

THESE two volumes of the *Encyclopædia Britannica* fully sustain the high character of the earlier volumes. The articles dealing with branches of physical and natural science are conspicuous by their high quality and number In geographical science this volume is particularly strong Dr. Rae contributes an article on "Greece," several specialists contribute the article on "Germany," and General Strachey of the Indian Civil Service has produced a very striking and valuable essay on the "Himalayas." Besides these there are shorter articles on "Greenland," "Grisons," "Guiana," the "Hawaiian Islands," and "Heligoland," all worthy of attention and replete with information. In medical science we note particularly the articles on "Gout," contributed by Dr Affleck, and on "Heart Diseases" by Dr. G. W Balfour In the department of natural history the articles are almost exclusively on subjects of a specific or technical character; Prof Newton writes on "Grouse," and Mr John Gibson on the "Hare" and the "Hippopotamus." Prof. Church contributes brief articles on "Hemp" and "Guano," and Dr. Trimen has a good descriptive paper on "Grasses." The article "Herbarium," contributed by Mr. E M Holmes, is a remarkably useful and practical handling of a subject on which most botanical writers have usually very little to say, and the summary of information as to the character of the principal herbaria in existence will be found acceptable for reference The contributions to the physical sciences are numerous and of great interest Dr Ball's article on "Gravitation" is at once simple and masterly. The article on "Harmonic Analysis" by the late Prof Clerk Maxwell is all too short, but admirable in its way Amongst technical subjects we may single out the articles on "Gunpowder" and "Gun-cotton" by Major Wardell and Prof Abel respectively, on "Heating" by Capt D. Galton, two long and very fully illustrated papers by Col. Maitland on "Gunmaking" and "Gunnery," and one on "Harbours" by Mr. T Stevenson, which is accompanied by several capital plates. Mr. J. Blyth contributes two valuable articles on the "Gyroscope" and on "Graduation." From the latter we miss one or two points that might well have been added. There is no account of the dividing-machine employed by Messrs Cooke and Sons of York in graduating the circles of the great Newall telescope, nor of the still more recent dividing engine constructed by the Waltham Watch Company The biographical articles are numerous and excellent. Those on the two "Herschels" are from the pen of Prof Pritchard. That on "Sir W Hamilton" is contributed by Miss E. Hamilton The biographical notice of "Sir W Rowan Hamilton" is by Prof. Tait, than whom no one is more competent to write of the great mathematician; though somehow we miss in this thoughtful and appreciative article the peculiar characteristics of Prof Tait's trenchant style We propose to notice at greater length the important articles on "Geometry," "Geology," and "Heat"

The editor did well, we think, when he intrusted the compilation of the article upon such an important subject as "Pure Geometry" to so accomplished a geometer as Prof. Henrici We can fancy what such an article would have been in the hands of the generality of English mathematicians trained at our conservative Universities, meek followers, for the most part, of one master "There is but one Geometry, and Euclid is its exponent." We ourselves entertain a very high regard for Euclid indeed our indebtedness to him for what ability we may have in geometrical science is as great as that of Cicero to Archias for eloquence, but we cannot help feeling that we might have had a far greater mastery over modern methods had our masters been acquainted with these methods themselves. "This book," says one who has recently left us, a consummate master of modern methods, "has been for nearly twenty-two centuries the encouragement and guide of scientific thought . The encouragement, for it contained a body of knowledge that was really known and could be relied on, and that, moreover, was growing in extent and application. . . the guide, for the aim of every scientific student of every subject was to bring his knowledge of that subject into a form as perfect as that which geometry had attained" In our author we have one who,

"Nullius addictus jurare in verba magistri,"

can ungrudgingly acknowledge the many good points of the old-world geometer, whilst, with keen-cutting scalpel, he boldly lays bare his numerous defects The present generation, perhaps, will not see Euclid superseded in our schools; but when his warmest defender makes him admit that his proofs might be abridged and improved, that alternative proofs may with advantage be appended to his, and that new problems and theorems might be interpolated, we may expect that a time will come, quickly if only the Universities would not handicap their favourite so heavily, when his order and numbering of propositions may be abolished, and his treatment of parallels shelved. In the meanwhile we must work in hope, and the article under notice will possibly pave the way for an improved mode of studying the science As is well known, Prof. Henrici has long been engaged in writing a Geometry to this work we must refer readers for his views on the subject. In the *book* we see him as the teacher, laying his foundations deep and strong and broad enough for the vast superstructure—all pure geometry—they have to bear in the *article*, he treats his subject at first rather as the historian and critic, though subsequently he takes up the *rôle* of teacher again ("use doth breed such a habit in a man"), and rapidly but most deftly sketches a beautiful outline—in parts filled in—of the "higher" geometry In a long, but far from tedious, sketch of sixty-four columns he treats pure geometry in two sections the first, in twenty-five and a half columns, gives an account of the Elementary, or Euclidian, Geometry the second is devoted to the Higher, or Projective, Geometry. In section I we have a running commentary on Euclid's text, which does at greater length, though somewhat in the same style, what De Morgan did some years since in the "Companion to the British Almanac" (1849) The axioms which lie at the basis of the subject are well discussed, and their foundation upon experience established it is pointed out that the connection between these axioms has only been shown "within the last twenty years

through the researches of Riemann and Helmholtz, although Grassmann had already published, in 1844, his classical but long-neglected 'Ausdehnungslehre.'" In this connexion we can merely refer to the admirable lecture by Clifford, "The Postulates of the Science of Space" There is a good statement of Euclid's assumptions, but we shall refer only to that which is made in I 4, thus enunciated by De Morgan "Any figure may be removed from place to place without alteration of form, and a plane figure may be turned round on the plane" This is employed by Prof Henrici, as it has been by many others, to prove I 5, with this difference, that he does it after Mr. Dodgson has made Euclid say there is "too much of the Irish Bull about it, and that it reminds one too vividly of the man who walked down his own throat, to deserve a place in a strictly philosophical treatise" But the difference between these two writers is a radical one, and is not confined to the above solitary instance. The treatment of Book I (the remarks on axiom xii. in connection with I. 28, 29 are valuable) calls for no special comment. In Book II. we have the propositions discussed symbolically and proved by the aid of laws investigated by Sir W Rowan Hamilton and Grassmann laws familiar to more advanced students, but which are here put in a manner within the grasp, we think, of junior students. The book is one, however, to which this class never take very kindly, and requires patience and illustration on the part of the teacher. We can, from the outline here given, guess how Prof. Henrici will treat this part of geometry in his forthcoming second volume. The remarks upon the Fourth Book conclude with a "few theorems not given by Euclid," but they are readily derived from (if not explicitly stated in) Euclid's constructions. Of Book V there is a careful sketch, and our author shows "Why the usual algebraical treatment of proportion is not really sound." (Here we may refer also to Mr A J Ellis's "Euclid's Conception of Ratio and Proportion" in his "Algebra identified with Geometry," and in a simpler form in a lecture at the College of Preceptors) Books VI., XI, XII need not delay us We come now to the Projective Geometry, which we should much like to see reproduced in pamphlet form for use in colleges or schools. We notice Prof. Henrici states, "In Euclid's *Elements* almost all] propositions refer to the *magnitude* of lines, angles, areas, or volumes, and therefore to measurement." This, too, is our own view, and we presume it is what Mr Wilson intended when he says "Every theorem may be shown to be a means of indirectly measuring some magnitude", whether it be so or not, at any rate Mr. Dodgson cannot impugn the Professor's more guarded statement Those properties of figures which do not alter by projection are projective properties: there is a slight omission in the illustrations given, an exception should, we think, have been made in the case when the plane of projection is perpendicular to the plane upon which the quadrilateral, or circle, or other figure is projected. The points of difference between the two sciences are well put. "In Euclid each proposition stands by itself; its connection with others is never indicated, the leading ideas contained in its proof are not stated; general principles do not exist. In the modern methods, on the other hand, the greatest importance is attached to the leading thoughts which pervade the whole; and general principles, which bring whole groups of theorems under one aspect, are given rather than separate propositions. The whole tendency is to generalisation" Euclid, it is open to remark, throughout his work, avoids the *infinite*, whereas the modern geometry, like a good Samaritan, takes the most tender care of it. The systems adopted by Prof Henrici are principally the methods of projection and correspondence—as handled by Von Staudt in the "Geometrie der Lage," and by Grassman in his above-cited work. We should like to analyse this sketch in detail, but we must forbear For curves of two dimensions it is quite too delicious for us to mar it by such scant and imperfect treatment as we could here give it, and we must content ourselves with giving the heads of the several sub-sections After the statement of definitions and preliminary explanations, we have segments of a line, projection and cross-ratios (Clifford's name for the anharmonic ratios of Chasles), correspondence, curves and cones of second order or second class, pole and polar, diameters and axes of conics, involution, involution determined by a conic on a line—foci, pencil of conics The conclusion of the essay on the conics is that we arrive at the definitions from which our English text-books usually start. So the mode of treatment will be seen to be novel to the majority of English students The concluding sections (six columns) on ruled quadric surfaces, but more especially on twisted cubics, seem to us to bear on their faces tokens of having been somewhat hurriedly written, so are not quite up to the high standard of the previous work At the close Prof Henrici refers his readers to Reye's "Geometrie der Lage" for "a more exhaustive treatment of the subject." "Scarcely any use has been made of algebra, and it would have been even possible to avoid this little, as is done by Reye." Prof. Clerk Maxwell, in a note to us, commended, in his own quaint way, this work of Reye A short list of references is appended.

We could have wished that the "Analytical Geometry" had also been intrusted to Prof Henrici, more especially that we might have seen how he would have connected the two together, and also that we might have had the subject discussed from a Continental point of view. We have sufficiently comprehensive and good treatises already by English writers, some of which are adorned with much of Prof. Cayley's work, and we feel, too, that had our author had *carte blanche* for space, he would have done his work well, whereas in attempting to pack much matter into a small space we think he has assumed much which is not familiar to some, and yet at the same time which is elementary to others who are advanced students. Nor does the article, to our mind, thoroughly serve for purposes of reference, though, no doubt, it goes some way to this end. The secret may be that "Pure Geometry" is more limited in its range, has, on one side, to do with a book known to almost all, and, on the other side, even does not reach, for the generality, beyond the conic sections; "Analytical Geometry," on the other hand, has to do with everything that relates to curves and surfaces, of whatever sort they may be. Prof. Cayley takes the line of analytical geometry "as a method," and confines himself, in his twenty-four and a half columns, to the consideration of the applications of Cartesian co-ordinates

almost exclusively. The article is divided into the two sections of plane and solid geometry. At the commencement the student is recommended by the weight of Prof. Cayley's advice to trace a number of curves, and he draws a few simple ones, so drawing attention to a point upon which Mr. Frost, in his "Curve-Tracing," strongly insists. Prof. Clifford, too, we believe, had it in his mind to publish an account of some methods which "are exceedingly simple and easy of application; they partake more of the nature of a manual craft than of a purely intellectual occupation, and may so be used as a rest from severer studies; and, as we can only imagine things of which we have seen the like by appealing directly to the senses, they extend those powers of concrete realisation which the growing complication of modern analysis renders daily more desirable." The methods he alluded to are "Projection, a process by which no alteration is made in the order, the class, nor in any other purely descriptive property of a curve;" then "those modifications of form which leave the *order* of a curve unaltered;" then "those changes which exercise no effect upon the class." In the last two cases he proposed to use a process which he used to call "the *composition of curves*, by which a curve of any order or class may be built up out of the simplest elements" We fear that we have lost this proposed sketch, with the many other sketches he had outlined and lived not long enough to endue with a vitality he could so well have given them After the illustrations referred to Prof Cayley discusses shortly the metrical theory, and obtains the several familiar equations both in plane and solid geometry. In short paragraphs polar, trilinear, point, and line co-ordinates are described, but not applied. We have noted scarcely any misprints in the first article, but in the second there are several, all of which are easily detected. The figures are very well done.

We would draw attention to the article on Geodesy by Col Clarke, which we have read with much pleasure It is well illustrated, and the eighteen columns treat of the following matters.—Horizontal angles, astronomical observations, calculation of triangulation, irregularities of the earth's surface, altitudes, longitude These are as fully discussed as need be in a sketch of the subject, and we shall expect that Col. Clarke's more extended work on Geodesy, referred to in NATURE, vol. xxi. p 423, will take its place as a standard work for some time to come.

Geology occupies at the present day so important a position in the circle of the sciences that it deserves to be treated, in any modern cyclopædia, with no niggard hand. A slender essay, confined to a survey of the broad features of geology, would have been sadly disappointing in such a work as the "Encyclopædia Britannica." It is therefore satisfactory to observe that Prof. Geikie, to whom the editor entrusted this article, has put a liberal interpretation upon his trust. He has treated his subject with a fulness worthy of a great and growing science, and worthy too of the noble plan upon which the Encyclopædia has been projected. The masterly article which he has contributed to the new edition] stretches over more than 320 columns, and is thus longer than most of the kindred articles, such as those on "Astronomy" and "Chemistry." Possibly it might have borne, here and there, a little condensation, but on the whole it is admirably fitted for its place. It stands forth as a solid and comprehensive monograph which, if reprinted from the Cyclopædia, would form one of the most substantial treatises in our geological literature. But the article is not only substantial, it is, like all Prof. Geikie's writings, eminently readable. The cardina virtues of an encyclopædist are accuracy and conciseness of expression, and he usually finds but little scope for the play of literary graces. Prof. Geikie, however, is far too polished an author to write upon any subject in an unattractive style, and the present article is sufficient to prove—were proof needed—that his graceful pen does not fail him, even when discoursing on the knottiest point in geology. The comprehensive nature of this article, and the originality with which the subject is treated, may be best shown by explaining the seven-fold division adopted by the author. First he deals with the *Cosmical Aspects of Geology*, and not only discusses the shape and the motions of the earth, but stretches his survey to the probable history of the solar system. Then he inquires into the nature of the materials of the earth's substance—an inquiry which falls under the head of *Geognosy*. In the early part of the article the author may seem to trench a little upon subjects which are treated in other articles, but this is almost inevitable in any cyclopædia It is not to be expected that the several essays shall just touch each other without overlap, like the pieces of a neatly-jointed mosaic. The geognostic division of the article is followed by a section on *Dynamical Geology*, and this in turn by one on *Structural Geology*, or the architecture of the earth. Under the head of *Palæontological Geology* Prof Geikie sketches the history of life as revealed by the fossiliferous deposits, while in the following section on *Stratigraphical Geology* he traces the chronological succession of events in the history of the stratified rocks Finally a chapter is devoted to *Physiographical Geology*, or a discussion of the origin of the physical features of the earth's surface.

To see for the first time a great actor play the part of a familiar character is a treat, but the pleasure is seldom quite free from a mixture of disappointment His reading of the part is usually not our pet and peculiar one, and we are, as it were, bullied into contentment by the great power of the performer We felt something akin to it when we read the article "Heat" by Sir William Thomson, though the feeling was of course unreasonable. It often happens when for the second time we see a great actor play a great part we yield ourselves to his charm without a trace of intellectual reserve, so it will most likely be when next we read the article "Heat" At all events, the readers of NATURE may be assured that there is little in this article that they can justly find fault with, whatever they may miss to find that they expected Could it be otherwise, when the author is the pupil of Regnault, the colleague of Joule, one of the patriarchs of the modern science of thermodynamics, the greatest living authority on the theory of heat in Britain? We shall therefore most modestly discharge our function by pointing out to our readers what they will find in Sir William Thomson's article, and by slightly indicating some points on which, to our regret, he has withheld his opinion

The article opens with a discussion of the sense of heat, and of the distinction between heat and temperature We are thus introduced to the conception of latent heat, which is explained at some length. The two leading methods of calorimetry, viz. calorimetry by latent heat, and thermometric calorimetry, are then discussed in general terms, and the results of the comparison of the different calorimetric units by Regnault and others are given. Then follows a full account of the origin of the modern theory of heat, which regards it as energy, and measures it by the equivalent amount of work We thus have a third method of calorimetry, which is called dynamical calorimetry Of the thirty-five pages occupied by the whole article eighteen are devoted to thermometry. This is the most important, and certainly the most interesting part of the article. After discussing a theoretical (and to some extent practical) system of thermometry by mixtures of hot and cold water, the thermoscope being the sense of heat in the hand, the author gives an elaborate classification of the different possible kinds of thermoscopes Then comes an extremely interesting discussion of the merits of the different kinds of thermometers with arbitrary scales The defects of the mercury-in-glass thermometer, and the advantages which led Regnault to prefer the (constant volume) air-thermometer are fully explained We do not remember to have anywhere seen so full, and, it is needless to say, so philosophical an account of Regnault's results of the comparison of the different thermometric scales The rest of the part devoted to thermometry is more or less speculative The absolute thermodynamic scale of temperature, invented by the author himself, is defined, and its great advantage pointed out, viz., that it gives us a definition of temperature " such that, if a thermometer were graduated according to it from observation of one class of thermal effects in any one particular substance, it would agree with a thermometer graduated according to the same thermodynamic law from the same class of effects in any other substance "

Thermodynamic formulæ are investigated in a variety of cases for graduating thermometers, according to the absolute scale, from experimental data concerning the thermometric substance. A number of instruments are described in detail which are intended to realise these cases in practice We are thus introduced to the water steam, mercury steam, and sulphurous acid steam thermometers, and the constant pressure hydrogen thermometer These instruments are mostly new as to their details, and all of them are new in the sense that they have not been practically used hitherto Nevertheless a great future is predicted for them It would appear that Sir William Thomson has himself constructed models of them all; but whether he has used any of them in practical work he does not say It has doubtless occurred to many of our readers, as it has to us, to have doubts and difficulties about thermometric measurements Nowhere could we find better reasons for our scepticism than in the earlier part of Sir William Thomson's discussion of the systems of thermometry at present in use, we shall look, therefore, with all the greater interest for some farther account of the practical working of these new instruments. Their success, were it even but partial, would be an immense gain to thermal science. Thermal capacity and specific heat are next defined; and a brief account of the leading features of the results of different experimenters is given, without detail as to the methods employed in obtaining them. For further information we are referred to the articles on "Thermodynamics," "Matter," "Liquid," "Steam." The remaining five pages of the article deal with the transference of heat. Radiation is explained and distinguished from other modes of transference; but to our great regret is dismissed very briefly A criticism of the work of the various experimenters in this department from an authority like Sir William Thomson would have been most interesting There is still much doubt and difficulty hanging over the subject of the diathermancy of gases, for instance, we need scarcely mention as an illustration the famous controversy which has raged over water vapour It may be however that these and kindred matters are to be treated under "Radiation" or "Light"; although we are not referred to these articles The general principles of the theory of the conduction or diffusion of heat, as laid down by Fourier, are explained, and a most interesting critical account is given of the earlier attempts to measure conductivity The explanation of the causes of the failure of Clément and Péclet in measuring high conductivities, such as that of copper, is very instructive, and should be closely studied by those engaged in like researches. Of the methods in use for measuring the thermal conductivity (or diffusivity as the case may be) of solids, Sir William Thomson prefers that of Angstrom, and recommends along with it the use of thermoelectric methods for determining the temperatures along the experimental bar. The mathematical theory of this method is given, and its connection with the researches of Forbes and Thomson on underground temperatures pointed out The method of Forbes for measuring the conductivities of metals in absolute measure is described in general terms, and the results obtained with it by Tait are given, and compared with those of Ångstrom and Thalèn. We regret that no mention is made of the recent attempts to measure the conductivities of liquids and gases The only result given is that of Bottomley for water, and no description of the method accompanies it It is quite true that the success of many of these attempts has been somewhat doubtful, but, for that very reason, a criticism of the methods by a competent and impartial authority would have been most opportune, and useful as a guide to future experimenters. Appended to the article are a series of ten tables of thermal constants, and a reasoned synopsis of the principal mathematical formulæ that occur in the theory of diffusion. This last is a most valuable part of the article, for it could be given only by a master of the subject, and it is likely to be extremely useful to many physicists, who have sufficient knowledge to enable them to use such formulæ, but not sufficient mathematical power to find them for themselves, or sufficient time to hunt them up from ponderous treatises and half-forgotten memoirs when they want them.

We sincerely congratulate the editor and publishers of the *Encyclopædia* on the high degree of success which continues to attend their great undertaking.

OUR BOOK SHELF

Life and Her Children: Glimpses of Animal Life from the Amœba to the Insects. By Arabella B. Buckley (London: Edward Stanford, 1880.)

AFTER light came life, and with that life there came its two great functions—growth and development. With the simplest as with the most complex forms there is the same eager race to be run, to increase in size, to multiply, and thus replenishing this earth, to die "Life and Her Children" is a praiseworthy and admirable attempt to tell us something of the Children that Life sends forth, and of their history Its main object is to acquaint young people with the structure and habits of the lower forms of life, but in our deliberate judgment it will do a great deal more. None will read its introductory chapter without advantage, and few will read the volume through without enjoyment Within its narrow limits of 300 small pages no candid reader would expect to find all the details that might be wished for, or all the illustrations that might be desired What constitutes the book's chief charm is the marvellously simple yet quite scientific style which runs through it, the food for thought and future study which it affords, and the truly philosophic glow which lights up its every page The volume gives a general account of Life's Simplest Children, the Protozoa The word "slime" does not seem to us quite a happy term by which to designate the living protoplasm of these creatures; this word conveys the idea of a something adhesive or glutinous, or of a something thrown off a living organism—a something without a structure (sordies, eluvies)—and there seems somewhat of a "contempt for nature," a thought certainly never present in the author's mind, in the use of such a word Jelly would seem a more appropriate word, as conveying the idea of the consistency requisite for life, and would have the sanction of use. Thus the Noctilucæ, called in this volume "tiny bags of slime," were described, if we mistake not, by their discoverer as "tiny spherical gelatinous bodies," and Prof. Huxley says, "Noctiluca may be described as 'a gelatinous transparent body about the one-sixtieth of an inch in diameter'"

The chapter on "How Star-fish Walk and Sea-Urchins Grow" is excellent The story of how the five curious little oval jelly bodies swimming about by their jelly lashes in the depths of the smooth water in some English bay—ended in becoming respectively a lily star, a brittle star, a starfish, a sea-urchin, and a sea-cucumber, is well told, and woodcuts, though they make one see as in a glass darkly, help in their own way to make the meaning plain In the "Outcasts of Animal Life" a difficult problem is treated of It need not surprise one that it is not solved The last four chapters tell of "the Snare-Weavers and their Hunting Relations (spiders)", the Insects which change their coats but not their bodies, and those which remodel their bodies within cover of their coats, "the Intelligent Insects with Helpless Children, as illustrated by the Ants." This volume thus tells of the greater part of the living invertebrate animals as they are spread over the earth to fight the battle of life. "Though in many places the battle is fierce and each one must fight remorselessly for himself and his little ones, yet the struggle consists chiefly in all the members of the various brigades doing their work in life to the best of their power, so that all while they live may lead a healthy, active existence. The little bird is fighting his battle when he builds his nest and seeks food for his mate and his little ones, and though in doing this he must kill the worm, and may perhaps by and by fall a victim himself to the hungry hawk, yet the worm heeds nothing of its danger till its life comes to an end, and the bird trills his merry song after his breakfast, and enjoys his life without thinking of perils to come. So Life sends her Children forth, and it remains for us to learn something of their history. If we could but know it all, and the thousands of different ways in which the beings around us struggle and live, we should be overwhelmed with wonder Even as it is, we may perhaps hope to gain such a glimpse of the labours of this great multitude as may lead us to wish to fight our own battle bravely and to work and strive and bear patiently, if only that we may be worthy to stand at the head of the vast family of Life's Children."

The work forms a charming introduction to the study of zoology—the science of living things—which we trust will find its way into many hands E P W

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications*]

The Editor urgently requests correspondents to keep their letters as short as possible. The pressure on his space is so great that it is impossible otherwise to ensure the appearance even of communications containing interesting and novel facts]

Prof. Tait and Mr. H. Spencer

As Mr. Spencer has already got the length of calling some of my statements "fictions, pure and absolute," it is time that this discussion should cease. But it is necessary that I should at least show my reasons for having made the statements in question. They will be found ample

Mr. Spencer's pamphlet, which originated this discussion, and in which I am the first subject brought up for vivisection, bears on the title-page that it deals with *Criticisms*.

The only passages of mine which Mr Spencer quotes, which can possibly have the slightest reference to himself, and which can in any way be construed into criticisms, are but two in number. In these, or in one of them, the cause of his attack on me must be sought

The first is mainly a verbal transcription from Mr Kirkman, and as such it is none of mine; but in introducing it I inadvertently (though correctly) spoke of the "Formula of Evolution" as a *definition*.

The second is a passage *from a different part* of my article on Sir E. Beckett's book, and its application is to materialists and agnostics in general.

This latter passage did not appear to me capable of having roused the vivisection-instincts of so calm a philosopher as Mr. Spencer, especially as it was not applied to any one in particular. Of course, then, I at once assumed that the former passage contained the offence which was to be expiated, and I was confirmed in this idea by the way in which Mr. Spencer put his *formula* alongside of the Law of Gravitation. I could not have ventured to suppose that Mr. Spencer "*did not even know that he was in the habit of saying formula rather than definition.*" This *naive* confession cannot but be correct. Had it been made in Mr. Spencer's pamphlet, I should not have thought it necessary to say a word. It explains at once his frequent entire misapprehensions of my meaning So I give up my plausible theory of the origin of Mr. Spencer's attack on me, and shall, henceforth, ascribe that attack to my having made a singularly apt and telling quotation from Shakespeare!

With regard to the other parts of the discussion, I feel that I need not add anything to what I have already said; except on one point, an important one.

Mr. Spencer has employed an old remark of Prof. Huxley as to what mathematics can, and cannot, do, but he has not employed it happily, for the question at issue is really this —Is it correct to speak, at one time, of force as an agent which changes a body's state of rest or of motion, and again to speak of it as the time-rate at which momentum changes or as the space-rate at which energy is transformed?

I answer that there is not the slightest inconvenience here, except, perhaps, in the eyes of those metaphysicians (if there be any) who fancy they know *what* force *is*. Such phrases as "the wind blows," or "the sun rises," though used by the most accurate even of scientific writers, would otherwise (on account of their anthropomorphism) have to be regarded as absolute nonsense. P. G. TAIT

Geological Climates

It was with great surprise I read Prof. Haughton's unqualified statement in last week's NATURE, that—"It is *impossible* to suggest any rearrangement of land and water which shall sensibly *raise the temperature of the West of Europe*,"—since I had, as I thought, in my recently-published volume—"Island Life"—not only "suggested" such a rearrangement, but also adduced much evidence to show that it had actually occurred throughout the periods when both the West of Europe and the Arctic regions enjoyed a much higher temperature than they do now. I will now briefly re-state my "suggestion," and will also make a few remarks on the general causes of difference of temperature, which may serve to render the subject more intelligible.

It is now well known that places in the temperate zones owe their temperature at different seasons only partially to the amount of direct sun-heat they receive, but very largely to the amounts of heat brought to them by currents of air. Thus we explain, not only the mild winter climate of our islands as due to the prevalence of westerly and south-westerly winds which have become warmed by passing over the Atlantic, but also the wonderful inequality of temperature at different seasons of the year. When we have warm spring like days in mid-winter, it is because these warm currents of air are passing steadily over our islands; while continued hard frosts are as clearly due to masses of cold air from the north or north-east which drift down to us, often with no perceptible wind. Again, when in April and May we have days as cold as those of December and January, they can always be traced to northerly or easterly currents of air, and are probably often connected with the southern drift of the icebergs at that season. It is clear then, that if south-westerly winds were to continue throughout the winter, the severity of that season would be entirely abolished, and the same effect would be produced if by any means the winds from the north and east lost their severity.

Now the source of the constant warmth of our westerly winds is admitted to be the influx of warm water into the North Atlantic—chiefly by the Gulf Stream, and this warm northward flow of tropical water, being primarily due to the trade-winds, is not confined to the Atlantic, but is equally present in the other great oceans, and similar effects are produced in them, though nowhere to so great a degree as in our islands, owing to our insular position and the great extent to which Europe to the east of us is permeated by water as compared with North America or Asia. The North Pacific, with its great Japan current, is probably quite as warm as the North Atlantic; but Vancouver's Island, though further south than London, has not so mild a climate; and this can be clearly traced to the great mass of land to the east and north of it, the lofty snow-clad mountains, and the absence of those deep gulfs and inland seas which do so much to ameliorate the climate of Europe.

Prof. Haughton states, in his "Lectures on Physical Geography," that the Kuro Siwo, or great Pacific current, is two and a half times as large as the Gulf Stream, while the Mozambique current, which forms the outflow of the warm waters of the Indian Ocean, is one and a half times as much, so that these two currents have together four times the bulk and heating power of the Gulf Stream. If therefore these two currents at any time obtained an entrance into the Arctic Ocean, it is difficult to over-estimate their effect on its climate. The Gulf Stream, of which probably not half passes northwards of our islands, gives to Iceland the same winter temperature as Philadelphia, and keeps the North Cape (far within the Arctic circle) permanently free from ice, and this, notwithstanding the powerful counteracting influences of the lofty Scandinavian mountains on the one side, and the huge ice-clad plateau of Greenland on the other. Suppose that only an equal proportion of the Kuro Siwo entered the Arctic Ocean, is it not probable that no sea-ice at all would form there? While, if Greenland were less elevated and thus ceased to be an accumulator of ice, the combined effect might be to render the whole Polar area free of icebergs. This would at once do away with the chief source of winter cold to all north temperate lands, and ameliorate the climate of America as much, proportionately, as that of Europe.

But we have yet to consider a still more powerful agent in ameliorating the climate of Western Europe in Secondary and early Tertiary times. The heated waters of the Indian Ocean have now no northern outlet, and only penetrate the continent in the sub-tropical Red Sea and Persian Gulf. Now if we suppose the waters of the Bay of Bengal and the Arabian Sea to have had northward outlets through the heart of the Euro-Asiatic continent, penetrating in two or more directions into the then much more extensive Arctic Ocean, we should have an agency at work which would render the presence of any permanent ice in the North Polar area as impossible as it is now in Scotland. The cooling agency of ice being once abolished, the comparatively small area of the Polar as compared with the Tropical seas (about one-tenth) would facilitate the raising of the temperature of the former to perhaps 15° or 20° F. above the freezing point, and this would not only give the Arctic lowlands a climate quite sufficient for the vegetation which we know they supported, but, by doing away with the only source of our winter cold, would give our islands a perfect immunity from frosts and render them capable of supporting the vegetation now characteristic of sub-tropical lands.

That the modifications of land and sea here indicated *did* exist throughout a considerable portion of past geological ages, and that the existing consolidation of the great northern continents, to which the possibility of our present Arctic climates is mainly due, is a comparatively recent and abnormal phenomenon, I have endeavoured to prove in the work already referred to. At present I have only undertaken to show, that a "suggested" rearrangement of land and water adequate to raise the temperature of Western Europe to a very sensible, or even to a very large extent, *is* "possible." ALFRED R. WALLACE

Photophonic Music

I HAVE not yet met with any reference to the capabilities of the photophone for giving musical harmonies. Might not some curious effects be got in some such way as this:—Suppose a disk perforated with holes in four concentric circles corresponding to the notes of a chord; a beam of light to be sent through each circle to a lens and disk of rubber with tube (as Prof. Bell has described), the four tubes debouching in a cup-shaped cavity to be applied to the ear, lastly, the disk to be rotated variably by means of a small windmill or otherwise. Another arrangement might be to make the beams of light pass through the holes to selenium cells in four telephone circuits, the four telephones being placed in one frame, against which the listener's ear would be put, or coupled in pairs, one pair put to either ear. Again, might not harmonised tunes be obtained thus:—Suppose a broad open drum of wood or cardboard rotated uniformly on a screw forming a vertical axis. The drum is perforated in a spiral band of four lines of holes (for the light), corresponding to the notes of the harmonised air to be produced. This spiral band passes before four rubber disks or selenium cells (as in the former system), but arranged vertically and placed within the drum, at the lower part. The drum, it will be understood, works gradually down the axis, presenting a continuous four-line series of holes before the receiving apparatus. Again, a long continuous strip of cardboard, with four rows of holes, might be passed before the receiver in any convenient way. M.

The "Philosophy of Language"

THOUGH it is my principle never to answer any criticism of my writings, I find myself obliged to deviate for once from this rule by the character of your highly esteemed review, and by the desire to find a discerning appreciation from your readers, whose judgment has for me the greater value, as it is the main aim of all my works to restore the relations between the science of mind and natural philosophy. Therefore you would oblige me very much by publishing the following short remarks:—

The critic of my *brochure* ("Max Muller and the Philosophy of Language,") says, ". . . Nor is speech the deliberate product of a conscious will." Now it is the real aim of all my works on the philosophy of language to show how the human will—before dark and unconscious—grows to consciousness *by language* and human activity intimately connected with it. Can there be the least doubt of this, even if I refer only to the motto of my "Origin of Language,"—"Language has created reason, before language man was without reason"?

Your critic has made me say *just the contrary of what I really have said*. Besides, it would have been only fair if the critic had pointed to the following little passage of my *brochure*:—

"Max Muller has since expressed *his full assent* to this view," (viz., my theory of the origin of language).

Mayence, November 11 LUDWIG NOIRÉ

[I gladly accept the author's assurance that he adheres to the view that "language has created reason." At the same time his

express words as well as the general bent of his argument seemed to point in the opposite direction. Thus at p. 81 he writes:—"Language is a product of *association*. . . . Language is a product of an active, not of a passive, process, it is the child of *will*, not of sensation." The statement that language is "the child of will" seems to me practically identical with the assertion that "speech is the deliberate product of a conscious will," because the will here spoken of, being "an active process," is necessarily conscious.—A. H. KEANE.]

Notes on the Mode of Flight of the Albatross

WHEN watching the albatross one is struck with the fact that the bird gets up to windward without appearing to use his wings to a degree sufficient to account for the same. The sailors are satisfied with the explanation that he beats to windward. The conditions are of course not analogous to those of a ship sailing to windward. If the wind be very light, or if there be a calm, occasional powerful and obvious flapping of the wings occurs If there is no wind, the birds often settle on the water round the ship. In very heavy weather the birds disappear altogether, probably settling on the water. Except that for breeding they resort to the islands, I believe they frequent the open ocean, where the surface is seldom without more or less swell.

On watching the flight of the albatross, one observes that in order to rise from the water violent and obvious flapping of the wings is necessary, which is continued some time after the wings cease to strike the water. After a start has thus been effected, if there is a fresh breeze, the wings are kept almost motionless. Sometimes the bird goes some distance with the impetus derived from the flapping of the wings at the start, but sooner or later he turns so as to expose the plane surface of his wings full to the force of the wind, rising at the same time some height above the water, and drifts off to leeward, thus soon acquiring the velocity of the wind, then swooping down into the hollow between two swells, he turns his head to windward, and keeping close to the surface of the water, sails along more or less against the wind for a surprising distance; finally, rising over the crest of a wave comparatively high into the air, and turning with his wings as before, so as to catch the wind to the fullest extent, he again lets himself drift off to leeward

Thus the manœuvre he performs seems to consist in drifting with the wind in such a way as to attain its velocity very soon, and then turning round so as to make use of this velocity to carry him in the contrary direction

Of course if he still remained exposed to the wind which had imparted to him its velocity he would not travel far against it before he came to a standstill, and he would certainly make no progress to windward, but by keeping close to the surface of the water, and as much as possible in the hollows between the waves, he is almost out of the wind, and in this comparatively calm region the impetus derived from the wind will carry him a long distance in exactly the opposite direction to that of the wind itself

This manœuvre appears to be an important factor No doubt the almost imperceptible movement of the wings may assist, though that this alone is insufficient to account for the progress to windward appears evident from the powerful efforts made with the wings in rising from the water and in calm weather I have never had an opportunity to observe the albatross flying over land or over level water. If the manœuvre above described be an important factor, the birds then would have to use their wings much as they do in very light winds on the ocean If very strong winds were blowing, they would have to settle on the land or in the water in order to remain at the locality ARTHUR W BATEMAN

A General Theorem in Kinematics

PROF. EVERETT (*ante*, p. 99) has overlooked in the introductory paragraphs of Prof. Schell's paper, to which he refers for the original statement of the theorem re-discovered by Prof. Minchin, the acknowledgment: "Der Mittelpunkt der Beschleunigungen und jene beiden Kreise wurden bereits 1853 von BRESSE gefunden." The reference is to the *Journal de l'École Polytechnique*, tom. xx, "Mémoire sur un Théorème nouveau concernant les Mouvements Plans, etc" By means of the "two circles" Bresse determines the point *c* (*J*) "qui aura une accélération totale nulle" (p. 82), and then by very ingenious application of kinematic principles deduces those relations to it which any arbitrary point (*P*) has, as given by Prof Minchin. Bresse names *c* "second centre instantané de rotation."

University Hall, December 4 J. J. WALKER

Geometrical Optics

YOUR correspondent "P. C." (NATURE, vol. xxii. p 607) asks information concerning a work, in English or French, on geometrical optics, thoroughly explaining the optical construction of telescopes and microscopes. I am not aware of any such publication these last forty years, but deem it possible that it may interest your correspondent to know of the existence of such a work in German by von Littrow, entitled "Dioptrik, oder Anleitung zur Verfertigung der Fernrohre" It was published, I believe, in Vienna about 1838. W. G. LOGEMAN

High Burghal School, Haarlem, Holland, November 17

[Littrow's "Dioptrik" was published at Vienna in 1830 in 8vo —ED]

Ozone

IF a slip of the prepared paper, used for testing for atmospheric ozone, be carefully moistened on one side with alcohol, using a clean camel hair brush, on burning off the spirit and immersing the slip of paper in water the paper changes to a deep purple colour, as deep as No 8 in Negretti and Zambra's scale of colours for ozone.

Is this due to the development of ozone? as, according to Schonbein, heat destroys ozone. J. P.

Leicester, December 5

PLANTS OF MADAGASCAR

DURING the present year no less than four separate collections of plants have been received at Kew from Madagascar, including in the aggregate about a thousand species, represented by specimens complete enough to be botanically determinable. As the hills of the interior of the island attain an elevation of 10,000 feet, its range of climate is considerable. We now know not less than two thousand Madagascar flowering-plants, and probably have almost exhausted its ferns, to which the collectors have paid special attention, and which are about 250 in number, so that we may consider ourselves in a position to draw broad general conclusions as to the botany of the island.

Amongst the tropical types there are a considerable number of endemic genera The lemurs find their parallel in the vegetable kingdom in the *Chlænaceæ*, a natural order whose nearest affinities are with *Tiliaceæ*, *Dipterocarpeæ*, and *Ternstrœmiaceæ*, which is strictly confined to Madagascar, and comprises four genera and about twice as many species, to which the Rev R. Baron, in these new collections, has added a well-marked novelty in a second species of *Leptolæna*. Altogether there are certainly not less than fifty genera confined to the island, some of them very curious types, as *Dicoryphia* in *Hamamelideæ*, *Ouvirandra* in *Naiadaceæ*, *Asteropeia* (placed in the "Genera Plantarum" in *Samydaceæ*, but which Mr. Baron's excellent new specimens will most likely have to be removed to *Linaceæ*), *Macarisia* in *Rhizophoreæ*, *Deidamia* and *Physena* in *Passifloreæ*, *Hydrotriche* in *Scrophulariaceæ*, *Camelia*, *Tannodia* and *Sphærostylis* in *Euphorbiaceæ*, *Pachnotrophe* in *Moreæ*, *Calantica* in *Samydaceæ*, and several each in the orders *Rubiaceæ*, *Melastomaceæ*, and *Compositæ*. To these endemic types the new collections add at last three, *Kitchingia*, a fine new genus of *Crassulaceæ* allied to *Bryophyllum*, with five or six species named after the collector of the first of the four parcels, *Rhodocodon*, a monotypic genus of gamophyllous *Liliaceæ* allied to *Hyacinthus*, and *Micronychia*, in *Anacardiaceæ*, also monotypic, figured lately in Hooker's Icones Besides these the tropical flora of the island contains a large proportion. first, of endemic species of genera known elsewhere; second, of species

common to Madagascar, Mauritius and Bourbon, but not elsewhere known, such as *Pittosporum Senacia*, *Aphloia mauritiana*, *Gouania mauritiana*, *Nesæa triflora*, *Lobelia serpens*, and *Buddleia madagascariensis*, thirdly, of species that spread across Tropical Africa, such as *Haronga paniculata*, *Desmodium mauritianum* and *oxybracteum*, *Gynura cernua*, *Brehmia spinosa*, and *Mussoenda arcuata*, fourthly, of species spread universally through the tropics of the Old World, but not reaching America, such as *Crotalaria stricta*, *Oxalis sensitiva*, *Nymphæa stellata*, *Trichodesma zeylanica*, *Indigofera enneaphylla*, *Avicennia officinalis*, and *Rhizophora mucronata*, and fifthly, of species spread universally through the tropical zone of both hemispheres, such as *Eleusine indica*, *Tephrosia purpurea*, *Drymaria cordata*, *Elephantopus scaber*, *Teramnus labialis*, *Zornia diphylla*, *Waltheria americana*, *Sida rhombifolia*, and *Nephrodium molle*. In Mauritius and the Seychelles there are 145 species which occur also both in Asia and Africa, in addition to 225 which are spread all round the world in the tropical zone, and nearly all these 370 species are now known in Madagascar also. A small proportion of the Madagascar genera and species are Asiatic but not African, and these present collections add to the island flora *Lagerstromia*, *Buchanania*, and *Strongylodon*, three well-marked Indian types.

But perhaps still more interesting, in the light that it throws on the past history of the island, is the relationship of the comparatively limited flora of the mountains of the interior to that of other parts of the world. A certain number of the plants, especially the ferns and fern-allies, are widely-spread temperate species, which now have their head-quarters in the temperate regions of the northern hemisphere, we have instances of this in *Nephrodium Filix-mas*, *Aspidium aculeatum*, *Osmunda regalis*, *Lycopodium clavatum*, *L. complanatum*, *Sanicula europæa*, *Potamogeton oblongus*, *Sonchus asper*, *S. oleraceus*, *Polygonum minus*. Most of the characteristic types of the Cape flora are represented on the Madagascar mountains, but nearly always by species which are distinct from those which are now found in the extra-tropical regions of the main continent. for instance, the Aloes by a couple of species of *Lomatophyllum*, the Heaths by several species of *Philippia* and *Ericinella*, the bulbous Iridaceæ by species of *Gladiolus*, *Geissorhiza* and *Aristea*, the saprophytic *Scrophulariaceæ* by *Harveya obtusifolia*, the special Cape ferns by *Mohria caffrorum*, *Cheilanthes hirta*, *Pellæa hastata*, and *P. calomelanos*, the Proteaceæ by the curious genus *Dilobeia* (which Du Petit Thouars found at the beginning of the century, and of which Dr. Parker has now sent home the first specimens which have been seen in England), and the *Selagineæ* by *Selago muralis* of Bentham, which grows in the grounds of the Queen's palace at Antananarivo. But perhaps the most interesting feature of all is the occurrence of several striking cases of specific identity between plants of the Madagascar mountains and those of the tropical zone of the African continent. The only Madagascar violet (*Viola emirnensis*, Bojer, = *V. abyssinica*, Steud.) only occurs elsewhere high up amongst the mountains of Abyssinia, at 7000 feet above sea-level in the Camaroons, and at 10,000 feet above sea-level at Fernando Po. The only Madagascar Geranium (*G. emirnense*, H. B. = *G. compar*, R. Br. = *G. simense*, *latistipulatum* and *frigidum*, Hochst.) has a precisely similar area of distribution. *Caucalis melanantha* of Bentham is only known in Madagascar and amongst the mountains of Abyssinia. The Madagascar *Drosera* (*D. madagascariensis*, D.C. = *D. ramentacea*, Burch.) reappears at the Cape and the mountains of Angola and the west tropical coast, *Agauria salicifolia*, Hook. fil., which we noted lately as having been gathered by Mr. Thomson on the high plateaux of Lake Nyassa, is found in the Cameroons and on the mountains of Madagascar, Mauritius, and Bourbon, *Crotalaria spinosa* reappears in Nubia, Abyssinia, Angola, and Zambesi-land; *Asplenium Mannii*, Hook., on the mountains of Zambesi-land, the Cameroons, and Fernando Po. As a whole, it would seem that the flora of the Madagascar mountains corresponds closely with that of the great ranges of the tropical zone of the main African continent.

J. G. BAKER

BENJAMIN COLLINS BRODIE, BART., F.R.S., D.C.L.

ON Wednesday, November 24 last, died Benjamin Collins Brodie the younger, a worthy son of a distinguished sire. Born to affluence, but early imbued with the liberal and high-minded views of the great surgeon, he determined to devote his life and energies to the prosecution of science for its own sake, and well has he done his work. Brodie was born in London in 1817, and educated first at Harrow under Longley, and afterwards at Balliol, taking his Master's degree in 1842. In those days it was absolutely impossible to carry out original chemical work at Oxford, and Brodie naturally betook himself to Giessen, where Liebig's name drew students from all parts of the world. There in the summer of 1845 Brodie, at Liebig's suggestion, carried out analyses of certain waxes obtained by Gundlach by feeding bees on different kinds of sugar. The results thus obtained led him to continue his examination of bees'-wax on his return to England, and from his private laboratory in the Albert Road now came forth his well-known researches on the Chemical Nature of Wax (*Phil. Trans.* 1848, 147-170; 1849, 91-108), for which in 1850 he received the well-merited reward of the Royal Medal. These researches will always remain not only remarkable as having given a successful solution of a difficult problem, but as having proved, by careful preparation and exact analysis, the existence in wax of solid bodies which play the part of alcohols, and of which common spirit of wine is a direct lineal descendant. This unexpected discovery of solid alcohols containing respectively twenty-seven and thirty atoms of carbon in the molecule completely confirmed the truth of the views concerning the existence of an homologous series of alcohols first enunciated by Schiel and Gerhardt, and thus placed in firm position one of the chief pillars of the organic portion of our science.

Brodie's next work was not inferior either in importance or in workmanship to his first. In 1850 he published his memoir "On the Condition of certain Elements at the Moment of Chemical Change" (*Phil. Trans.*, 1850, 750-804), in which he carefully investigates the remarkable reducing action exerted by peroxide of hydrogen. Not only does this body lose half its oxygen when brought in contact with oxide of silver, but reduces this oxide to metal. This anomalous action was satisfactorily explained by Brodie, who pointed out that the second atom of oxygen in these peroxides is not only retained in an unstable state of combination, but that when brought into contact with silver oxide a true synthesis of oxygen occurs, two atoms of this element uniting to form one molecule of free oxygen. That this reaction really takes place was shown by Brodie to be the case by careful experiment. These results led him to consider the constitution of the alcohol radicals (*Chem. Soc. Journ.* iii. 405), and to assert in 1851 the important fact, now universally admitted, that the molecule of the radical ethyl contains four atoms of carbon. To him too we owe the prediction of the possibility of the existence of the mixed radicals, a prediction so soon afterwards experimentally verified by Wurtz. Next we find him active as secretary of the Society of which he afterwards became president, viz. the Chemical Society of London, also in lecturing at the Royal Institution on the allotropic changes of certain elements, on the formation of hydrogen and its homologues, in which

he clearly brings forward his views concerning the union of atoms to form the molecule.

In 1853 he published his interesting observations on the conversion of yellow phosphorus into the red modification by heating it to 200° in presence of mere traces of iodine (*Chem. Soc. Journ* v 289) Another very important and difficult investigation which occupied much of his attention about this time was the question of the purification (*Ann de Chimie*, 45, 351) of graphite, and the determination of its "atomic weight" (*Phil Trans.* 1859, 249). By heating graphite with strong nitric acid and chlorate of potash, Brodie showed that, unlike all the other modifications of carbon, graphite yields a remarkable crystalline acid, to which he gave the name of graphitic acid, having the formula $C_{11}H_4O_6$ The existence of this interesting body led Brodie to the conclusion that graphite may be considered as a peculiar radical, to which he gave the name of graphon In the year 1855 Brodie was appointed Waynflete Professor of Chemistry in the University of Oxford, a position which enabled him to throw all his influence into forcing the recognition of chemical science as a proper object of academic training Under his fostering care the science which had hitherto been so long neglected put out distinct signs of life new laboratories and lecture-rooms were built, to which students flocked in numbers, and Oxford saw the unwonted sight of her professor of chemistry busily engaged in original investigation, as well as in the tutorial duties of his chair The discovery of those singular and dangerous bodies, the peroxides of the organic radicals (*Proc.* Roy Soc. ix. 361, *Phil. Trans* 1863, 407), was made in the laboratory of the New Museum. The same laboratory soon afterwards saw the minute and careful investigation on ozone (*Phil Trans* 1872, 432), which proved beyond doubt or cavil that the supposition that the molecule of ozone is represented by the formula O_3 is both necessary and sufficient to explain all the observed phenomena

Next we find him experimenting on the synthetic production of the hydrocarbon methane, as well as of formic acid, by the direct union of hydrogen and carbon monoxide under the influence of the electric spark. Then he examines the effect of an induced electric current upon pure and dry carbonic acid, and proves that this gas is partially decomposed with formation of carbon monoxide and oxygen, the latter gas being converted into ozone And he then proceeds to ask whether the ozone thus produced is identical with that obtained from ordinary oxygen, and by a series of careful quantitative experiments demonstrates the identity of the ozone from these two sources

This was Brodie's last experimental investigation Ere long he resigned the Chair of Chemistry at Oxford, regretted by the whole University. He retired to his charming seat on the summit of Box Hill Neither his own scientific activity nor his deep interest in the scientific work of others ceased on his withdrawal from professional life Before his retirement he had put forward (*Phil Trans.* 1866, 781-860) in his "Calculus of Chemical Operations," views altogether novel respecting the nature of chemical change. In place of the usual mode of considering this as due to a change in the relative positions of the atoms of which matter is composed, Brodie founds his theory of the constitution of chemical elements and compounds on the simple volume-relations discovered by Gay-Lussac to exist between these substances in the gaseous state To hydrogen Brodie gives a simple symbol, because the unit of hydrogen can, as he expresses it, be conceived as made at once by one operation, whilst to oxygen he gives a double symbol, because it cannot, according to him, be made by less than two operations. The element chlorine is supposed to be made up of three operations, and a treble symbol is given to this body Concerning the probable or possible decomposition of the elements Brodie naturally speculates His analysis had led him to suspect that "chemical substances are really composed of a primitive system of elemental bodies analogous in their general nature to our present elements, some of which we possess, but of which we possess only a few" ("Ideal Chemistry," p 54) But no experimental evidence of this fact was offered by him, and none of a satisfactory character was otherwise forthcoming, until Victor Meyer announced his belief that chlorine was capable of undergoing decomposition at high temperatures

Here was a proof of the truth of Brodie's complex symbol! Sad to say, further experiment has not corroborated this conclusion. No substance differing essentially from chlorine has yet been got from this body. Even the change of density at a white-heat appears in the case of chlorine to be, to say the least, doubtful So we are left for the present, and the author of the "Calculus of Operations" is left for ever, without the experimental confirmation of his conclusions which he so much desired Whatever may be the verdict of the future as to the value of Brodie's Calculus, there is no doubt that science is indebted to him for an altogether new view of chemical combination obtained by a systematic analytical process '

This occasion is not a fitting one to enlarge upon the high personal character of the late Sir Benjamin Brodie Suffice it to say that in all relations in life, in the domestic circle as in society, in the chair at Burlington House as in that at Oxford, he displayed all those qualities of heart and head which alone give dignity and sweetness to life, the possession of which ensures for his memory a lasting place in the minds of all those who were fortunate enough to count him amongst their friends H. E R.

THE PHYLLOXERA IN FRANCE

THE new vine-disease, due to the *Phylloxera vastatrix* Planchon, has already caused much damage to the French vineyards and wine-production From the taxes arising from that national industry France derives a considerable part of her revenue; and this subject has consequently occasioned innumerable publications and investigations Of the latter some have been empirical and without result, others, which were conducted scientifically, have alone been of any use It was moreover absolutely necessary to have an unswerving confidence in exact observations, in order to persevere in making experiments which are often disturbed and rendered apparently self-contradictory by the secondary and ever-varying conditions of cultivation These experiments have at last been crowned with success, and now there are decidedly good grounds for hope For the last two years the public have shown a steadily increasing confidence in scientific methods

One of the most distinguished chemists, a man of whom France is proud, and with whom readers of NATURE are well acquainted, especially as they were lately presented with his portrait and biography, M Dumas, applied himself to the study of the Phylloxera, and pursued his task from day to day with keen determination, notwithstanding the attacks of some and the discouraging advice of others. It is his well intentioned and unceasing diligence that we must thank for never having lost heart, it is to him that those results are due which are presently to be indicated When the pébrine-disease was raging on silkworms in the South of France, it was by his personal suggestion and repeated encouragement that M Pasteur agreed to devote himself to that difficult study, and it is the same gentle influence and guidance that have directed the present writer, together with several others, especially MM Balbiani, Duclaux, and Mouillefert

Henceforward the principal problems raised by the study of vine diseases are solved They were solved one after another in regular order, as fresh light appeared and the ends to be aimed at became more definite It cannot

be too frequently repeated that that is due, not to a happy hit or to guess-work, but to an unceasing and skilfully conducted struggle which was kept up with indomitable persistence in the midst of obstacles caused by many selfish interests. Times are greatly changed since M. Dumas[1] protested, in discreet but unmistakable language,

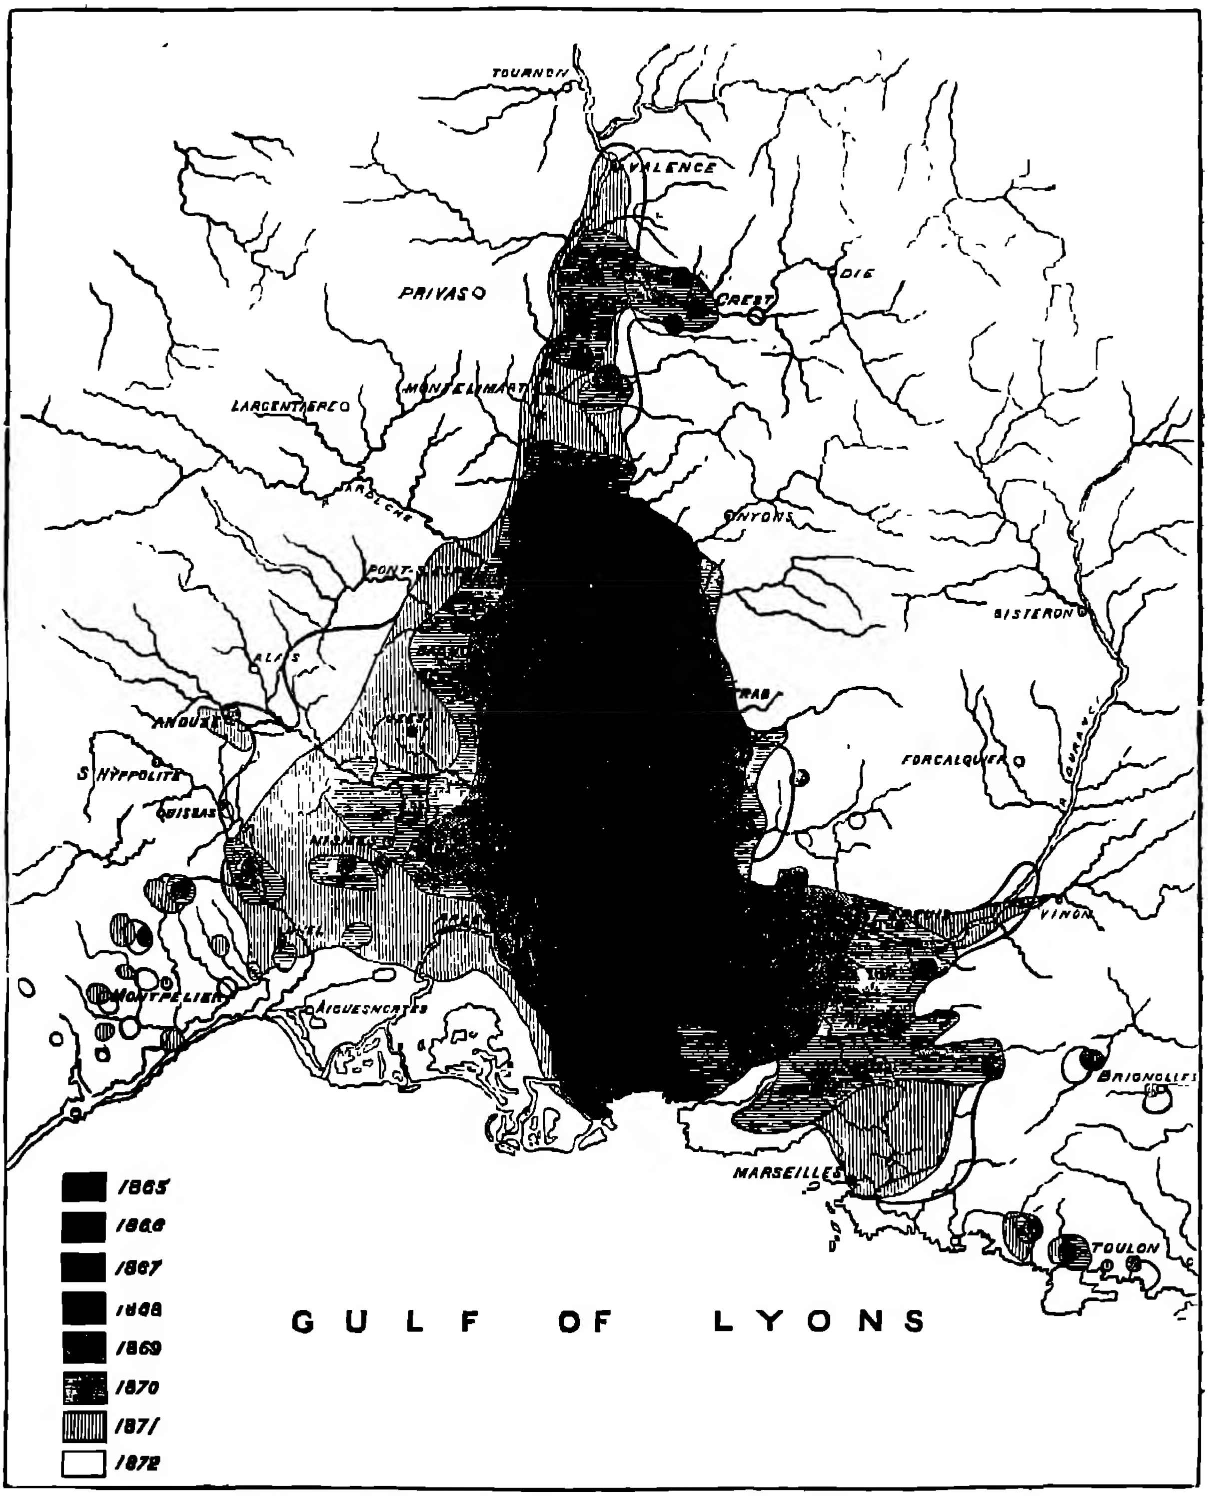

FIG 1 —Map showing the spread of Phylloxera in France from 1865 to 1872 (See NATURE, vol x p 504.)

against the indifference of a French Minister of Agriculture who tried to beat down a grant of 10,000 francs necessary for continuing the scientific investigation. On the same occasion he drew attention to the praiseworthy initiation taken by the railway companies and by various private gentlemen. M. Tirard, the present Minister of Agricul-

[1] Académie des Sciences, February 23, 1874.

ture, has obtained several large grants,[1] and proposes to ask still much larger ones for the approaching campaign, being anxious to assist in every way the laborious struggle. M. Tisserand, the new Director at the Office of Agriculture, a man of great energy and ability, has resolved to back up all his efforts, and has instituted a special central staff to take charge of all documents and operations. The Higher Phylloxera Commission, formed by order of the Minister, has also shown activity. it has adopted a general legislative scheme in order to supply the Government with the arms necessary to defend the threatened territory.

Switzerland and Germany soon adopted similar measures; and with reference to England we must remark that the Phylloxera question may soon become something different from a mere matter of curiosity. Are there no important vineyards in England? We are told that at Liverpool alone, in the "Vineries," there are forty hectares of vines grown under glass. The Phylloxera was observed by Mr. Westwood before it was known in France. It is still found here and there in Ireland, in Scotland, and not far from London itself. By the admirable cultivation under glass, in which English vine-growers are unrivalled, it is kept within narrow limits, but it might

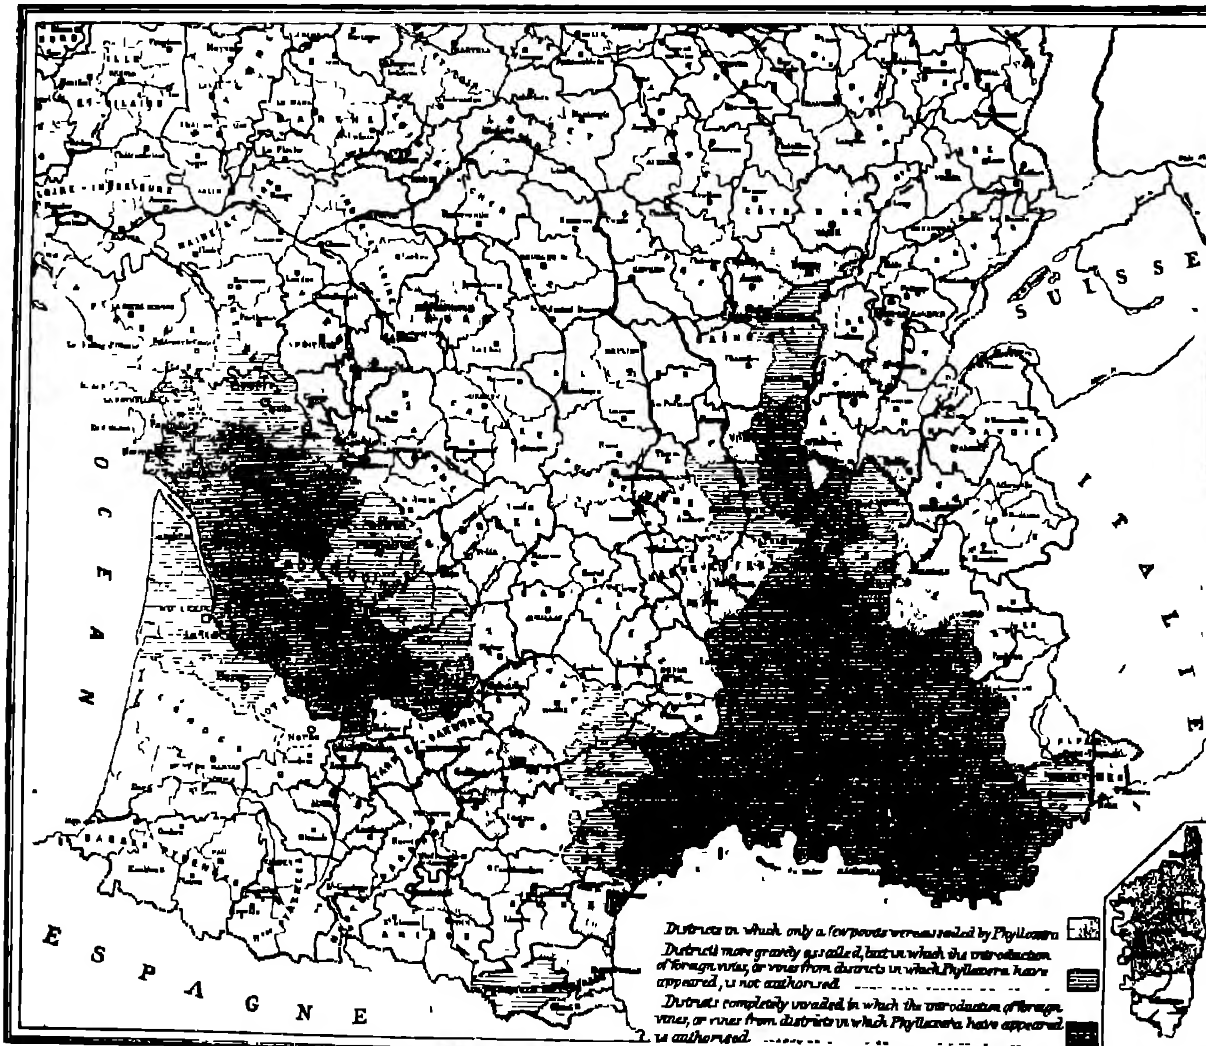

FIG. 2.—Map showing the spread of Phylloxera in France up to 1880.

be communicated to other places. In Switzerland one single parcel of plants is reported to have brought the parasite to Geneva, Schaffhausen, and Neuchâtel In any case, should an international convention be instituted, the enforced examination at the frontiers would hamper the trade in those magnificent English grapes The rigorous measures taken against the cattle-disease suffice to show what may be necessary in order to defend the leaf or shoots of the vine.

Extent of the Disease.—The increase of the disease is considerable; thus at the beginning of 1877 there were only twenty-eight departments attacked, whereas at the beginning of 1879, according to the official statistics, there were thirty-nine. Those in the previous year, in order of date,[1] were Loir-et-Cher, Haute-Garonne, Gers, and Corrèze. In 1878 Aude, Pyrénées-Orientales, Haute-Loire, Vienne, Indre, Côte-d'or, and Savoie. In 1879, Haute-Savoie, Jura, Arriège, and Tarn. A special inquiry enables us to determine what area had been invaded in the end of 1879 —the invaded vineyards which had not yet succumbed were 319,760 hectares in

[1] One of 500,000 francs, which has since been doubled.

[1] "Le Phylloxéra, &c., Rapports publ par le Ministère de l'Agric." 8 fasc., p. 9. (Paris: Masson, 1879)

extent, or 76,722 more than the preceding year, the vineyards destroyed, 474,760, or 101,317 more than the preceding year (1878).

There is unfortunately reason to fear that the isolated points may join each other and the affected patches unite. The patches, whether distinct or uniting, increase about 15 kilometres every year; and since the increase in any direction is proportional to the time, the increase of area is as the square of the time In other words, after 2, 3, 4, 5 years, the evil is increased 4, 9, 16, 25 times By merely looking at a map showing the extent of the plague, one can form an idea of the invading march of the terrible insect

Yet there are actually men of science in France who join in depreciating those who are employed to battle with this fatal disease It is sad to see the reception met with by those who have sacrificed their time, health, and scientific reputation to undertake duties so beneficial to their country. "They are merely wasting their time," say they, "much better not have left their personal duties," and, true enough, those of whom this is said have cruelly felt its truth. M Dumas, however, is not one of those.

Several years ago a prize of 300,000 francs was instituted to encourage investigations as to the best remedy against the phylloxera Much ingenuity was wasted, many absurd remedies proposed, and it is curious to note the substances which were lauded by the inventors They were for the most part the same, mixed in different proportions—tars, sulphur, lime, soot, urine, phenic acid, and salts of copper or iron. Patient research and scientific study have alone produced certain results.

These results, however, were not accepted and acknowledged without difficulty. Objections were accumulated and many instances of partial failure were brought together, ill-will and inertia playing an important part in the business Local influences, political opinions, and other extraordinary considerations, one after another, opposed or favoured the results which were gained At present the question has once for all entered upon a better path, the charlatans and pretended vine-doctors having entirely lost their credit We are in possession of four modes of treatment which are really efficacious, though they vary in their effects in different cases The struggle therefore should be maintained

The various conditions of application and the entirely different principles which the application follows explain the divergence of opinions and methods The scientific remedy is given practice will decide which of the four methods is at the same time most efficacious and most economical. This happy result must mainly be attributed to the Commission of the Academy of Sciences, which was presided over by M. Dumas, who was the very soul of it This Commission sent "delegates," who severally studied special clearly-defined questions, like officers sent by a general to make a reconnaissance in a country

The commissions instituted in the departments did much good work, especially that of Hérault, which contained several distinguished members, both vine-growers and scientists: MM. Marès and Planchon, Members of the Institute of France; M. Bazille, Senator, M. Vialla, &c. We must also notice particularly the Viticultural Station at Cognac, which was established by private subscription, after the English manner,—a thing of rare occurrence in France. It was M. Lecoq de Boisbaudran, now Member of the Institute, the discoverer of the metal *Gallium*, who first started the idea, and triumphantly realised it in his native town. The principal houses in the trade made it a point of honour to subscribe, and the expenses in four years reached a sum not less than 32,000 francs. It was there that the general experiments as to "insecticides" were made, in accordance with the simple method proposed by M. Cornu, Director of the Viticultural Station, in order to determine definitively what substances are powerless This work of "clearing the way" necessarily occupied several years, the practical part being energetically carried out by M. Mouillefert, of the National School of Agriculture at Grignon, near Paris, sub-director of the Viticultural Station Towards the end of the first year they began to distinguish clearly the small group of substances which alone should be utilised. Amongst them was carbon disulphide (CS_2), which had been indicated by Baron Thénard, abandoned and then eagerly resumed by the enthusiastic M Monestier, and at last rejected in a general manner in the end of 1873 and during 1874

The carbon disulphide by itself appearing too dangerous to human life, M. Dumas happily started the idea of using it in combination with sulphide of potassium, forming the sulpho-carbonate of potassium ($KSCS_2$), which is both a powerful "insecticide" and an energetic manure

The conclusions reached by the experiments made at Cognac were published towards the end of 1874 in the Report of the Academy of Sciences (last quarter), and the author can still defend every one of them as they were then deduced, a rare circumstance in connection with the phylloxera.

Under the happy influence of the Minister of Agriculture, the vine-growers were grouped into "vigilance-committees" for watching, and "syndicates" for treating, the vines Thus the indifference of some and unreasoning excitement of others were followed by energetic preparation for the struggle At the end of 1878 there were sixty committees instituted in fifty-six departments, and now there are 221, embracing sixty-one departments Some of them have obtained decidedly successful results, and thus furnished a powerful incentive for the others to persevere.

The expense of the applications is still considerable, but in any case the most valuable vines are now out of danger. The more common vines will at first cost a good deal, but we are confident that scientific skill will supply sulphate of carbon either free or in combination at a cheaper rate, and that practical experience will render its application more easy and less expensive France will thus continue to produce her wines, and have the pleasure of offering them to her friends and neighbours This, though apparently a mere wish, is an actual statement of fact

MAXIME CORNU,
Delegate of the Academy of Sciences, and formerly Director of the Viticultural Station at Cognac

NOTES

THE following are the arrangements for the Friday evening meetings of the Royal Institution of Great Britain before Easter, 1881 —January 21, Warren De La Rue, D.C.L., F R S., Sec. R I, The Phenomena of the Electric Discharge with 14,400 Chloride of Silver Cells, January 28, Dr Andrew Wilson, F.R S.E, The Origin of Colonial Organisms; February 4, Dr Arthur Schuster, F.R.S, The Teachings of Modern Spectroscopy; February 11, Robert S Ball, LL D, F.R S, The Distances of the Stars, February 18, Sir John Lubbock, Bart, M.P, D.C L., F.R S., M R I, Fruits and Seeds, February 25, Dr. J. S Burdon Sanderson, LL.D, F.R S, Excitability in Plants and Animals; March 4, Sir William Thomson, LL.D., F R S, Elasticity viewed as Possibly a Mode of Motion; March 11, uncertain, March 18, Wm. H. Stone, M D., Musical Pitch and its Determination, March 25, Alexander Buchan, M.A., F.R.S.E., Sec Met. Soc. Scot., The Weather and Health of London, April 1, uncertain; April 8, Prof. Tyndall, D.C.L., F.R.S., M.R.I.

THERE is nothing that will tend to keep our learned societies in so wholesome a condition as healthy public opinion; it is

therefore a matter for congratulation when we see a paper like the *Times* taking an interest in the organisation and work of the Royal Society, and giving its opinion on these, even when the justice of that opinion is questioned by many. From a leading article in the *Times* of Thursday last, on Mr. Spottiswoode's address, we take the following passage:—"The election to the vacancies in its ranks has of late years been too manifestly governed by a tendency to set up as an idol something which it is technically fashionable to call 'research,' and to ignore the far higher mental effort which is required for successful ratiocination. A man sets to work with a microscope and a test-tube, performs a number of curious experiments, and announces an interesting discovery which can neither be confirmed nor refuted by any one who does not follow precisely in his tracks. Such an experimenter, before now, has been rewarded by the privilege of placing the letters F R S after his name, although, when the privilege had been conferred beyond recall, it may have been shown that his 'research' was undermined by the neglect of some essential precaution, and that his conclusion was erroneous. On the other hand, the man who gathers up the scattered facts ascertained by others, and founds upon them a weighty and important generalisation, is not on that account thought worthy of the Fellowship, and if he desires to obtain it is almost compelled to engage in some colourable 'research' as a means of gratifying his wishes. The principle thus acted upon is as much a mistake as it would be to glorify a carpenter or a mason and to ignore an architect, and it points to a narrowness of view which might profitably give place to a more accurate sense of relative proportion. The award of a medal to Prof Lister, notwithstanding the great and direct utility of his work, is possibly an indication that better counsels may in time be expected to prevail."

WE understand that the Rev. Osmond Fisher has in the press, and will shortly publish, a new work entitled "Physics of the Earth's Crust." The volume will contain selected and revised portions of papers which have appeared at various times in the *Transactions* of the Cambridge Philosophical Society and other scientific publications, together with new matter. Mr. Fisher will in some chapters apply mathematical methods, but there will be found much matter calculated to interest those readers who do not care for that mode of reasoning.

THE meeting of the British Medical Association for the year 1881 will be held at Ryde, in the Isle of Wight, to which locality the Association has received a cordial invitation from nearly the whole of the medical profession in the island Mr Benjamin Barrow, an old and much-respected practitioner in Ryde, has been appointed president-elect. The Council of the Town of Ryde have passed a unanimous resolution that the whole of the Corporation Buildings, which are numerous and spacious, shall be placed at the disposal of the Reception Committee. There is every reason to believe, that the many beautiful private grounds in the Isle of Wight will be thrown open to the Association. The president will give a garden party to the members and residents in the island. A *soirée* will be held in the Town Hall and adjoining buildings The address in medicine will be given by Dr. John Syer Bristowe, London, of St. Thomas's Hospital, the address in surgery will be given by Mr. William Dalla Husband of Bournemouth, Consulting Surgeon to the York County Hospital; and an address in obstetric medicine by Dr. John G. Sinclair Coghill of Ventnor. Such has been the spirit with which the movement has been taken up by the Members of the Association and profession in the Isle of Wight and Ryde that the meeting bids fair to rival any previous meeting both in science and pleasure.—The following grants in aid of scientific investigation for the year were made, viz:—Dr. McKendrick and Committee, Glasgow, for a continued investigation on anæsthetics, 25*l.*, Dr Gerald Yeo, London, on the efficacy of the antiseptic method in injuries of the brain, 50*l*, Dr Shin, London, for a continued investigation on parasitic skin diseases, 25*l.*, Mr W. North, London, for a continued investigation on the relations which exist between nitrogenous egesta and muscular work, 50*l*, Dr D. J Hamilton, Edinburgh, an investigation on the pathology of the brain, 30*l*, Mr. Watson Cheyne, London, an investigation on the relation of organisms of septic disease, 25*l*, Dr. Augustus Waller, London, an investigation on the time and relations of muscular contractions in the human body in health and disease, 20*l.*; Dr. Alexander Ogston, Aberdeen, a continued investigation on the relation between bacteria and surgical disease, 10*l.*; Dr. Newman, Glasgow, a renewed grant in aid of an investigation on the functions of the kidney, 10*l.*, Drs Braidwood and Vacher, Birkenhead, to illustrate the third and final report on the life history of contagium, 20*l*

IN the Vienna Gewerbeverein, Herr F. Siemens has been lecturing on his "regenerative gas-burner," in which the departing heat of the flame serves for pre-heating the air and the gas to be consumed The products of combustion of the flame, collected in a short chimney, flow away cold, either into the room or to the open air The light, according to measurements, has twice to three times the illuminating power of the best-known gas burners, and is remarkably white and steady

THE death is announced of Dr. Lauder Lindsay, F R S E. F L S., at Edinburgh, on November 24, at the age of fifty. Dr Lindsay's name must be known to our readers as an occasional contributor to our columns Dr. Lindsay did some good work in botany and geology, and took special interest in the subject of intelligence in the lower animals. In 1870 he published a "History of British Lichens," and quite recently we reviewed his work on "Mind in the Lower Animals," published last year

ON Monday a deputation, consisting of Mr. Ernest Hart, Prof. Chandler Roberts, F.R S, Col. Festing, the Rev H V. Le Bas, the Rev S. A Barnett, Mr S. Hadley, Mr. W. R. E. Coles, and others, had an interview with the Lord Mayor at the Mansion House, to interest him in the efforts now being made by the joint committees of the National Health and Kyrle Societies to reduce the mischief arising from the present excessive production of smoke in the metropolis. Mr Ernest Hart said the Societies thought that a very great deal might be practically done to make the atmosphere in London as pure as that in Paris It was proposed to conduct trials of the various kinds of fuel and to promote competitive testing of the appliances available at present, or which might become available, for the purpose of lessening the production of smoke. The smoke proceeding from the fires of private houses might be materially lessened by the use of improved apparatus, and that from factories might be abated with little interference with the manufacturing interests if the employers would only co-operate with the Societies towards that end There was about to be an exhibition at South Kensington of the different kinds of apparatus and fuel, which would be practically tested. They now asked the Lord Mayor to let them bring the matter before the notice and attention of the citizens by means of a meeting at the Mansion House on the subject. The Lord Mayor thought it a matter well deserving the public attention, and he would gladly allow a conference in the Long Parlour of the Mansion House on Friday, January 7.

IN connection with the subject of Incandescent Electric lighting it is of interest to notice in the New York *Times* an account of an experiment in this direction. At a reception given on the evening of November 17 by Prof Henry Draper to the members of the National Academy of Sciences, a part of his house was

lighted by the Maxim light. The laboratory was lighted by eight Maxim electric lamps, which were screwed into the chandeliers in place of the ordinary gas burners. The large laboratory, it is stated, was as light as the open fields at noonday, and there was no flickering or unsteadiness in the light. In shape the lamps are precisely similar to those used by Edison, but H S Maxim, who holds the patent on them, claims to have improved on Edison's plan, by making his lamps more permanent. Like Edison, he uses a carbonised fibre, in the form of a horseshoe, but unlike him, does not inclose this fibre in a vacuum, and considers that his lamp is complete. An atmosphere of gasoline vapour is introduced into the glass globe which holds the carbonised fibre, and in this atmosphere the fibre is gradually heated by the electric current. As soon as the heat reaches a sufficient intensity it begins to decompose the hydrocarbon of which gasoline vapour is composed, and if there are any weak spots in the filament the freed carbon is deposited there and strengthens the fibre. A current of increasing intensity is thus carried through the carbonised fibre, which constantly grows at the expense of the gasoline vapour, and finally becomes of a uniform power of resistance throughout its whole length. The gasoline vapour is then pumped out of the globe and the lamp is ready for use. The Maxim lamps are said to give a larger amount of light than any incandescent lamp hitherto constructed. According to experiments made by Prof. Morton, of the Stevens Institute, it appears that the lamps have produced light at the rate of 600 candles per horse power of current. Each of the eight lights in Prof Draper's laboratory had an illuminating power of about fifty candles. The electric current for the lamps was furnished by a Maxim dynamo machine, which was driven by a gas engine of four-horse power, located in the laboratory. The Maxim machine has an armature something like that of the Gramme machine, while its field magnets resemble those of the Siemens machine

THE recent importations into this country of cinchona bark from Jamaica and the high prices realised have been the means of causing a considerable amount of attention to be drawn to this new source of supply. From a document recently drawn up by Mr. Morris, Director of Public Gardens and Plantations in Jamaica, it seems that the results of the cinchona sales for the year 1879-80 have been as follows:—Quantity of bark shipped 27,399 lb., gross amount realised £5380 9*s* 6*d*., net sum realised £5146 8*s*. 7*d*. Without going into details it will suffice to show the superiority of Jamaica bark over that from Ceylon by saying that for red "root bark" the highest price for Jamaica produce was 4*s*. 8*d* per pound for "good root" as against 2*s*. 6*d*. for "good root" from Ceylon, thus showing an advantage in favour of Jamaica root bark to the extent of 2*s*. 2*d*. per pound. Thus again for "twig and small ordinary" bark of *C. succirubra* Ceylon produce obtained from 2½*d*. to 1*s* per pound as against 10½*d*. to 1*s*. 6*d*. per pound for similar bark from Jamaica. From this, together with the fact that an enormous number of plants are now in stock in Jamaica, the future of cinchona cultivation in that island seems to be ensured.

IT is stated in an American contemporary devoted to electrical topics that a call has lately been made on the shareholders of the Edison Electric Light Company to the amount of sixty dollars per share. The object of the call was "to meet the expense of recent experiments."

IMPORTANT trials have been made lately on the Rhine, in order that navigation may be carried on at night by means of the electric light. It is hoped that soon satisfactory results will follow, which will probably develop an entirely new phase in river navigation.

IN the neighbourhood of Agram, at the mountainous places St. Simon and Remete, some shocks (of slight importance) were felt up till December 1. At Dortmund, on November 27, a considerable shock occurred at 5 50 a.m. It lasted several seconds, and the direction was south-south-east, barometer 756, temperature 7° R. A rather smart shock of earthquake, accompanied by a loud subterranean noise, was felt at Schaffhausen on Wednesday night last week The Rev. Dr. Dixon of Beragh, near Omagh, writes that a slight earthquake shock was distinctly felt there on the afternoon of Sunday, November 28, at about half-past five. The peculiar character of the shock was most marked. It appeared to travel from south-west to north-east.

IN the course of his experiences as a medical missionary among the Mongols the Rev. James Gilmour has gathered some interesting information regarding their inner life, but perhaps the most curious item is that Mongol doctors are not entirely unacquainted with the properties of galvanism. It is said that they are in the habit of prescribing the loadstone ore, reduced to powder, as efficacious when applied to sores, and Mr. Gilmour states that one man hard of hearing had been recommended by a lama to put a piece of loadstone into each ear and chew a piece of iron in his mouth!

THE French Great Western Company instituted last year a competition in the large hall of St. Lazare Station, between the Jablochkoff and Lontin light and the gas company. The conclusions were in favour of the electric light, but the gas company having declared that they would abolish entirely the special price charged on the Great Western Company if they declared in favour of gas, the gas lamps have been restored.

Les Mondes gives the following old recipe for testing the age of eggs, which, it thinks, seems to have been forgotten. Dissolve 120 grammes of common salt in a litre of water. An egg put in this solution on the day it is laid will sink to the bottom; one a day old will not reach quite to the bottom of the vessel, an egg three days old will swim in the liquid, while one more than three days old will swim on the surface.

THE *Launceston Examiner* (Tasmania) of October 6 contains some account of a shaft that had been sunk for a well at a brewery at Launceston, near the river. Little water was met with, but some interesting observations were made The shaft had been sunk to a depth of ninety eight feet. The strata passed through are of a very interesting character. For a little over thirty feet strong clay was met with, then deep beds of compact sand separated by bands a few inches thick of fine quartz conglomerate. About forty feet from the surface considerable quantities of partially carbonised wood were found, extending thence to the bottom of the shaft. The wood is evidently pine, and appears to be identical with that found in the shaft of the Working Miners Company at Brandy Creek, at a similar depth below the river. The grain of the wood is perfectly distinguishable, but the transverse fracture is black and lustrous like jet. The trees must have been of a large size and very abundant, and the great mass of earth that has accumulated above their remains enables one to form some idea of the vast period that has elapsed since they flourished. The great depth of the stratum in which this fossil wood occurs proves that its deposition must have proceeded without material interruption through vast periods of time. It is a little curious that though vegetable remains occur so profusely in the freshwater deposits of the Windmill Hill, and at considerable depths both here and at Beaconsfield, no trace has yet been found of contemporaneous animal life.

THE *Cape Argus* for November 6 contains a full report of a paper read at the Cape Philosophical Society by Mr J. G. Gamble, containing many useful suggestions as to important problems, especially in meteorology and geology, that await solution in South Africa. Residents and travellers in South Africa would no doubt find the paper suggestive.

PHYSICAL NOTES

MR. J. E. H. GORDON has lately patented a method of producing light from electricity based upon Mr. Spottiswoode's suggestion to apply the alternating-current magnetoelectric machine of De Méritens to the induction-coil Mr. Gordon arranges small balls of platinum or iridium, or of an alloy of these metals, at the ends of fine platinum rods in pairs in the middle of a suitable globe, and causes to pass between them a rapid succession of sparks whereby they are raised to incandescence There is no consumption of carbon or any other substance, and the lamps may be connected either in series or in parallel branched arcs. The principal remaining disadvantage is the noise attendant on the rapid sparks. A mechanical contrivance is added to bring the knobs near together when no current is passing in the primary coil. The induction-coils used are of comparatively small size

M TERQUEM (*Jour. de Phys.*, October) prepares, for the receivers of air pumps, brass plates with a circular groove, in which is put a mastic fusing about 60°. The plate is placed over a vessel of heated water, and when the mastic is fused the receiver is brought down into the groove. When cool, the plate adheres to the jar. These receivers are tubulated, and a caoutchouc stopper in the tubule holds a tube bent at a right angle and provided with a stopcock like those used by M. Carré in his air-pump For experiments with the air-pump several receivers with their plates can be easily prepared beforehand.

M. LIPPMANN points out (*Jour. de Phys.*, October) that full justice has hardly been done to Carnot with reference to his law (in thermodynamics). It seems to have been forgotten that he verified the law directly by experiment, and did not merely (as is found stated in excellent treatises) furnish a demonstration *à priori* based on the indestructibility of heat This is doubtless due to the fact that Carnot's original work has long been exhausted and unobtainable M Lippmann considers that work a mine imperfectly explored.

EXPERIMENTS have been made by M. Heschus of the St Petersburg Physical Society, as to the variations of volume and coefficient of elasticity of palladium and its alloys under the influence of hydrogen absorbed. The alloys contained 25 per cent. of gold, silver, and platinum Wires 500 mm long and 0·4 mm. diameter served successively as cathode in electrolysis of dilute sulphuric acid in a long vertical glass tube, where they were stretched by weights so that their length could be measured directly with a cathetometer The alloy containing silver showed the greatest increase of length, 11·7 mm., palladium-platinum 6 14 mm., pure palladium 5 mm, and palladium-gold only 0 9 mm With a current of six bichromate elements, the elongation, very rapid at first, reached its maximum after nearly an hour The shortening after breaking the current proceeded in a similar way, but less rapidly, *e.g* for palladium wire it was only 2 6 mm after twenty-four hours. Some experiments were made with the aid of a recording apparatus, and they also proved that, contrarily to Graham's opinion, the absorption of hydrogen takes place more quickly than the reverse action, and even when electrolytic oxygen is made to act on the wire (used as anode) M. Heschus made a special delicate apparatus for measuring small variations in the length of wires. With this it was proved, that during the first day the shortening of the wire charged with hydrogen decreases very quickly, about the third day it becomes constant; it again decreases rapidly about the seventh day, then approaches zero asymptotically. This agrees with MM. Troost and Hautefeuille's experiments on the tension of hydrogen of palladium.

A PLUVIOMETER which registers the quantity of rain, and the duration and hour of the fall, is described by S. Grimaldi in *Rivista Scientifico Industriale* for October 15.

IN a recent note to the Vienna Academy, on the relation of the daily and yearly variation of temperature to the eleven-years sun-spot period, Herr Liznar first compares observations of the daily variation at thirteen places (including St. Petersburg, Calcutta, and Hobarton), and finds for all some correspondence with the sun-spot curve. The curve from data for Vienna, Prague, Caslan, Brünn, and Trieste from 1857–70, brought to an average, shows, for the minima of this variation in 1859–60 and in 1870–71, a very good agreement with the corresponding maxima of the sun-spot curve; while the maximum of the variation precedes the minimum of the spots by about two years With regard to the yearly variation of temperature, Dr. Hahn's results for Leipzig are fully confirmed by data from eight other places in Europe, the variation showing a maximum and minimum corresponding to the maximum and minimum of spots.

THE combinations formed by phosphuretted hydrogen with hydrobromic and hydriodic acids have been long known. Its combination with hydrochloric acid has lately been effected by M Ogier (*Jour. de Phys.*, November) by compressing equal volumes of the gases in M. Cailletet's apparatus Compressing about 20 atm. at + 14°, small yellowish bright crystals appear, and with sufficient pressure the two gases disappear entirely (if the mixture have been well made), the tube being covered with a crystalline coat without trace of liquid. If the upper part of the tube be heated with tepid water (+ 20°), the compression produces a liquid layer If the tube be slowly cooled, and 60 or 70 atm. maintained, so as to get only a small layer of liquid, the combination forms slowly in crystalline state. Sudden compression, without external heating, will also produce the liquid. On the other hand, if before there is any deposit of crystals the pressure be relaxed (from 25 atm *e.g*) one perceives not a mist, but small, light, solid flocks, which slowly go down the sides of the tube and disappear. The combination can also be produced under cold without pressure, crystals are formed about − 30° If the compound exist in the gaseous state, it is almost wholly dissociated at ordinary temperature and pressure

AN amplifying barometer has been invented by M. Debrun (*Jour. de Phys.*, November) Suppose a Fortin barometer, in the tube of which the mercury is kept at a constant height The cistern has two other vertical tubes open to the atmosphere, one rising out of the mercury, the other from water over the mercury The variations of the water in the latter are read with the aid of a scale, and they are thirteen and a half times greater than those of the mercury in the other open tube.

RECENT experiments in capillarity by Herr Volkmann (*Ann der Phys.*, No. 10) have led him to the following results —1 The influence (affirmed by Wilhelmj) of curvature of the wall on constants of capillarity cannot be maintained, and is explicable by the supposition of a faulty determination of specific gravity (The arrangement of the index is also objectionable) 2. Observation of the height of rise between parallel plates warrants the assumption of a constant wall-layer, on which the liquid rises. 3. The thickness of the wall-layer in the case of neat's-foot oil and alcohol is found constant for plates and tubes at 0·004 mm. 4. In so far as the results with neat's-foot oil and alcohol may be extended to other wetting liquids, no influence of curvature of the wall on constants of capillarity is demonstrable.

PROF. SILOW of Moscow has studied the magnetism of iron chloride solution by the method of induced currents (*Ann der Phys.* No. 10), and finds that the coefficient of magnetisation is not a constant, but a function of the force of separation. As the latter gradually increases, the former at first increases too, and pretty quickly, but reaches a maximum and then decreases, first quickly, then slowly. The liquid is therefore relegated to the same class of magnetic bodies as iron, steel, or nickel, and the author considers that probably all magnetic bodies show this rising and sinking of the coefficient.

IN a paper which appears in the *Ann. der Phys* (No 10), Herr Hankel gives the chief results of his study of the photo- and thermo-electric properties of fluor-spar. He states, *inter alia*, that the middles of the cube-faces become, in light, negative, the tension decreasing towards the edges, and especially the angles, which often show the opposite polarity. It is the chemical rays that act. The carbon electric light does better than sunlight. Sparks between two Leyden jars give the effects, but the light of Geissler tubes does not. Green Weardale crystals were the most excitable (of the specimens tried) The intensity of the effect generally grows with the depth of the colouring The tensions produced by light do not change to those of opposite sign when the crystal is put and kept in the dark. Crystals long exposed to light are weakened in excitability. A moderate heating (to 130° to 150° C.) exalts the photoelectric effect. As to thermoelectricity, rise of temperature produces tensions of the same sign as illumination does. In cooling, the opposite electricities appear. In many crystals weakly excitable by light, the thermoelectric tensions are greater than the photoelectric (especially in the case of brown-red or brown-violet crystals)

GEOGRAPHICAL NOTES

SOME time back it was publicly stated that Commander Cheyne and his friends intended to apply to the Geographical Society for countenance and support to their plans of Arctic exploration. A deputation accordingly waited on Lord Aberdare, the president, on October 12, and, in pursuance of a suggestion he then made, a statement of Commander Cheyne's plans was lately drawn up by a committee for submission to the Council of the Society This has been considered, and in reply the President and Council regret that the scheme, as explained by the statement, does not commend itself to them as one containing the elements of success and of usefulness, and that, even if it were feasible, the means proposed to be adopted for encountering the great dangers and difficulties necessarily attendant upon such an enterprise, do not appear to them sufficient. We believe the Geographical Society is to take up the subject of Arctic exploration this session An Arctic Committee will be appointed to bring together all that has been done since the last English expedition, to enable the Society to decide what steps they should take.

THE post of honour in this month's issue of the Geographical Society's *Proceedings* is naturally assigned to Mr J Thomson's report of the journey of the East African Expedition, of which we have already given a *résumé*. It is illustrated by a map showing his route, constructed from the explorer's original map and other sources. There is also a useful little map of a route from Kagéi to Tabora, by the Rev C. T Wilson of the Church Missionary Society's Nyanza Mission Capt. A H. Markham's "Visit to the Galapagos Islands in 1880" follows, with some observations by Mr. Osbert Salvin on recent additions to our knowledge of the fauna of the group From the geographical notes we learn that medals and other rewards are to be presented to Mr Thomson's native followers, and that Dr. Kirk is to receive the formal thanks of the Society for the important services he rendered to the East African Expedition. Some interesting extracts from Capt Carter's diary on his fatal march from Karema are next given, with a summary of recent news respecting African exploration The remaining notes deal with M. Mushketof's ascent of the Zarafshan glacier, Russian explorations in Eastern and Western Siberia, surveys in Turkey, and an attempt to explore the affluents of the Rio Purûs.

MR. J BANTING ROGERS has devised and published a game which is likely to be of service not only as a really interesting amusement, but also as a means of acquiring a considerable knowledge of navigation and meteorology It is entitled the game of a "Voyage Round the World," and is played on a large board representing the ocean, suitably divided for counting by knots, and with hazards in the shape of cyclones, collisions, &c, which add excitement to the game The game is played by means of a number of small models of ships of various kinds, and cards in which the number of knots is marked within which the players may move. Logs are kept, watches appointed, and a captain of the watch to record distances, &c. Altogether it will be seen that in Mr Rogers's ingeniously devised game there are great possibilities both of amusement and instruction

TWO Danish Expeditions which have been carrying on scientific exploration in Greenland have returned to Copenhagen. One of them, under Lieut. Hammer, has been continuing the investigations into the movement of the mainland ice into the fjords and the formation of icebergs. In the course of the summer several previously unknown fjords were visited, and the western part of the island of Disko surveyed and mapped. The other expedition, under Lieut. Holm, was to explore several of the large ruins of former settlements in the district of Julianhaab and to obtain information on the population and condition of the east coast. Several extensive ruins were found, which must have been left quite 100 years ago, and of which the present natives know nothing. Among these ruins many objects of ethnological interest were found. The weather during the whole summer was rainy and cloudy; indeed people who have been many years in Greenland never knew of so rainy a summer.

WE believe there is some prospect of Mr. Joseph Thomson being engaged to lead an expedition from Sierra Leone towards Timbuctoo, mainly to establish trading relations between the English Colonies and the interior. It would be a pity should Mr. Thomson be compelled to become a mere trading caravan leader.

MAJOR SERPA PINTO's account of his remarkable journey, which is still unpublished, is to be called "How I crossed Africa," instead of "The King's Rifle."

THE following telegram has been received in St. Petersburg from Col. Prejevalsky:—"Have finished my travel. Rich collections: 2000 birds, many mammals, 1300 species of plants. Will be in St. Petersburg at the beginning of January"

AT the last meeting (November 17) of the Russian Geographical Society, Dr. Piasetzky read an interesting paper on China. He has very closely studied the character of the Chinese, their life, their moral principles, and the education of children. Dr. Piasetzky, who has travelled during several years in China, is the author of a very interesting Russian work in two volumes on that country. the work is illustrated with very good drawings, which represent "types" of Chinese towns, streets, dwellings, market-places, &c. At the same meeting the Society resolved to take part in the next Geographical Congress and Exhibition at Venice

BEFORE proceeding to Paris, as we mentioned last week, MM. Verminck, Zweifel, and Moustier were present at an enthusiastic meeting of the Marseilles Geographical Society, when the President, M. Rabaud, after a eulogistic address, presented them with medals for the part they respectively took in the expedition to the sources of the Niger

LIEUT. E. W PETLEY, of the Marine Survey of India, has lately drawn up some interesting notes on Marmagao (Goa), Portuguese India.

THE new *Bulletin* of the Antwerp Geographical Society contains an account of Mr Andrew Goldie's last journey in New Guinea, and some observations on artesian wells in the Sandwich Islands.

MR. TODD, the Government Astronomer at Adelaide, is to proceed next May to Port Darwin, in the Northern Territory, to determine by telegraph the difference of longitude between that place and Greenwich.

A RECENT telegram from the Austrian traveller Oscar Lenz states that he had reached Medina, Senegal, on November 2. Oscar Lenz penetrated to Timbuctoo from the north, and went thence by Bassikonon, Sokolo, Goumbon, Nioro, and Konniakany to Medina

HERR STIER, director of the Gymnasium in Zerbst, found, a short time ago, a detailed account of Vasco da Gama's second voyage to India It is drawn up by a Dutchman (who accompanied Vasco da Gama), and in his own tongue. Herr Stier has now published a German translation of it.

MR MUNDELLA ON EDUCATION IN SCIENCE

ON Friday last the Textile and Dyeing Departments of the Yorkshire College, Leeds, were formally opened, and at the dinner which followed the Right Hon. A J. Mundella, M.P., Vice-President of the Council, proposed the toast of the occasion:—"Success to Yorkshire College." His remarks in connection therewith are so significant, coming from our *de facto* Minister of Education, that we give them in full

There had not, he commenced by saying, been a more gratified spectator of the proceedings of that day than he was. There had been no one amongst them who had enjoyed more, if so much, the sense of satisfaction—he had almost said of triumph—that he had enjoyed that day Sixteen years ago when he was, like many of those present, a captain in the ranks of industry, he took some interest in the question of the application of science to the industries of this country. His attention had been called to it by the advantages he possessed of seeing what was being done in other countries. He saw the infancy of technical education abroad, and now he stood by its cradle at home. The School of Arts et Métiers in Paris was not by any means a new school, and it had done great things for French industry. There was no one who was acquainted with that school who would not endorse his remarks when he said that it had done marvellous things for French manufactures, and he had learned since he came to Leeds that we had some of its most distinguished scholars in this town He witnessed the beginning of technical instruction in Germany with the erection of the Polytechnic School of Zurich, and when he went to the members of the Chamber of Commerce of which he was

president, and told them what he had seen, the answer was that they had great doubts about the success of the experiment It was thought then that the practical place to give technical instruction and teach the application of science to industry was in the workshops. They had now satisfied themselves, however, that whilst they could not dispense with the practical experience of the workshops, there was something that gave value to that experience. Let them take the art of dyeing for example What was the old system of training in regard to it? The dyer did not then ascertain the properties of the articles with which he had to deal with that skill and accuracy with which the young men of Leeds were ascertaining them to day It used to be a bucketful of this, a shovelful of that, and a handful of the other. But the days of the old rule of thumb were numbered, and on standing at the cradle of the Yorkshire College he stood by the grave of the rule of thumb He had been greatly encouraged this week by his visit to Yorkshire. He came to it somewhat in a state of despondency not however with reference to elementary instruction, for the people of Yorkshire were doing wonders in that way, and in a few years hence this county would compare favourably in that respect with any part of the globe But he had been examining recently, not for the first but the tenth time, what was being done on the Continent in the way of technical education They had opened a good school in Leeds, but they must not flatter themselves They must not believe that the 25,000*l* which his friend Mr Denison had indicated was the sum wanted to complete the work. He had stood in an industrial town of 70,000 inhabitants, in which a single building that had been erected within the past three years solely for teaching science, as applied to industry, had cost 100,000*l*. He had stood in three or four such towns He had examined technical institutions in France, in Switzerland, and in the south and north and centre of Germany, and all he could say was, that not having examined these institutions critically for five years, he stood amazed and almost aghast at what he beheld He came home feeling that in the countries he had mentioned they had found the weak place in our armour, and had wounded us in our tender part, but what he had seen in Yorkshire within the last week had given him renewed confidence and courage He found, in addition to this splendid institution which had been opened to-day, that in the little town of Keighley—a very splendid little place—they were going to spend 5000*l* in a weaving-school, that the Clothworkers' Company of London were going to assist Bradford also, and he was told that in Huddersfield they had got 15,000*l* or 16,000*l*, that they had no longer to teach elementary instruction in their night-classes, but wanted to give scientific and technical instruction to their workmen, and wanted a school for Huddersfield Yesterday he stood by the grave of an eminent Yorkshireman who had done noble service to the teaching of science in Yorkshire—his friend Mr Mark Firth Would they not see that Yorkshire had many as worthy sons as Mr. Firth? Surely he was not the last man that would endow a college for science teaching There were men, he hoped, within the sound of his voice who would perpetuate their memory, and show some gratitude to the industry that had made them wealthy by endowing another wing of the College like the one they had seen to-day They must not believe that this was mere amateur work. This was not science teaching merely for the sake of scientific research, for arriving at scientific truth, or for giving intellectual culture. Those nations on the Continent who had produced such magnificent buildings, machinery, and apparatus to conduct this work were not doing so from sentimental reasons They were not doing it with the object simply of endowing scientific research, or to make great progress in any particular branch of science Their object was a very prosaic and a very practical one, and very full of self-interest. What they meant was to get industrial strength, which they believed was the real source of the wealth of their nation. The Yorkshire College was founded to supply instruction in those sciences which were applicable to the industrial arts. He might say as the result of his recent observations that France and Germany were conducting as active a competition with each other in this matter of arming for the industrial fight as any of the nations of the Continent of Europe were in their military armaments with a view to any catastrophe in future. But this was not a case in which Englishmen could look on with benevolent neutrality, because after all in this international fight they could not stand aloof, they could not remain neutral, for the blow, whenever it fell, would fall upon them. Rely upon it the success of the Science College of Yorkshire meant the success of Yorkshire itself They possessed great natural resources for which their Continental neighbours envied them They had in their immediate neighbourhood, in the mine, the coal and iron, they had in their people great vigour, great energy, and great inventive capacity; and they had also their old prestige. They had amongst them men of great wealth There was his friend Mr. Denison ready to provide them capital very freely—at a very moderate rate England, after all, was the great emporium as a depôt market for nearly all the raw material of the world To London came that Australian wool so many thousand bales of which were exported to their neighbours on the other side of the water, and then came back to them in a finished state for the consumption of their own population He was speaking from actual knowledge when he said that there was an enormous increase in the manufacture of dressed goods that could be well made in Yorkshire, that could be produced and sold in Yorkshire, and that were yet made abroad, but ought to be made at home He believed the step they were taking that day in opening the College was the very way to create that employment at home which at present was too much done abroad It had been said that the country gentlemen ought to assist in this movement. Lord Frederick Cavendish had come from a great and honourable house, and they all rejoiced in the wealth, ability, business capacity, sagacity, and liberality of that house. But what was it that had made these great houses and England wealthy? Was it not the value which had been added to the land by the success of the great manufactures? The success of the great houses of England was bound up in the success of the Yorkshire College and of other colleges like it Thus to the success of their manufactures they must look for the continued greatness of England in its dealings with nations in the future Why, they had but the same area of land now as they had when their population was only 10,000,000. They had 25,000,000 of people in England and Wales now, and they were multiplying at a rate which would soon double this number What was it that was to feed all these people but the success of their manufactures? If they were to hold their own they must not lose a point, they must not neglect a single opportunity, they must not rest content on their old prestige, but they must, as Englishmen, look the difficulty in the face, and, where weakness existed, strengthen themselves, and this weakness was to be found entirely in the question of education, which they had too long neglected. In asking them to drink success to the Yorkshire College, he was asking them practically to drink to themselves. If they wished perfect freedom to carry on this work, he was quite of the opinion of Lord Frederick Cavendish that they must adopt the newest methods—to be untrammelled in their efforts, to carry on the College by themselves, and in that way in which Englishmen had been accustomed to do their work

THE ROYAL SOCIETY—ADDRESS OF THE PRESIDENT[1]

II.

THE aspect of spectrum analysis has become much complicated by two sets of facts. First, the increased dispersion, the improved definition, the enlarged electrical power at our command, and, above all, the substitution of photography for eye observations, have revealed to us an almost overwhelming array of lines belonging to each substance And, secondly, the same means have shown that many substances present different spectra when in different molecular states. These complications have led spectroscopists to seek some relief in theories of simplification Lecoq de Boisbaudran, Stoney, Soret, and others have suggested that many of the lines, or groups of lines, may be regarded as the harmonics of a fundamental vibration, and they have shown that in certain cases this view will account for the phenomena observed Professors Liveing and Dewar have contributed largely to the subject by their observations on the reversed lines Looking in another direction, Mr. Lockyer considers that in increased temperature we have the means not only of resolving compound bodies into their elements, but even of dissociating bodies hitherto regarded as elementary into still more simple substances There still remain serious difficulties connected with Mr. Lockyer's views, but it is to be hoped that his indefatigable energy will in some way or other ultimately overcome them

The outlying parts of the spectrum, beyond the visible range,

[1] Address of William Spottiswoode, D C L, LL D, the President, delivered at the Anniversary Meeting of the Royal Society on Tuesday, November 30, 1880. Continued from p 114

must always be a subject of interest; and while MM. Cornu and Mascart, and others, have extended our knowledge of the ultra violet end, Major Abney has opened out to us a new region beyond the red. Lord Rayleigh and others before him have however proved that there must be a limit at the least refrangible end of the spectrum. Prof. Stokes, long since, noticed the difference in length between the spectrum of the sun and that of the electric arc, and M Cornu has recently shown by observations at elevated stations that the great rapidity of atmospheric absortion must preclude the hope of any great extension of the solar spectrum toward the more refrangible end.

The striking advances made in electricity during the last few years, and marked by, amongst other things, the inventions of the telephone and the microphone, have been followed by a step not less daring in its conception, nor less successful in its execution, I allude, of course, to the photophone, the result of the researches of Mr. Graham Bell and Mr. Sumner Tainter. The principle of this instrument is already known. A powerful beam of light is first thrown upon a flexible mirror, the curvature of which is modified through vibrations set up in it by the human voice. The reflected beam is then received by a selenium "cell" forming part of an electric circuit. The intensity of the light so received, and with it the resistance in the circuit due to the selenium, varies with the varying curvature of the flexible mirror. A large parabolic mirror is used at the distant station to concentrate the light on the selenium "cell"; and a telephone in the circuit reproduces the variations in the form of sound

Mr. Bell has however also shown that rays from the sun, or an electric lamp, when rendered intermittent by any convenient means, will set up in a plate of almost any substance vibrations corresponding to the intermittence. The substances as yet tried are: metals of various kinds, wood, india-rubber, ebonite, &c., and among them zinc appears to be one of the best suited for the purpose. This result, which is independent of any electric action, is perhaps due to heat rather than to light.

In these, as in many other issues of scientific research, we can hardly fail to be impressed by the almost inexhaustible resources which lie ready to hand, if we only knew how to use them, for the interpretation of nature or for the practical purposes of mankind.

During the past year Prof. Hughes employed his induction balance for the detection of very minute impurities in small masses of gold. Mr. Preece also has shown how slight increments of temperature in fine wires transmitting telephonic currents of electricity will suffice to reproduce sonorous vibrations, and even articulate speech, at a distant station by their influence on thin platinum wires only six inches in length.

Mr. Stroh has shown that, at the point of contact of two metals carrying strong electric currents, adhesion takes place, varying with the nature of the surfaces in contact, and that many of the effects at points of contact, previously attributed to induction, may be due to the peculiar action now for the first time brought under notice.

It is worthy of record that two Atlantic cables have been successfully laid during the present year; but that the operation has become so much a matter of course, that its occurrence has attracted little public attention. Two cables, each of more than 500 miles in length, have been laid across the Mediterranean, and the Cape Colony has been placed in telegraphic communication with this country by a cable of not less than 4400 miles.

Constant attention is paid in the General Post Office to the introduction of improved methods for the furtherance of the telegraphic communication throughout the country.

Steady progress has been made in bringing the electric light into practical use. The illumination of the Albert Dock of the London and St. Katherine's Dock Company, the Liverpool Street Station of the Great Eastern Railway, the St. Enoch's Station of the Glasgow and South Western Railway, and last, but not least, that of the reading-room of the British Museum, have become accomplished facts; while the City authorities have decided to extend the use of this light over various thoroughfares under their control. The subdivision of the light for domestic purposes is a problem which appears to have found a solution in the incandescent carbon lamp of Mr. Swan. Besides this, Mr. J. H. Gordon has devised, for the same purpose, a very ingenious application of rapid sparks from alternating machines, such as that of De Meritens, to produce incandescence in refractory metals. Lamps constructed on this principle completely fulfil the conditions of subdivision, but some difficulties of detail still retard their adoption for general use. There is, however, every reason to hope that the experience already gained, and the intelligence at present brought to bear upon it, will before long supply us with more than one form of domestic light.

The chief question of interest which has occupied the attention of the Iron and Steel Institute has been the adaptation of the "basic" process to the production of steel from pig metal containing a considerable percentage of phosphorus. Hitherto only pure hæmatite and spathic ironstones have been used for the production of steel; but it has now been shown that, by the employment of basic linings and basic slags, the metal is almost completely cleared of its phosphorus, and that steel of good quality may be produced from inferior ore.

The Conference on Lightning-Conductors, composed of delegates from the Royal Institute of British Architects, the Society of Telegraph Engineers, the Physical Society, and the Meteorological Council, is steadily pursuing its labours. A large mass of facts has been accumulated, several leading questions have been decided; and it is hoped that, in the course of the coming year, the Report of the Conference will be issued

One of the most interesting, and at the same time useful, applications of the dynamo-machines, is that of transmitting mechanical power to spots, or under circumstances, where the ordinary appliances cannot be conveniently used. Their principle will doubtless by degrees extend itself over a wide range of industry, especially in localities where water-power is abundant. A very remarkable instance of such adaptations will be found in Dr. Werner Siemens's propulsion of railway carriages in Berlin.

Our Fellow, Dr. C. W. Siemens in London, and M. De Méritens in Paris, have demonstrated the use of the high temperature of the electric arc in fusing refractory metals. The method of operation, while peculiarly convenient for laboratory purposes, and for demonstration, promises to be capable of extension, even to the large demands of commerce and manufacture.

I should not, moreover, omit mention of the very beautiful experiments by Dr. C. W. Siemens on the effect of the electric light on the growth of plants, on the opening of flowers, and on the ripening of fruit On this subject we hope to hear more hereafter. He has already commenced a fresh series of experiments, and contemplates continuing them during the coming winter.

I am not sure how far the fact is known to the Fellows of the Royal Society that the Society of Telegraph Engineers has thrown open to the scientific world a remarkable collection of books on electrical science, collected by our late Fellow, Sir Francis Ronalds, and bequeathed by him to that Society The catalogue, compiled by the collector, is a monument of concentrated and well-directed labour.

As regards the Transit of Venus in 1874, the printing of the observations is complete for the two groups of stations in the Sandwich Islands and Egypt, and that for others is in progress.

Preparations are already being made with a view to the observation of the Transit of Venus in 1882. As a preliminary step for this operation, as well as for general purposes, it had been decided that the longitude of the Cape Observatory should be definitively determined by telegraphic connection with Aden, which place is already telegraphically referred to Greenwich; and, notwithstanding a temporary interruption on the land line, Capetown-Durban, it may be hoped that the connection will be effected at no distant period. Mr. Gill is prepared to undertake the main share of the work. With the same objects in view, on the urgent representation of the Astronomer-Royal, it has also been determined to connect one of the Australian Observatories with Greenwich, through Madras, the longitude of which is well known; and this operation will be very much facilitated by the share which Mr. Todd, Government Astronomer and Superintendent of Telegraphs at Adelaide, would be prepared to take in it under the auspices of his Government. The eastern boundary of the Colony having been defined by Imperial Act as the 141st meridian, a wish has been expressed officially for the accurate connection of Adelaide with Greenwich, independently of the Transit of Venus.

The Astronomer-Royal has explained in detail the preparations which he considers necessary, so far at least as this country is concerned, for the effective observation of the transit, and he has introduced several alterations in the plan which he had formerly

suggested. The experience of the transit of 1874 points to the desirability of sacrificing something in the magnitude of the parallax-factor for the sake of securing a higher elevation of the sun; thus, for retarded ingress, Sir George Airy had at first proposed to refer principally to the coasts of the Canadian Dominion and the United States of North America, where the sun's elevation is from 15° to 18°, he now proposes to substitute for this the whole chain of West India Islands, from the eastern extremity of Cuba to Barbadoes, or stations on the neighbouring continent of Central America. Bermuda is also included as a favourable point for observation. Most, if not all, of the longitudes required have been determined with great precision by the Hydrographic Department of the United States. For ingress accelerated, Sir George Airy relies entirely upon stations in the Cape Colony. For the accelerated egress, all the stations suggested for ingress retarded will be available. For egress retarded, although the fixed Observatories at Melbourne and Sydney will contribute to the observation of the phenomenon, they will have the sun at a somewhat low elevation (10—14°), it is thereby proposed to rely mainly upon New Zealand, with which we are in telegraphic communication *viâ* Sydney. Considerable correspondence has taken place on the subject of Australian longitude, and it is expected that the necessary steps to effect the connection of one of the Observatories, probably Adelaide, with Madras, will be taken early in the ensuing year.

Sir G. B. Airy has completed the laborious calculations in his Numerical Lunar Theory, from which the corrections to the coefficients of Delaunay's Lunar Theory are to be deduced, and in connection with this work he has made an investigation of the value of the Moon's Secular Acceleration, for which he finally obtained the value 5″·477, thus confirming the results obtained by Prof. Adams, and subsequently by M. Delaunay. On this important question, Prof. Adams has also published an investigation (*Monthly Notices*, vol. xl. Nos. 6, 7, 8 and 9).

A new determination of the Physical Libration of the Moon from a large number of lunar photographs taken with the De La Rue reflector at the Oxford University Observatory has been recently made by Prof. Pritchard, the result being to indicate the existence of a small rotational inequality.

Messrs. J. Campbell and Neison have made use of the Greenwich Observations, 1862 to 1876, to determine the Lunar Parallactic Inequality, from which they deduce for the value of the Solar Parallax, 8″·778, or 8″·848, according as the existence of a forty-five year inequality, apparently indicated by the observations, is admitted or not (*Monthly Notices*, vol. xl. Nos. 7 and 8). The Sun's Parallax has also been determined by Mr. Downing, from N.P.D. observations of Mars at Leyden and Melbourne, in 1877. The value thus found is 8″·96 (*Astronomische Nachrichten*, No. 2288).

In continuation of his researches on tidal retardation from the action of a satellite on a viscous planet, Mr. G. H. Darwin has investigated the secular changes in the orbit of a satellite, deducing the early history of the earth and moon from the time when they were initially in contact, each revolving in the same period of from two to four hours. This leads to the suggestion that the moon was produced by the rupture of the primæval planet. In another memoir, Mr. G. H. Darwin gives analytical expressions for the history of a planet and a single satellite (*Phil. Trans.*, 1879, *Proc.* Roy. Soc., Nos. 200 and 202).

An important work in connexion with the United States Northern Boundary Commission has been published by Mr. Lewis Boss, on the Declination of Fixed Stars. The systematic corrections to some seventy catalogues have been discussed, and, from the mean of the whole, standard declinations of 500 stars have been deduced.

Dr. Gould's "Uranometria Argentina" and M. Houzeau's "Uranométrie Générale," are of especial value as giving important information on the brightness and distribution of the stars in the southern hemisphere.

Interesting results as to the diameters of satellites have been obtained by Prof. Pickering from photometric observations, on the assumption that their albedos do not differ greatly from those of their respective primaries. (*Annals*, Harvard College Observatory, vol. xi.) He has further investigated, on somewhat similar principles, the dimensions of the fixed stars, with especial reference to binaries and variables of the Algol type (*Proc.* Amer. Acad., vol. xvi.). Prof. Pickering has also commenced a photometric survey of the heavens, in which the brightness of every star visible to the naked eye is to be determined. He has further undertaken a search for planetary nebulæ by a new method, in which, by the use of a direct-vision prism in front of the eyepiece, the nebula is at once detected by its monochromatic spectrum, focussing a point of light instead of a coloured line as in the case of a star. About a hundred thousand stars have been examined, and four new planetary nebulæ have been detected. (*American Journal of Science*, October, 1880.)

From the grouping of the aphelia of certain periodic comets Prof. G. Forbes has inferred the existence of two ultra-Neptunian planets, and has indicated their approximate positions (*Trans.* Roy. Soc., Edinburgh.) Mr. D. P. Todd has deduced from the perturbation of Uranus a position for an ultra-Neptunian planet closely agreeing with that found by Prof. G. Forbes. So far, the search for the hypothetical planet with the 26-inch Washington refractor has been unsuccessful. (*American Journal of Science*, September, 1880.)

Prof. Bredichin's researches on the tails of comets have led him to the classification of these appendages according to the value of the solar repulsive force which would have generated them. Having discussed the forms of the tails of thirty-three comets, he finds that they belong to three types, corresponding respectively to repulsive forces 11, 1·4 and 0·3 (the sun's gravitation being taken as 1), and adopting Zollner's hypothesis of a repulsive force, due to electricity and inversely proportional to the specific gravity, he infers that the tails of the three types are composed respectively of hydrogen, carbon, and iron. In the case of the second and third types other elements of nearly the same atomic weight may replace or be mixed with the carbon and iron, and in such a comet as Donati's a number of substances may be mixed in the tail, which will consequently spread out in the plane of the orbit. The first type composed of hydrogen will always remain separated from the others. (*Annales* de l'Observatoire de Moscou, vols. iii. vi.)

The appearance, at the beginning of this year, of a great comet in the southern hemisphere, recalling by the length of its tail and the smallness of its head the remarkable comet of 1843, has excited great interest, more especially as it was found that the orbits of the two comets were sensibly the same. The observations of the comet of 1843, however, do not appear to be compatible with so short a period as thirty-seven years, and Prof. Oppolzer has shown that the action of a resisting medium would not meet the case (*Astronomische Nachrichten*, Nos. 2314, 2315). Under these circumstances Prof. D. Kirkwood has suggested that the two bodies may be fragments of one original comet, viz., that of 370 B.C., which is said to have separated into two parts like Biela's comet (*Observatory*, No. 43). Five other comets (including Faye's periodical comet) have been discovered this year, but two of them were lost through cloudy weather before a second observation could be obtained.

In astronomical physics Mr. Huggins has obtained photographs of stellar spectra, which establish the existence of a remarkable group of nine bands in the ultra-violet, probably due to hydrogen, and further lead him to an arrangement of the stars in a continuous series according to the breadth and marginal difference of the typical lines, particularly of the K line. Mr. Lockyer continues his researches on dissociation, as indicated in solar outbursts, and in connection with this work is engaged on a systematic observation of the spectra of sun spots. At the request of the Committee on Solar Physics, corresponding observations are being made at Greenwich.

From the series of Greenwich photographs of the sun, 1874—1879, the mean heliographic latitude of spots and mean distance from the sun's equator, have been deduced for each rotation and for each year ("Greenwich Spectroscopic and Photographic Results," 1879).

A fine 36-inch silver-on-glass reflector has been recently constructed by Mr. Common, and with this instrument he has obtained photographs of Jupiter, showing the red spot, and of the satellites (*Observatory*, No. 34).

At the outset of an undertaking one figures to oneself in imagination what may be done; towards the close of it one sees in actual fact what has been done. In commencing this address I had hoped to say something of the progress of mathematics; before bringing it to a conclusion I find my space filled and my time exhausted. How far the good intentions of this year may be realised in the next, cannot yet be seen; but the difficulties of a task do not always diminish the fascination of making an attempt.

THE ROYAL SOCIETY MEDALS

AT the conclusion of his anniversary address on Tuesday last week, the President, Mr Spottiswoode, delivered the medals which have been awarded this year, and in doing so spoke as follows :—

The Copley Medal has been awarded to Prof James Joseph Sylvester, F R.S. His extensive and profound researches in pure mathematics, especially his contributions to the Theory of Invariants and Covariants, to the Theory of Numbers, and to Modern Geometry, may be regarded as fully establishing Mr Sylvester's claim to the award of the Copley Medal.

One Royal Medal has been awarded to Prof Joseph Lister, F R S Mr Lister's claims to the honour of a Royal Medal are based upon his numerous and valuable contributions to physiological and biological science during the last thirty years

By permission of its author, the Fellow of the Society best qualified, by his own extensive researches on the germ theory, to form a judgment, I quote the following account of Prof Lister's work and achievements .—

"In 1836 and 1837 it was proved independently by Cagniard de la Tour and Schwann, that vinous fermentation was due to the growth and multiplication of a microscopic plant At the same time Schwann described experiments which illustrated and explained the conditions, now well known, by which flesh may be preserved from putrefaction But Schwann's researches were overshadowed by the views of accepted authorities, and they continued so up to the publication of Pasteur's investigations. From this point forward the view gained ground that putrefaction is the work of floating microscopic organisms ; and that if air be thoroughly cleansed of its suspended particles, neither its oxygen, nor any other gaseous constituent, is competent to provoke either fermentation or putrefaction.

"Condensed into a single sentence, the merit of Mr Lister consists in the generalisation, to living matter, of the results obtained by Schwann and Pasteur with dead matter. He began with cases of compound fracture and with abscesses In simple fracture the wound is internal, the uninjured skin forming a protecting envelope. Here nature works the cure after the proper setting of the injured parts In compound fracture, on the other hand, the wound extends to the surface, where it comes in contact with the air, and here the operator can never be sure that the most consummate skill will not be neutralised by subsequent putrefaction.

"In the earliest of his published communications Mr. Lister clearly enunciates, and illustrates by cases of a very impressive character, the scientific principles upon which the antiseptic system rests He refers to the researches of Pasteur, and shows their bearing upon surgery He points to the representative fact, then known but unexplained, that when a lung is wounded by a fractured rib, though the blood is copiously mixed with air, no inflammatory disturbance supervenes, while an external wound penetrating the chest, if it remains open, infallibly causes dangerous suppurative pleurisy. In the latter case the blood and serum are decomposed by the microscopic progeny of the germs which enter with the air; in the former case the air is filtered in the bronchial tubes, and all solid particles are arrested Three years subsequently this inference of Prof Lister was shown to be capable of experimental demonstration

"After enunciating the theoretic views which guided him, he thus expresses himself in his first paper —

"'Applying these principles to the treatment of compound fracture, bearing in mind that it is from the vitality of the atmospheric particles that all the mischief arises, it appears that all that is requisite is to dress the wound with some material capable of killing these sep ic germs, provided that any substance can be found reliable for this purpose, yet not too potent as a caustic'

"This is the thesis to the illustration and defence of which Prof. Lister has devoted himself for the last thirteen years. His thoughts and practice during this time have been in a state of growth. His insight has been progressive, and the improvement of experimental methods founded on that insight incessant. By contributions of a purely scientific character, which stamp their author as an accomplished experimenter, he has materially augmented our knowledge of the most minute forms of life. The titles of his papers indicate the direction of his labours from time to time; but they give no notion of the difficulties which he has encountered, and successfully overcome. He performs, without dread of evil consequences, the most dangerous operations He ventures fearlessly upon treatment which, prior to the introduction of his system, would have been regarded as no less than criminal. In the Glasgow Royal Infirmary, when wards adjacent to his had to be abandoned, he operated with success in an atmosphere of deadly infectiveness. Vividly realising the character and habits of the 'invisible enemy' with which he has to cope, his precautions are minute and severe. This demand for exactitude of manipulation has rendered the acceptance of the Antiseptic System slower than it would otherwise have been, but a clear theoretic conception has this value among others it renders pleasant a minuteness of precaution which would be intolerable were its reasons unknown.

"The operative surgeons of our day have raised their art to the highest pitch of efficiency. Their skill and daring are alike marvellous Mr Lister urges an extension of this skill from the operation to the subsequent treatment, contending that every surgeon ought to be so convinced of the greatness of the benefits within his reach as to be induced to devote to the dressing of wounds the same kind of thought and pains which he now devotes to the planning and execution of an operation. His impressive earnestness, his clearness of exposition; his philosophic grasp of the principles on which his practice is founded—above all his demonstrated success—have borne their natural fruit in securing for him the recognition and esteem of the best intellects of the age.

"In a letter addressed to the writer on the 29th of September, 1880, Prof Helmholtz expresses himself thus .—

"'Prof Lister ist als einer der hervorragendsten Wohlthäter der Menschheit zu betrachten, und als eines der glänzendsten Beispiele, wie segensreich scheinbar minutiöse und abstruse wissenschaftliche Untersuchungen, wie die über di Erzeugung mikroskopischer Organismen, werden können, wenn sie von einem Manne von umfassendem geistigen Gesichtskreise aufgenommen werden'"

"In a letter dated October 1st, 1880, Prof. Du Bois Raymond writes —

"'The period of bloody warfare through which we passed not long ago, just when Prof Lister's methods were matured enough to be freely used even on the battlefield, has of course contributed to render his name popular throughout Germany, nay, to make it a household word in many homes We use the word 'listern' as a verb to designate the use of the carbol-spray while bandaging a wound. I do not hesitate to proclaim Lister the greatest benefactor of mankind since Jenner's wonderful discovery—far superior, indeed, to Jackson and Simpson; because, whatever may be the dread of pain and the blessing of being spared it, in Lister's invention health and life itself are concerned, as in hardly any other medical discovery except vaccination. Moreover, the general ideas which have led to Prof Lister's conception stamp his work with a peculiarly scientific character'

"In a letter dated from Vevey on the 10th of this month, Prof. Klebs of Prague, himself a distinguished worker in this field, expresses in the strongest terms his admiration of the profound philosophical intuition and practical success of Mr. Lister, as having not only reformed the whole art of surgery, but given a new impulse to medical science generally Prof. Klebs's interpretation of the opposition encountered for a time by Mr. Lister is worthy of mention He ascribes it to the high standard attained by British surgery before the time of Lister. 'The operators,' he says, 'that work under the best hygienic conditions will not feel so acutely as others do the necessity of disinfecting wounds. But the good results of the former British surgery are now surpassed by the new method, which is accepted at the present time by the whole world.'

"Such testimonies might be multiplied to any extent. The foregoing are the answers received from the only three gentlemen who have been requested to express an opinion as to the merits of Mr. Lister."

The second Royal Medal has been awarded to Capt Andrew Noble, late R.A, F.R.S. Capt. Noble is joint author with Prof. Abel of the "Researches on Explosives," *Phil Trans*, 1875, which, in combination with other labours in the same field, procured for Prof. Abel the honour of the Royal Medal in 1879 To Prof. Abel is due mainly the chemical part of these investigations, to Capt. Noble the mechanical and mathematical part. Each is a complement of the other, but it

may be safely affirmed that they could not have been presented to the world in the form in which they appear without the co-operation of his remarkable union of technical knowledge and mastery of mathematical analysis with the chemical science of Prof. Abel. His beautiful invention of the Chronoscope, an instrument constructed by him at great cost, by which intervals of time as small as the one-millionth part of a second can be measured, has been of indispensable value in these researches He is the author of papers which have been translated into most European languages on subjects of gunnery and gunpowder, he is perhaps the highest authority we possess on the higher branches of artillery science, and the best known on the Continent His great talents and attainments are not more conspicuous than his singular modesty and his indefatigable industry. He has been engaged on these subjects about twenty years, having published the first experiments in this country with Navez' electroballistic apparatus, in 1862

The Rumford Medal has been awarded to Dr William Huggins, F R.S. In 1866 a Royal Medal was awarded to Dr. Huggins for his important researches. Since that time he has been continually engaged in prosecuting the subject of celestial spectroscopy, both in the departments in which he had already done so much, and in others of its branches. One subject of Dr Huggins' researches relates to the determination of the radial component of the velocity of the heavenly bodies relatively to our earth, by means of the alteration of the refrangibility of certain definite kinds of light which they emit, or which are stopped by their atmospheres The smallness of the alteration corresponding to a relative velocity comparable with the velocity of the earth in its orbit makes the determination a matter of extreme delicacy. But as early as 1868 he had obtained such trustworthy determinations that he was able to announce before the Royal Society in that year that Sirius was receding from our solar system with a velocity of about 29 94 miles per second.

In a paper presented to the Royal Society in 1872 he has given the results obtained for a large number of stars, and has shown that some are receding and some approaching, and that there seems to be a balance of recession in those parts of the heavens, from which we have reason, from the observed proper motions, which of course can only be transversal, to conclude that the solar system is receding, and a balance in favour of approach in the opposite direction, while yet it does not appear that the motion of the solar system would alone account for the whole of the proper motions of the stars in a radial direction

The same inquiry was extended to the nebulæ, the spectrum of which consists of bright lines, and in this case it presented greater difficulties As those nebular lines which appear pretty certainly to be identifiable with hydrogen are too faint to be employed in the investigation, and the others are not at present identified with those of any known element or compound, he was obliged to avail himself of a coincidence between the brightest nebular line and a line of lead But as the coincidence is probably merely fortuitous, the results give only the *differences* of approach or recess of different nebulæ. The observations seem to show that, so far as has been observed, the nebulæ are objects of greater fixity as regards motion in space, than the stars

The other subject to which Dr. Huggins has more particularly devoted himself of late, is the mapping of the photographic spectra of stars. This was a research of great delicacy, partly on account of the small quantity of light at the disposal of the observer, partly from the great accuracy with which the comparison had to be made with the spectra of known substances, in order that satisfactory conclusions should be deducible as to the presence or absence of such or such substances in the stars. The results obtained led to a remarkable division of the stars into two great classes, naturally with transition cases, namely, white stars, which showed a group of twelve dark lines belonging, apparently, to the same substance, probably hydrogen, and the group of stars, of which our own sun may be taken as a type.

Besides the researches already mentioned, other papers have been presented by Dr. Huggins to the Royal Society, on the spectra of comets, on the spectrum of Uranus; and in particular one in which he showed that it was possible to detect the heat of the stars, and has given the results obtained for several.

The Davy Medal has been awarded to Prof. Charles Friedel, Member of the Institute of France.

From 1856 to the present time the investigations of M Charles Friedel, ranging over widely-remote fields of chemical inquiry, have been continuous, numerous, and important. Mineralogical, theoretical, and general chemistry are indebted to him for many valuable contributions, but it is in the department of so-called organic chemistry that he has more especially laboured, and herein he has done much to assist in breaking down the barriers at one time regarded as impassably isolating the chemistry of carbon compounds.

Among the subjects of M Friedel's successful work may be mentioned more particularly the chemistry of the 3-carbon family of organic bodies, to which belong propionic acid, lactic acid, glycerine, propylene, and acetone. The establishment of the constitution of lactic acid and of acetone, with the determination of the relationships to one another of the various, and in many cases isomeric, members of this large family, constituted for a long time one of the most fiercely-contested, as it was, and is, one of the most fundamental problems of organic chemistry In the labours effecting the satisfactory solution of this problem M Friedel bore a large share.

Passing to another branch of investigation, M. Friedel, partly by himself, but largely in conjunction in some parts of the work with Mr J M Crafts, and in other parts with M A. Ladenburg, made out, or confirmed in a very striking manner, the analogy subsisting between the modes of combination of carbon and of silicon, the most characteristic elements of the organic and inorganic kingdoms respectively.

To mention but one more subject of M Friedel's research, he has, in conjunction with Mr J M. Crafts, made out and defined a simple method of wide application for effecting the synthesis of organic compounds. This method consists in bringing together a hydrocarbon and an organic chloride in presence of chloride of aluminum, whereby the residues of the two compounds enter into combination to form a more complex, frequently a highly complex, body Independently of its utility, this process of synthesis is of remarkable interest from the part taken in it by the chloride of aluminum, which, though essential to the reaction, is found unaltered at the end, and seems to act by suffering continuously, little by little, a correlative transformation and regeneration

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

OXFORD —The statutes made by the new Commissioners for the different colleges are appearing in their final shape. The statutes of six colleges are already printed and in the hands of Members of Convocation. They resemble each other closely in several respects Ordinary Fellows are to be elected by examination, all the branches of learning recognised in the final schools of the University being taken from time to time as the subject of examination. These Fellowships are tenable for seven years Tutorial Fellows are elected without examination, but the colleges may require two years' college work from an ordinary Fellow, having given notice of such requirement before the examination The colleges may elect persons distinguished in literary or scientific work to Fellowships tenable for a term of years, during which the Fellows shall devote themselves to a definite research specified in the resolution appointing them

Several meetings of the Professors and College Tutors engaged in teaching different branches of Physics in the University have been held during the last fortnight at the instance of Prof. Clifton. The object was to prepare a scheme of lectures for next term, such that the lecturers would cover most of the ground without clashing with each other or with the lecturers in other branches of science It may be mentioned that this is the first time such an arrangement has been arrived at in the Natural Science School at Oxford The following plan of lectures has been agreed upon for next Lent Term —

Optics (treated Mathematically), Prof Price, Tuesday, Thursday, and Saturday, at 12; Magnetism (treated experimentally), Prof Clifton, Wednesday and Saturday, at 12, Practical Physics, Prof. Clifton, Mr. Stocker, Mr. Jones, daily, 11 a.m. to 4 p m Thermodynamics and Electrodynamics (treated mathematically), Mr. Baynes, Monday, Wednesday, and Friday, at 10, Electrostatics (treated mathematically), Mr. Hayes, Saturday at 11; Elementary Mechanics (treated experimentally), Mr. Stocker, Monday and Wednesday, at 10; Problems in Elementary Mechanics and Physics, Mr. Jones, Friday, at 10; Elementary Physics (treated experimentally), Mr. Dixon, Monday, Wednes-

day, and Friday, at 11. The last three courses of lectures are intended to meet the requirements of candidates for the Preliminary Honour Examination.

SOCIETIES AND ACADEMIES

London

Geological Society, November 17.—Robert Etheridge, F.R.S., president, in the chair —Prof. Joseph Henry Thompson, Auckland, New Zealand, was elected a Fellow of the Society —The President called attention to the portrait of Dr. William Smith, presented to the Society by his grand-nephew, Mr. W. Smith of Cheltenham, which was then suspended behind the chair, and expressed his great satisfaction at this most interesting picture being in possession of the Society. Mr. W. W Smyth expressed the satisfaction which all must feel in possessing a genuine relic of this eminent stratigraphical geologist Now this one, which had been so liberally presented to the Society, was a most indubitable portrait of the most conspicuous founder of English geology. That portrait was painted by M. Fouran in 1837, and was certainly an admirable likeness. The Society was deeply indebted to the donor, Mr. W Smith, the cousin of the valued Prof. Phillips. The portrait now hanging on the wall was engraved in Prof. Phillips' "Life" of his uncle. He proposed a hearty vote of thanks to the donor Mr. Evans rose with great pleasure to second the vote of thanks proposed by Mr. Warington Smyth. The portrait was indeed replete with interest, not only to English geologists, but to all geologists in the world. An additional interest attaching to the portrait was that we had the whole history of it from Dr. Smith's own hand, an extract from which Mr Evans read The portrait was an admirable one. He hoped that in the future Mr. Smith's example would be followed, and that we should see many other portraits of eminent geologists on the Society's walls. The Society was also deeply indebted to the president for the interest which he had taken in the matter. The vote of thanks was carried by acclamation.—The following communications were read :—On abnormal geological deposits in the Bristol district, by Charles Moore, F G S.—Interglacial deposits of West Cumberland and North Lancashire, by J. D. Kendall, C.E., F G S

Royal Microscopical Society, November 10.—Dr. Beale, F R S, president, in the chair —Photographs of *P angulatum* and *Frustulia saxonica* were exhibited by Herr O. Brandt, the Tolles-Blackham and eight other microscopes by Mr Crisp, "Calotte" diaphragms by Mr. Swift; Hyde's illuminator by Mr J Mayall, jun.; and Dr Carpenter, C B., described Wale's "working microscope" with Iris diaphragm, which he highly commended as combining many novel and excellent points for a student's microscope.—Mr. Lettsom described Abbe's "stereoscopic ocular," and Dr Maddox his apparatus for collecting particles from the air.—Notes were read on monobromide of naphthaline (for mounting diatoms to increase their "index of visibility").—On ebonite for microscopical appliances, and on aperture exceeding 180° in air, also papers by Mr Stewart on the echinometridæ, and by Dr. Royston Pigott on testing object glasses.

Paris

Academy of Sciences, November 22.—M. Edm Becquerel in the chair.—The following papers were read:—Meridian observations of small planets at the Greenwich and Paris Observatories, communicated by M. Mouchez —The thermal springs of the coast chain of Venezuela (South America), by M. Boussingault. The most important are those of Onoto (alt. 696 m.), Mariara (533m), and Trincheras, near Nueva Valencia (300 to 350m.) The respective temperatures are 44°·5, 64° 0, and 96° 9, showing an increase proportional to the decrease in altitude, 1° for a difference of level of 6m. to 7m. After the springs of Urijino, Japan (100°), those of Trincheras are probably the hottest. The author gives an analysis of their water; also general descriptions of the others —*Reconnaissance* of the Napo (Equatorial America), by M. de Lesseps. This important affluent of the Amazon has been scientifically explored by M. Wiener, who in seven months has crossed South America in its greatest width, Quito to Para. The river is navigable a thousand miles from its entrance to the Amazon. He indicates a region larger than France well suited for colonisation.—On the treatment of vines with sulphide of carbon, by M. de Lafitte. —On the simultaneous reduction of a quadratic form and of a linear form, by M. Poincaré.—On Leverrier's tables of the motion of Saturn, by M. Gaillot.—On a property of the polynômes X_n of Legendre, by M. Laguerre —New tables for calculating heights by means of barometric observations, by M. Angot These tables give directly the height of each station above the level where the pressure is 760mm.; this is near the true altitude, an idea of which may thus be had without comparing results from two stations The exactness is at least as great as with the best formulæ proposed. The heights calculated differ always from the real height in a sense that can be known *à priori*.—Researches on sulphide of nitrogen, by M. Demarcay. —On phytolaccic acid, by M. Terreil. This new organic acid exists in the state of a salt of potash in the fruit of *Phytolacca Kæmpferi* (Its properties are described.)—Measurement of the toxical dose of carbonic oxide in different animals, by M. Gréhant. Great differences were observed: a mixture of $\frac{1}{800}$ strength was the poisonous dose for one dog, $\frac{1}{300}$ for another (the animals being made to breathe 200 litres). A rabbit required $\frac{1}{70}$ (breathing 50 litres). The smallest sufficing dose was that for a sparrow, $\frac{1}{4000}$.—On a new species of *Poroxylon*, by M. Renault This plant is named *P. Edwardsii*. The *Poroxyleæ* are found in the Upper Coal and Permian formations.—Transformation of a fructiferous ramification, resulting from fertilisation, into a prothalliform vegetation, by M. Sirodot. This was observed in *Batrachospermum vagum* (Roth).—Influence of light on the respiration of seeds during germination, by M. Pauchon These experiments were made on the castor-oil plant (as being oleaginous and albuminous) and on the haricot bean (feculent and without albumen). As in previous experiments, a good deal more O was observed in light than in darkness The castor-oil seeds exhale slightly more CO_2 in darkness than in light, but the opposite was the case with the seed of *Phaseolus* In darkness the ratio of CO_2 to O was for the haricot at least $\frac{1}{8}$ superior to that for the castor oil plant, but prolongation of the experiment tends to bring the relation equal to unity, whatever the original value. For a given quantity of oxygen absorbed the seed placed in darkness exhales more CO_2 than that kept in light. While in light there is always less CO_2 exhaled than O absorbed, the contrary occurs in darkness. These facts explain the transformation of legumin into asparagin. —Observations on the *rôle* attributed to maize, used as food, in the production of pellagra, by M. Fua. He considers M Faye's opinion, that pellagra may be caused by the large use of unfermented maize, to be in contradiction with facts. Maize is always eaten in the unfermented state. It forms the chief food of a large population in Central Africa, where pellagra does not occur, and similarly in Naples and in Hungary. He refers to certain alterations of maize (by fungi and oxidation).

Vienna

Imperial Academy of Sciences, December 2. Dr. L. A. Fitzinger in the chair.—On the theory of so-called electric expansion or electrostriction, Part ii., by Dr Boltzmann —Calculation of the absolute value and determination of the general equation of electrostriction, by the same.—On some properties of bromide of ammonium, by Dr Eder —Observations on contact-electricity (sealed packet), by Herr Schulze-Berge —Results of an investigation of the identity of the comets 1880 *e* and 1869 III, by Herr Zelber and Dr. Heppeiger —On graphic formula of hydrocarbons with condensed benzol-nuclei, by Herr Wegscheider.

THE CHEMISTRY OF THE FUTURE

Ideal Chemistry. By Sir B. C. Brodie, Bart., D.C.L., F.R.S. A Reprint of a Lecture delivered before the Chemical Society on June 6, 1867. (London: Macmillan and Co., 1880.)

CHEMISTS who wish to study the "Calculus of Chemical Operations" will value this reprint of the lecture delivered by Sir Benjamin Brodie shortly after presenting his first memoir on the subject to the Royal Society, as it is in the main devoted to the description and explanation of the special symbols employed in the Calculus.

Even if this were the time and place, I should not venture to submit Sir Benjamin Brodie's views to that exhaustive analysis, which I believe has hitherto never been accorded to them, but which they must ere long receive at the hands of chemists. As yet only portions of the Calculus have been published, viz., Part I. "On the Construction of Chemical Symbols," and Part II. "On the Analysis of Chemical Events," although a valuable supplementary explanation of certain features was recently elicited by Naquet's criticisms. We have still to learn how the author proposed to treat of isomerism, by far the most intricate and difficult problem yet to be solved in chemistry, and let us hope that his departure from amongst us, which we now deeply lament, may not involve the suspension of judgment on this point he asked for but a short time ago being for ever.

I cannot refrain from devoting this notice to specially directing attention to what appears to me to be the topic of fundamental importance in the lecture, viz. the suggestion, made the author believes for the first time excepting in a few words at the conclusion of his first Memoir in the *Philosophical Transactions*, of the possible decomposition at the elevated temperature of the sun of certain chemical elements.

The fundamental hypothesis of the Calculus is to express the symbol of the unit of hydrogen by one letter, a. Hydrogen is to be regarded as constructed at once, by one operation. But while hydrogen is conceived of as the product of a single operation, the hypothesis indicates that oxygen, ξ^1, cannot be conceived of as made by less than two operations, while chlorine, $a\chi^2$, and nitrogen, $a\nu^3$, for example, are each to be conceived of as made by three operations, one operation in each case being that by which hydrogen is made. In short, the hypothesis involves the conclusion that there are several distinct classes—three at least—of "elements," of which hydrogen, oxygen and chlorine are the types, formed respectively by a single operation, by two similar operations, and by several operations not all similar. In other words, to quote the author, "we are led to a certain physical hypothesis as to the origin and causes of chemical phenomena." He then continues:—

"Now what I am going to suggest you must consider to be put before you with reservation, but we may conceive that in remote time, or in remote space, there did exist formerly, or do exist now, certain simpler forms of matter than we find on the surface of our globe—a, χ, ξ, ν, and so on—I say we may at least conceive of, or imagine, the existence in time and space of these simpler forms of being, of which we have some records remaining to us in such elements as hydrogen and mercury. We may consider that in remote ages the temperature of matter was much higher than it is now, and that these other things existed then in the state of perfect gases—separable existences—uncombined. This is the farthest barrier to which in the way of analysis theory can reach. Beyond all is conjecture. There may be something further, but if so, we have no suspicion of it from the facts of the science. We may then conceive that the temperature began to fall and these things to combine with one another and to enter into new forms of existence, appropriate to the circumstances in which they were placed. We may suppose that at this time water ($a\xi$), hydrochloric acid ($a\chi$), and many other bodies began to exist. We may further consider that as the temperature went on falling, certain forms of matter became more permanent and more stable, to the exclusion of other forms. We have evidence on the surface of our globe of the permanence of certain forms of matter to the exclusion of others. We may conceive of this process of the lowering of temperature going on so that these substances, $a\chi^2$ and $a\nu^3$, when once formed, could never be decomposed—in fact, that the resolution of these bodies into their component elements could never occur again. You would then have something of our present system of things."

We have here a most distinct prior statement by Sir Benjamin Brodie of views almost identical with those which have been so persistently urged for several years past by Mr. Lockyer, whose arguments, however, have hitherto met with but little sympathy from chemists, mainly perhaps on account of the unwonted character of the evidence. In his paper read before the Royal Society in December 1878, Mr. Lockyer adduced two lines of evidence in support of his hypothesis of elemental dissociation at high temperatures. The existence of lines common to several spectra—so-called basic lines—and the progressive alteration in the character of the spectra of the stars with temperature. Neither of these lines of argument has, I believe, yet been impugned, and the criticisms launched against the hypothesis have been on side issues of no real importance to the main question under discussion. More recently additional evidence in the same direction has been obtained by the comparison of the observations of Tacchini and others on solar storms. It appears that whereas at certain times lines which are admittedly all iron lines are visible, at other times certain of these lines are wanting from the spectrum, new lines appearing in their place: fluctuations of this kind taking place at frequent intervals, but evidently in accordance with some well-defined law. Facts such as these may after all meet with some other interpretation than that furnished by the "dissociation" hypothesis, although at present this affords by far the simplest explanation of them. A communication of Mr. Lockyer's, read at the last meeting but one of the Royal Society, however, adduces evidence which if confirmed must, it would seem, be regarded as final. It is well known that the velocity of uprush or downrush of vapours at the sun may be determined by observations of the amount of displacement from their normal position of the lines in the spectrum of the vapours, and obviously if all the lines in a given spectrum—that of iron, for instance—are lines due to one substance, it must be a matter of indifference by which of the lines the velocity is measured. Whereas, on the other hand, if this be not the case, and the simpler substances into which the body

is split up be of different degrees of volatility—of different molecular weight—we may expect that measurements of the displacement of different lines will not all furnish the same results. Mr. Lockyer states that in an observation of a sun-spot on August 31 of this year, when the iron line at λ 5207 6 was doubly contorted, indicating an ascending and descending velocity of about fifteen miles a second, the two adjacent iron lines at λ 5203 7 and 5201 6, visible in the same field of view, were perfectly steady Observations of this kind are necessarily very difficult, and the communication is made with all reserve; but it is to be hoped that observers elsewhere will co-operate in at once putting this observation to the test

It is difficult to exaggerate the importance of the question to the chemistry of the future, for should it once be proved that the dissociation of the so-called elements is taking place in the sun and still hotter stars, it will be within the power of the physicist with the aid of the telespectroscope to build up a theory of elemental evolution not inferior in interest to the doctrine of organic evolution For my part, I have no fear of the result, for apart from Sir Benjamin Brodie's hypothesis and apart from spectroscopic evidence, I believe that in the relations of the "elements" to each other when arranged more or less in accordance with the now well-known periodic law of Mendeljeff we have distinct proof of progressive development, but of this I hope to say more on another occasion.

Sir B Brodie points out in his lecture that if the symbol α'^2 were assigned to hydrogen, instead of the symbol α, a different symbolic system analogous in its form to the system in vogue amongst chemists would result In the second part of the Calculus he has fully explained his reasons for adopting the hypothesis α, notwithstanding that it leads to conclusions so entirely different from those ordinarily accepted, the chief reason being that this hypothesis satisfies the so-called law of even numbers—the law that the sum of all the units of affinity in a compound is an even number The recent remarkable discovery—probably one of the most important theoretically ever made by chemists—of the behaviour of the halogens at high temperatures would appear to furnish an opportunity of experimentally ascertaining whether Sir B Brodie's hypothesis α is admissible, for this hypothesis would not admit of a simple resolution of the diatomic molecules of chlorine, bromine and iodine into monatomic molecules which has been regarded as the more probable explanation of the results obtained by Victor Meyer and by Meier and Crafts. Two well-established exceptions to the law of even numbers exist, nitric oxide, NO, and nitric peroxide, NO_2, but as is well known, Sir B. Brodie has suggested that in these we may not be dealing with homogeneous gases, but that each is constituted of two gases which, taken together, are made up of oxygen and nitrogen, but which separately are not so made up: hypothesis α would lead to similar conclusions regarding the constitution of chlorine, bromine and iodine at high temperatures

At present all that is *established*, however, regarding the halogens is that iodine begins to undergo dissociation at a temperature between 600° and 700°, and that its vapour gradually diminishes in density until at a white heat it attains not far short of half the "normal" value. Whatever the nature of the dissociation products, the occurrence of dissociation must be regarded as *placed beyond doubt*, for Victor Meyer's results have been in the main confirmed not only by Meier and Crafts, but also by Deville and Troost, who had previously obtained normal results Bromine does not undergo dissociation so readily as iodine, the ratio of the observed to the theoretical "normal" density being, according to Meier and Crafts, ·8 for bromine when it is 66 for iodine. In a recent communication, Victor Meyer has stated that the results of his earlier experiments with chlorine would appear to have been vitiated by some as yet undiscovered source of error; this gas probably is not dissociated except at extremely high temperatures, and it is doubtful whether there is any difference in behaviour between free and nascent chlorine

HENRY E ARMSTRONG

HANDBOOK OF BOTANY

Handbuch der allgemeinen Botanik Von Prof Dr. N J C Muller Zweiter Theil Allgemeine Morphologie und Entwickelungslehre der Gewachse Pp 482, Figs 277 (Heidelberg, 1880 Carl Winter's Universitatsbuchhandlung)

THIS is the second instalment of a work by a single author which is to treat of all the different departments of botanical science The first volume, which is devoted to the consideration of the Physiology and General Anatomy of Plants, was reviewed in NATURE, vol xxi p 589 It is impossible to pass a more favourable verdict upon this volume than upon its predecessor It is characterised by the same failing, namely, a want of clearness and definiteness in the statement of important facts and fundamental principles. The first section of the book is devoted to a discussion of the theory of descent, the origin of species, and the occurrence of varieties and monstrosities, with the object, presumably, of making the reader acquainted with some, at least, of the influences which determine the forms of living organisms. The account of the morphology of plants begins at p 38, and after ten pages of general considerations the subject is actually grappled with. Prof Muller commences with the Thallophytes, though he does not call them so, for his first section on them is headed "Der Algenstamm" It is not easy to understand what he means by the suffix "stamm", does he mean to describe the thallus of the Alga as being a "stem," or does he use the word in the sense of "tribe"? Whichever be the true interpretation, it still remains unexplained why this word should appear as the heading of a section which treats not only of Algæ, but of Fungi as well. The prospectus of the work sets forth that the Classification of Plants is to form the subject of a subsequent volume, and there is therefore some hope that Prof. Muller will there give a classification of the Algæ which is more in accordance with facts and with reason than the one which he now follows. It is impossible to imagine on what grounds the Palmelleæ, the Protococcæ, and the Volvocineæ should be united together to form the Order Palmellaceæ, and yet this is done on p 51 of this work, although the author is evidently aware of the fact that in Volvox reproduction is effected by means of sexually produced oospores, as his account of that plant, a singularly inaccurate one be it said, on p. 62 testifies.

His account of the Lichens is not more trustworthy than that which he gives of Volvox He appears to be halting between two opinions with regard to the burning question of the nature of these organisms, for although he states on p. 69 that the germinating spore gives rise to both gonidia and hyphæ, thereby implying that those cells of the thallus which do not contain chlorophyll and those which do have a common origin, yet he admits (p. 74) that the gonidia may escape from the thallus and lead an independent existence, and further (p 84), that he has observed the formation of a lichen-thallus by the combination of algal and fungal forms which were originally distinct.

His treatment of the Cormophytes is also disappointing If the student, anxious to become acquainted with the most recent views as to such important points as the gymnosperms of the Conifers and the morphological significance of the embryo-sac and its contents in Flowering Plants, turns to the sections of this book which profess to treat of them, he will find only a few dogmatic statements with regard to the former point, and none at all with regard to the latter. Perhaps these points may have been thought too recondite for discussion in a work which professes to be a handbook for learners of the science, but many pages are devoted to the consideration of subjects, such as the more complicated forms of phyllotaxis, which have principally a mathematical interest Again, the morphology of the stem, of the leaf, and especially of the root, is dismissed far too summarily. It is to be hoped that these organs, as well as inflorescences, flowers, and fruits, will have justice done to them in the volume on the Classification of Flowering Plants. One further shortcoming must yet be mentioned, namely, the scantiness of the account given of the embryology of plants This is a subject which has been much studied in recent years, and, from the title of this book, it might naturally be expected that it would give a satisfactory account of the results which have been attained This is, unfortunately, by no means the case. Some of the facts are mentioned, it is true, but they are stated too briefly to be very intelligible, and no attempt seems to have been made to connect them together and to explain their significance.

It must be admitted that the book contains a considerable amount of information scattered through its pages, but the purely theoretical principles upon which this information has been arranged render it difficult of acquirement, and for this reason, if for no other, the book is not one which can be recommended for the use of students

OUR BOOK SHELF

The Gardens of the Sun, or, A Naturalist's Journal on the Mountains and in the Forests and Swamps of Borneo and the Sulu Archipelago. By F. W. Burbidge (London. John Murray, 1880)

THIS book is the itinerary of a competent and enthusiastic botanist, whose main object was "the collection and introduction of beautiful new plants to the Veitchian collection at Chelsea," in which he so far succeeded as to add about fifty ferns to the list of those already collected in Borneo, about twenty being also new to science, and to introduce alive the giant pitcher-plant of Kina Balu (*Nepenthes Rajah*, Hook. f.). But these alone by no means show the floral riches which have induced the author to use the by no means exaggerated term "Gardens of the Sun." Amongst epiphytal orchids which here growing in mid-air "screened from the sun by a leafy canopy, deluged with rains for half the year or more at least, and fanned by the cool sea-breezes or monsoons," is found the beautiful *Phalænopsis grandiflora*; nor in the mountain vegetation are like floral riches absent, at 5000 feet the curious pitcher-plant, *Nepenthes Lowi*, was found epiphytal on mossy trunks and branches, and higher still a "large-flowered rhododendron, bearing rich orange flowers two inches in diameter, and twenty flowers in a cluster" The forests and gardens of Borneo are equally rich in native and naturalised kinds of edible fruits, the mango, pine-apple, durian, rambutan, &c, being all alike plentiful and luxuriant, and, as Mr Burbidge remarks, in some favoured districts in Malaya the forests almost become orchards on a large scale, so plentifully are they stocked

Zoology was naturally less followed than botany, but still a collection of birds was made, notices of which, contributed by Mr. Sharpe to the Zoological Society, are appended to the volume. We however regret to find the word "alligator" still constantly occurring, whilst the word "boa" is equally misleading. Crocodile and python are words which do not seem to find a home in the East, nor moreover in many books of Eastern travel It is also quite erroneous to say that Borneo "is the only habitat of the wild elephant in the Malay Archipelago"; certainly so, at least, if we are not to exclude Sumatra from that region

Many ethnological facts are scattered about the volume; the account of the Jakuns of Johore is taken and fully acknowledged from Maclay's memoir on the subject in the "Journal of Eastern Asia", but the author contributes an interesting account of the method pursued by the Kadyans in playing the game of football No one but the student of games knows how difficult it is to find much or any information on this point in most books of travel

Tasmanian Friends and Foes Feathered, Furred, and Finned By Louisa Anne Meredith, Author of "My Home in Tasmania," &c With Coloured Plates from Drawings by the Author, and other Illustrations (London. Marcus Ward and Co, 1880)

IT will probably be granted that there is developed in most people a fondness for certain of what we are pleased to call the lower forms of animals Such are made pets of for various reasons the sweetness of their song, the brightness of their plumage, the splendour of their scales —these phenomena act as causes that attract the senses Their sometimes fond and gentle ways make of some, prime favourites, while a sense of their usefulness makes again of others indispensable companions to man.

Most of man's dumb companions have been taken from groups of animals with a more or less world-wide distribution, and it will no doubt be new to some of our readers to learn that in Australia—a country where the aborigines, for want of native pets, had to import at some time or another a dog—that there, such forms as brush kangaroos, wombats, bandicoots, and even great forest kangaroos—animals only known in these parts--can also become nice, quite gentle, mannerly things, doing a little damage now and then, it is true, by leaving long dirty tracks to bother the housemaid, like a boy home at Christmas time, or pulling up tulip-bulbs, or, worst of all, getting into the children's beds because they are comfortable. The beautifully got-up volume whose title heads this notice is written by a well-known and respected lady who has often before written pleasantly about her Tasmanian home and the bush friends she found or made there. In the present volume she writes an able defence of some of her dumb "marsupial" acquaintances, showing that

they too have intelligence, and that they exhibit at times a very respectable amount of common sense. The stories about them are strictly true, and from their very nature strictly new. But the volume tells also of many a two-footed friend, and the last few chapters almost exclusively treat of the fishes of the coast. There is much in this portion of the volume of interest to the scientific worker; there is much in every part of it to make it of value to those who care to learn something of the habits of Tasmanian beasts, birds, and fishes One feature of the volume must be specially noticed—the eight coloured drawings, excellently chromolithographed from the water-colour drawings of the author. From a personal knowledge of the splendid colouring often present in freshly-caught tropical fishes, these plates are, we should say, by no means too brilliant. Four are devoted to some of the strange, wondrously-coloured fishes, and four to flowers, fruits, and insects.

This volume would be an excellent and not over-expensive Christmas present, which may lie on any table however select, and be read by any person however critical.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.*]

The Editor urgently requests correspondents to keep their letters as short as possible. The pressure on his space is so great that it is impossible otherwise to ensure the appearance even of communications containing interesting and novel facts.]

Mr. Spencer and Prof. Tait

Prof. Tait's explanation itself shows that the word commonly applied to products of imagination, was applicable to his statements, for the only justification he assigns is that he "assumed," that is to say, imagined, that his substitution of "definition" for "formula" must have been the ground of offence How inadequate a plea this is, will be seen on re-reading the questions I put, which were these:—

"He [Prof Tait] says that because he has used the word 'definition' instead of 'formula,' he has incurred my 'sore displeasure and grave censure.' In what place have I expressed or implied displeasure or censure in relation to this substitution of terms? Alleging that I have an obvious motive for calling it a 'formula,' he says I am 'indignant at its being called a *definition*.' I wish to see the words in which I have expressed my indignation, and shall be glad if Prof. Tait will quote them He says:—'It seems I should have called him the *discoverer of the formula!*' instead of 'the inventor of the definition.' Will he oblige me by pointing out where I have used either the one phrase or the other?"

Every reader would infer that, for these specific statements made by Prof. Tait, there are specific foundations, which could be named when asked for. He does not name them, for the sufficient reason that they do not exist Unable, as he says, to see in the passages I quoted from him, anything else to call for "censure" (a strange inability!), he "of course" assumed that this change of terms was the ground of censure And the assumption thus made, is the only warrant he assigns for these positive assertions.

This is not all, however. Prof. Tait says:—"I could not have ventured to suppose that Mr. Spencer '*did not even know that he was in the habit of saying formula rather than definition*' This naive confession cannot but be correct." Of Prof. Tait's motive for putting this statement of mine in italics and calling it *naive*, the reader may judge for himself. How entirely correct it is, and how well Prof. Tait might have "ventured to suppose" it, will quickly appear. For there is proof that I am *not* in the habit of always saying formula rather than definition, and Prof. Tait had the proof before him. In the note on page 565 of the Appendix forming the pamphlet in question—a page which Prof. Tait must have read, since it concerns Mr. Kirkman and himself—I have used the word "definition." So that not only had Prof. Tait no evidence on which to base his distinct statements, but there was under his eyes positive evidence which negatived them.

Very possibly it will be said that the question about my uses of these words is a trivial one But this is not the question. The question is whether it is allowable to make an opponent look absurd by ascribing to him, in a quite positive way, things which he has neither said nor implied; and that, too, when he has implied the contrary. HERBERT SPENCER

Criterion of Reality

Will you kindly allow a learner to ask for the criterion according to which Kinetic Energy and Work are real things, while Momentum and Force are unreal? Prof. Tait says $\frac{1}{2}mv^2$ and *wh* express real things, but *mv* and *wt* unrealities (NATURE, vol xxiii. p 82)

If *wt* be "as unreal as is the product of a quart into an acre," how is it that *wh* is real? The illustration of quart and acre is as applicable or inapplicable to the one as to the other. In both cases we take the product of two numbers, not two concrete magnitudes, which of course it would be absurd to speak of multiplying together. In one case the product is the number of units of Momentum, in the other case it is the number of units of Kinetic Energy. If it be said that a thing is real if its quantity cannot be altered, and *vice versâ*, why is mv^2 said to be real, and *mv* unreal? They vanish together When Prof Tait asserts "there is no such *thing* as Force," "it is merely a convenient expression for a certain *rate*" (NATURE, vol. xiv p 459), he seems, if I may venture to say so, to confound the measure of Force with Force itself, and to lay himself open to Mr Spencer's comment that "a relation changes the state of a body." Certainly *mv* is not a *thing*, but neither is mv^2 a thing: yet the latter is the measure of something which Prof. Tait asserts to be "as real as matter itself": why is not that of which the former is the measure equally real? E G.

Bardsea

[What Prof Tait asserts may be correct or not, but it is self-consistent. He asserts in his lecture on "Force" (NATURE, vol. xiv. p 462) that matter and energy must be looked on as real things, *because we cannot change the amount of either*. Such expressions as $\frac{1}{2}mv^2$, and *wh*, are to be considered as *wholes*, not as products of two or more factors This separation into factors (where one is *mv*, or *w*, for instance) he asserts to be a relic of the old erroneous belief in the trustworthiness of the impressions made on the "muscular" sense.—Ed.]

Landslips

In NATURE, vol. xxii. p. 560, I pointed out that landslips often occurred in the Salt Districts. I did not then expect that I should so soon be able to refer again to the subject, but on December 6, at an early hour in the morning, one of the largest subsidences and landslips ever known in Cheshire occurred. I pointed out that whenever fresh water reaches the rock salt it dissolves it. In certain districts in the immediate neighbourhood of Northwich the ground is completely honeycombed with rock-salt mines that had been worked out and abandoned. Into many of these fresh water had penetrated, and had become by solution strong brine This brine has of late been extensively pumped up, and many of these extensive cavities had become nearly empty. The thin crust of rock salt forming the roof of these old mines had become gradually thinner, owing to its solution by water, and on Monday morning the roof of one pit gave way, and let the superincumbent earth down into the mine, rifting and opening the ground to the surface. The surface rift passed across the bed of a large brook, and the water of the brook ran through the crevice into the mines below. In a short time the water made a more extensive cavity, and as the brook was cut in two about 200 yards above its entrance into a large lake that was drained by the Weaver River, the water in the lower portion of the brook and of the lake, as well as of the Weaver, commenced to return and run down the enlarged cavity. For four or five hours this return stream increased in velocity, pouring down the crater-like hole. Notwithstanding the water of the brook and the return water, as well as a large body of water from another small lake entering this cavity, the water standing in the funnel-shaped hole gradually lowered The velocity of both portions of the brook increased, and such was the force of the water that the bottom of the brook for 100 yards was scooped out from 2 feet in depth to 10 feet, and the banks were washed away,

making the brook from 30 to 40 feet wide instead of 20 as at first.

The quantity of water thus rushing down for twelve hours from the commencement would be fully 600,000 tons. The water in one direction over a surface of 160 acres was lowered one foot in the space of three hours Shortly after this water commenced to rush below it made its way through a weak portion of a barrier wall into a rock salt mine that was being worked. This mine, extending over fifteen acres, and having a worked-out depth of eighteen feet, was completely filled and all the tools, materials, waggons, tramways, &c., entirely lost. It will be quite impossible ever to pump out the water Besides this mine, all the old abandoned mines were filled, and the brine, which stood at 100 yards from the surface on the Sunday, stood at 24 yards on Monday night. The water being fresh, great damage was expected by the solution of the salt. This soon occurred, for an old mine that fell in forty two years ago, and the cavity of which had been filled with water, gave way, and suddenly the whole land over a circle of about 500 feet in diameter sank, and a large portion of water escaped into neighbouring pits. The ground cracked and rifted and subsided, and a length of road of 160 yards was destroyed, as also pipes conveying brine to the salt works A large reservoir holding brine was split across and all the brine let out, the rending of the earth passed through two kilns of bricks, dropping one-half of the kilns at least 2 feet On the Monday afternoon a tall chimney 90 feet in height became affected, and in a few hours fell with a great crash. The air that had filled the cavities below was forced out by the inrush of water, and caused all the pits and brooks near to bubble and boil violently, whilst in some of the rifts where water occurred miniature mud geysers were formed, throwing up mud 10 or 12 feet high. These appearances extended over a district between two brooks for the space of 2000 feet On Wednesday night a large hole 30 yards in diameter and 30 yards deep fell in, and more subsidences are daily expected, as the fresh water will eat away the pillars supporting the roofs of the abandoned mines.

The cavity formed on Monday is full of water, and the brook now runs through it Some idea may be formed of it when I mention that it is crater like, and of about 200 feet in diameter On sounding it on Wednesday I found a depth of 78 feet of water in the centre, and various depths from 70 to 60, 50, and so on to about 12 feet at the margin On Sunday, on the spot which is now 78 feet, there was a sandbank with its surface above the water.

Serious injury has been done to one set of salt works, and five sets are stopped for want of brine, the pipes being broken and the road destroyed.

As the salt trade increases these enormous sinkings keep increasing, and become more alarming in their character.

The Geology of East-Central Africa and the Subterranean Forest in Bombay

IN Mr. J. Thomson's very interesting "Notes on the Geology of East-Central Africa" (NATURE, vol xxiii. p 104) he remarks that doubtless the immense development of volcanic rocks described by myself (and I may add by several previous explorers) in Abyssinia is of the same age as the volcanic rocks at the Cape of Good Hope, assigned to the Trias.

Mr. Thomson has, I think, overlooked the circumstance that whatever may be the age of the Cape volcanic rocks, the traps of Abyssinia cannot be older than Jurassic As I have shown (*Quart. Jour. Geol. Soc.*, 1869, pp. 403, &c., and "Geology and Zoology of Abyssinia," pp 184, &c.), there are in the Abyssinian highlands two groups of bedded dolerites and trachytes, the upper of which rests unconformably on the lower, while the latter overlies limestone with Jurassic (Middle Jurassic) fossils

I trust that Mr. Thomson will pardon my suggesting the possibility of the Tanganyika sandstones being river valley deposits, like the Gondwana series of India, rather than lacustrine. I may be mistaken, but the description appears to me to indicate beds coarser than those usually deposited in an extensive lake basin.

In the same number of NATURE, p. 105, is a brief notice of a "Subterranean Forest in India." As I understand the account given, the forest should perhaps rather be termed submarine than subterranean. My object in calling attention to this notice however is to point out that a previous description of the same formation was published in the *Records* of the Geological Survey of India for 1878, vol xi p 302 This account is by Mr. G E. Ormiston, Resident Engineer, and agrees in all essential particulars with the note in NATURE I appended a few remarks on the geological bearing of the discovery. The "forest" has clearly been depressed, whilst neighbouring tracts in Bombay island appear to have been elevated in comparatively recent times.

W. T BLANFORD

Dr. Siemens's Gas-Grate

HAVING endeavoured for some years past to heat my study by gas appliances, and having utterly failed in obtaining a comfortable temperature of 60°, as a last effort to accomplish my object I had fitted into an ordinary grate Dr. Siemens's arrangement of copper and iron, the construction of which was communicated to the public in the pages of NATURE, vol. xxiii p. 25 Before giving the results of the trial of Dr. Siemens's gas-grate I may mention in what way my former gas-stoves failed My first gas-fire consisted of gas and asbestos, but this gave out fumes which were quite intolerable, my second trial was with a gas-stove reflecting heat from a copper lining, this not only failed to warm the room, but was a cheerless and grim apology for a fire, and to obtain even a moderate degree of temperature a constant and expensive consumption of gas was necessary With Dr. Siemens's gas-grate all that is required to produce a good cheerful fire radiating heat to all parts of the room, and maintaining a temperature from 60° to 62°, is to turn on the gas full for about twenty minutes, and as soon as the lower stratum of coke becomes incandescent, the gas may be quite turned off, the fuel, whether coke or anthracite, continuing to burn for five or six hours without any further expenditure of either gas or fuel

If the fire is required for a longer time, or if at any time a more rapid combustion is wanted, it is only necessary to turn on the gas again for a few minutes and add more fuel. This is my experience of Dr. Siemens's gas-grate, and I consider it a great boon to householders who desire well-warmed rooms combined with economy After the lucid description of the gas-grate given by Dr Siemens in NATURE, it would be presumption in me to discuss the scientific explanation of its action, I shall only, in conclusion, venture to claim for it the following advantages which I believe it to possess over every other kind of gas stove yet invented —

1 It gives a clear, smokeless, cheerful fire

2 It is most economical, and very soon pays the cost of the construction.

3 Being absolutely smokeless, contributes nothing to that constituent of our London fogs which renders them injurious in so many ways.

This last advantage, if multiplied by every householder at an outlay of 25*s*., adopting a cheaper modification than the copper and iron gas grate, we should before very long observe a marked change for the better in our London atmosphere, and the darkness, dirt, and destruction of property with which we Londoners are annually afflicted, would be things of the past

December 13 R DOUGLAS HALE

Geological Climates

I HAVE just read Mr. A R Wallace's letter in NATURE, vol. xxiii p. 124, but as I have not yet seen his book, "Island Life," although my bookseller had promised it, I shall defer my reply in NATURE until I shall have made myself master of his ideas.

For the present I shall only say —1. That Mr Wallace's proposal would benefit the Polar regions but not Bournemouth. 2 Mr. Wallace omits all mention of the *return cold currents* which the admission of two new Gulf Streams into the Arctic regions would produce. These currents would seriously lower the temperature of China and Japan, and also of the Ural Mountains and east of Europe.

SAMUEL HAUGHTON

Trinity College, Dublin, December 10

SOME weeks since the Rev. Prof. Haughton took exception to a brief letter of mine, in which I suggested that as a bamboo flourishes in Cooper's Hill College garden, in a northern aspect winter after winter, it could be used effectually in an argument relating to geological climates The bamboo being found in torrid India now, that at Cooper's Hill, if found in a future period, would, according to some geologists, indicate that the valley of the Thames was tropical formerly. My letter was

written because the Rev. Professor had written a very long one, in which he applied this kind of bad reasoning in relation to a bit of a leafy part of a tree found at Bournemouth in an Eocene deposit The leaves of his bit resemble those of *Araucaria Cunninghami* squashed, nevertheless a thermometric virtue is given to the fossil because this Araucaria is native in districts in Eastern Australia

Self-satisfied with his recognition of the similarity of the leaves, the Rev Professor coolly assumes that he has made out his species, and therefore demands the name of mine, giving me a scolding before I could possibly let him have it.

It is curious that the Rev Professor should not have seen the point of my letter, and the only explanation is that he was so taken up with the incomparable value of his delicate "self-registering plant thermometer." I did not believe in his discovery, and my bamboo—never mind whence it came—was quite as good in the method of argument as his so called Araucaria No botanist would feel satisfied with the coneless evidence of the Rev Professor, and his genus is in doubt as well as his species. With regard to this, Lindley stated years since that *Araucaria Cunninghami* is a "supposed species" in relation to the Norfolk Island *C excelsa* So the "self-registering thermometer" has neither bulb nor stem, and the spirit or the mercury represents the Rev. Professor's genius He bids me plant the bamboo in the sunny south west Not so, it is the damp soil and the shade which have permitted the stems to grow up to 10 feet 6 inches. He tells me that the bamboo grows in China that fact I had heard of before, and it has been strikingly impressed on many generations of Celestials Last week, but too late for my purpose of immediate publication in NATURE, I learned that the bamboo is of the sub-genus *Arundinacea*, and the species is *falcata* Its natural habitat is in the temperate Himalayas, where frosts, fogs, and north-east winds, such as plague the Thames Valley, are unknown

Finally I believe that the so-called *A Cunninghami* has grown of late years in the south of England

December 9 P. MARTIN DUNCAN

Hailstorm in Dorsetshire

AT about 1 30 on the 25th of last November, with a strong wind from the south-west, this place was visited by a hailstorm which lasted about five minutes, accompanied by rain and violent gusts of wind, and by a single vivid flash of lightning which was followed with scarcely more than an appreciable interval by the thunder.

The character of the hailstones which fell on the occasion, and which I examined before they could have undergone any important change induced by the higher temperature of the surrounding air, may be worth noting, for though they were not of very unusual size, and in most respects scarcely departed from what may be regarded as the typical condition of hailstones, they exhibited some features not generally met with in so well-marked a form.

In their simplest condition their shape was that of a sphere, and in every such case they consisted of a spherical nucleus of

opaque white ice enveloped by a concentric shell of ice perfectly transparent and homogeneous, showing none of the radial striæ often met with in hailstones (Fig. 1) The largest measured about half an inch in diameter, the nucleus having a diameter of about a quarter of an inch. The appearance of the opaque white nucleus surrounded by its thick crystal-clear envelope was very striking and beautiful.

In many cases two such hailstones were united firmly to one another, doubtless by a process of regelation after contact. In some of these the transparent envelope was continuous around each of the nuclei in the plane of contact (Fig 2) In others it was here deficient, and the two nuclei were then in immediate contact with one another (Fig. 3). The difference thus presented is not without significance as affording evidence that there are two distinct conditions under which the union of hailstones by regelation may occur; for it is probable that in the former case the contact and regelation had taken place directly between the nuclei while as yet free from the investing shell of clear ice which had afterwards formed around the twin nuclei, while in the latter case the envelope had already existed before the contact and regelation of the hailstones.

Another frequent occurrence was the presence of one or two little piriform offsets, which projected from the surface of the hailstone, and were, like the envelope itself, formed of clear homogeneous ice (Fig. 4) In a paper published in the *Proc.* Asiatic Society for June, 1880, to which my attention has been called by Mr. Scott of the Meteorological Office, very similar club-shaped projections of transparent ice are described by Mr. Blanford in large hailstones figured by Col. Godwin-Austen as having fallen at Calcutta in March, 1877

It is possible that in these cases the projections had originally the form of crystals, and that their faces and angles had been rounded off in passing through a warmer region of the atmosphere, such radiating crystals of ice not being unknown In a memoir by Abich ("Ueber Kugel Hagel im Unterem Kaukasus," Vienna, 1879), for a knowledge of which I am also indebted to Mr Scott, an account is given of certain very large hailstones which fell at Tiflis in Georgia, and had large ice crystals radiating from the surface. GEO. J ALLMAN

Ardmore, Parkstone, Dorset, December 11

Sargassum

I FIND in NATURE, vol xxiii p. 70, a short report on my paper, "Revision von Sargassum," with several objections, which I believe to be erroneous It is said that the fragments occurring sometimes on the open sea, the so called *Sargassum bacciferum*, should have a bright yellow colour Not long ago I received fresh samples thereof from the Sargasso Sea, which are not yellow at all, these fragments are never bright yellow, but of the same brown, varying to yellowish colour as decaying *Fucus vesiculosus* I observed the latter, for instance, in this condition in several fjords of Norway, where I found broken Fucus in greater quantities than ever I did Sargassum in the open sea between England and the West Indies

Macrocystis pyrifera shows always stem and leaves entangled in a ball, if broken and swimming in the open sea (*vide* p. 235 of my treatise), and the Sargasso fragments of the open sea are also often entangled in compact balls, as Sir Wyville Thomson states ("The Atlantic," i. 194), and as it may be seen on my phototypic table, Fig. 1

If the floating Sargassum should have no reproductive organs, this would be no difficulty, but rather a confirmation of my views on the fragmentary nature of swimming Sargassum, for a particular pelagic species could not be without reproductive organs Besides there have been found "with certainty" sometimes samples in the open sea with reproductive organs, and I gave an explanation of their seldom occurrence by want or breaking off of the air vesicles The writer on my paper is mistaken in comparing Macrocystis and Fucus with Sargassum, for the air-vesicles and reproductive organs of Sargassum are separate from the leaves and isolated on thin stalks, which break off easily, while those of Fucus and Macrocystis are never separate, but in the middle of the leaf or on the base, or on the broad end of the leaf or thallus. Therefore swimming Sargassum is found often without reproductive organs, and its air-vesicles are often broken off, whilst on Macrocystis and Fucus such a separation is not possible. Having refuted those objections, and having also brought in my paper many more arguments against the existence and vegetation of *Sargassum bacciferum* than there are mentioned in the short report, I hope that my results on Sargassum will now generally be accepted

Leipzig-Eutritzsch, December 4 OTTO KUNTZE

Note on an Acoustical Constant

THE number of vibrations executed in a second by a stretched string is generally represented in the text books by a formula expressing the method of its variation with the determining circumstances, such as—

$$n \propto \frac{1}{dl}\sqrt{\frac{T}{s}},$$

where d is the diameter, l the length, s the specific gravity of the string, and T the tension or stretching force, but the absolute number of vibrations is not generally given by the formula.

Now if we write instead of the above—

$$n = \frac{k}{d\,l}\sqrt{\frac{T}{s}},$$

where k is some constant, it is evident that k will not depend on the nature of the string but solely on the system of units employed to express d, l, and T.

If C.G S. units be employed, we have, as stated in Prof. Everett's translation of Deschanel—

$$n = \frac{1}{2\,l}\sqrt{\frac{T}{m}},^{1}$$

where m is the mass of unit length; and as we may write instead of m, $\pi r^2 s$, r being the radius of the wire, we shall have—

$$n = \frac{1}{\sqrt{\pi}} \cdot \frac{1}{2\,r\,l} \cdot \sqrt{\frac{T}{s}}, \text{ or } \frac{1}{\sqrt{\pi}} \cdot \frac{1}{d\,l} \cdot \sqrt{\frac{T}{s}},$$

so that here $k = \frac{1}{\sqrt{\pi}} = \cdot5642$ approximately.

With any other system of units we may of course determine k from the value just given, by multiplying or dividing by the ratios of the new to the C G.S. units, for example, if d be expressed in millimetres, l in metres, and T in kilogrammes, our new constant would be—

$$k = \frac{1}{\sqrt{\pi}} \cdot \frac{10}{1} \cdot \frac{1}{100} \sqrt{981000}$$

$$= \frac{99\cdot04}{\sqrt{\pi}} = 55\cdot87.$$

But we may also determine k directly for any system of units in the following manner:—If, in the formula—

$$n = \frac{k}{d\,l}\sqrt{\frac{T}{s}},$$

we make d, l, T, s, each unity, we shall have—

$$n = k$$

Imagine then a wire of water, 1 mm. diam., 1 metre long, stretched by a weight of 1 kilo., its weight would be 7854 grm., and H, the "tension length," or length which would be equal in weight to the stretching weight, would be $\frac{1000}{\cdot7854}$ $= 1273\cdot2$ metres. The velocity v of transmission of a pulse along the wire would be $\sqrt{g\,H} = \sqrt{9\cdot81 \times 1273\cdot2} = 111\cdot76$ metres per second, and the number of vibrations per second—

$$n = \frac{v}{2\,l} = \frac{111\cdot76}{2} = 55\cdot88 = k,$$

the same figure as that obtained above.

If the units in which d, l, and T are expressed are respectively the tenth of an inch, the foot, and the pound, k becomes 48·66

In the later editions of Ganot's "Physics" we find the formula—

$$n = 9\cdot8257\sqrt{\frac{c}{l}}$$

given, where c is the "tension length," and l the length of the string, both expressed in inches. This formula would of course be of more easy application than those given above when we know the weight per foot of the string, but does not directly show the relation of n to the diameter and specific gravity

Meteors

ON the evening of November 20 at about 8 p m my attention was attracted by a number of meteors appearing as often as once per minute in different quarters of the heavens, but pursuing courses apparently radiating from a point near the constellation Andromeda

M A. VEEDER

Lyons, New York, November 22

THE PROBABILITY OF PHYLLOXERA CROSSING THE TROPICS

MUCH alarm has been felt by the wine-growers of South Africa at the possibility of the phylloxera being introduced into the Cape vineyards Very stringent regulations have been framed in consequence, prohibiting the importation of living plants or vegetables in any form, and so rigidly have these regulations been carried out that it is stated that, in accordance with them, a cargo of potatoes from New Zealand was destroyed on its reaching Capetown

It is generally conceded by the experts who have been consulted that the importation of vines, on the tissues of which the phylloxera would be able to live in transit, must be prohibited The phylloxera can however, it is admitted, feed on no other plant but the vine, and the important question for the South African Government to decide is whether it is really needful to exclude other plants or vegetables besides the vine In order to obtain the best opinion upon this point, Dr Maxime Cornu was consulted He accordingly drew up several reports, in which he expresses the opinion that, though extremely unlikely, it is still theoretically possible that the phylloxera should be conveyed from Europe to South Africa by means of other vegetable products than the vine, and he therefore supports the prohibitive action taken by the Cape Government

The inconvenience to the community which such a policy involves is necessarily considerable The grounds of Dr Maxime Cornu's decision have therefore been carefully considered by an entomologist who has studied the subject and who has drawn up the following notes The question is of great importance to all wine-growing countries in the southern hemisphere, and as these doubtless contain many readers of NATURE, I think the publication of these notes in its columns will give them the best opportunity of being fairly considered

W. T T. D.

Notes on Dr Cornu's Reports on the Phylloxera, and on the Protective Measures against its Introduction

Among the "truths" laid down in the first report, No. I is, "The *Phylloxera vastatrix* lives only upon the vine" This is emphasised in the third report ("Memorandum on Laws of Protection, &c"), Paragraph No IV, stating, "they (the insects) can, moreover, subsist only upon the vine"

Notwithstanding these unreserved statements of this fundamental fact in the life history of phylloxera, the same "Memorandum on Laws of Protection, &c," proceeds (in its "General Conclusion") to recommend, "if such a course were possible," the imitation of "the example set by Algeria, and to forbid the introduction of all vegetable products whatever, with the exception of those which are absolutely required for consumption"

It may well be asked on what ground such a recommendation is based After stating (Third Report, Paragraph IV) that the phylloxera cannot live when dissociated from the vine for more than four or five days, and requires protection from dessication in any case, Dr

Cornu proceeds (Paragraph V) to sketch "the most favourable conditions for the introduction of the insect" as follows:—"A phylloxera is removed in the soil, say a pregnant mother, which survives for a period of five days; it lays an egg before dying, the egg takes fifteen days to hatch (at the mean temperature of 59 deg Fahr), and the young insect which is produced five days to die. This makes in all twenty-five days" That is to say, that the maternal phylloxera, when in *articulo mortis* at the end of her five days' dessication and starvation, is to lay an egg; that this egg, produced under such extraordinary conditions, is to hatch in due course, and, after undergoing total starvation from its birth, is to live out the normal term of five days allotted to the mother (presumably well fed until she started on the dolorous voyage), and after all this is to land at the Cape and propagate its species in the nearest vineyard at hand! If these are "the most favourable conditions" under which the phylloxera would be introduced, we may surely say with Dr. Cornu in another part of the same report (Paragraph VII. *a*) that "it would require a concatenation of circumstances which it is difficult to imagine to bring about the misfortune of the insect's introduction." It is as well also to note that the writer expressly states (Paragraph V.) that the egg's hatching is accelerated when the temperature exceeds 59 deg Fahr., so that in the supposed case, if the starveling progeny ever did see the light on the voyage, it would probably emerge in a tropical temperature long before the normal fifteen days allowed, and so resign its life of total abstinence before reaching the promised land of plenty at the Cape.

Let us now turn to the "winter egg," which, as Dr Cornu states (Paragraph VI.), "is particularly to be dreaded" This is the rarest condition of the insect, each female of the generation which includes both sexes laying only one egg (Paragraph VI)

"It is to this egg alone that the introduction of the phylloxera in packing-cases, straw, &c, could be attributed, this would however require confirmation; in fact I am not aware of any well-authenticated instance of the introduction of the phylloxera resulting from the transmission of the winter egg" (Paragraph VII).

This admission on the writer's part seems to reduce any apprehension about the winter egg to infinitesimal proportions, especially when it is noted that the "winter egg," as its title implies, is a state limited to cold weather, and "commences to develop at the return of the fine weather" (Paragraph VI.) If a specimen of this rare *œuf d'hiver* did by any chance (in the absence of the vine-stems or branches upon which it is laid) start on a voyage for South Africa, we may be very sure that in its passage through the whole extent of both tropics it would very speedily cease to merit its title, and become a miserable *phylloxèra d'été*, only to share the fate of its luckless relative, produced from the last dying egg of the *mère pondeuse*. It does not mend matters to find Dr. Cornu stating in italics (Paragraph VII.), "Such introduction is nevertheless possible from a scientific point of view" Impossibility can with accuracy be predicated of but very few propositions, as a rule it is safer to say of most matters apparently incredible that it is next to impossible, and this may very certainly be said in the present case, and when all known facts and conditions place every probability against a bare possibility, wise men will know how to act.

As long as vines and all parts of vines from abroad are kept out of the Cape, the requirements of the wine industry are fully met This prohibition was put in force by the late Government, by Proclamation No 88, of November 30, 1876, and has been in force ever since that date. As late as the 4th December last, attention was specially directed to this Proclamation, with the intimation that its provisions would be strictly enforced (in Government Notice, No. 1288, of 1879) The present superfluous and vexatious restrictions were added by Proclamation No 14, of January, 1880, and all the facts adduced by Dr. Cornu point to their futility.

SONGS OF THE SCIENCES—I. ZOOLOGY

WE must regard it as a noteworthy sign that science has begun to percolate so through society generally that it has reached the pages of *Punch* Almost every week we find a bit of more or less telling waggery, and last week the first of a series of "Songs of the Sciences" appeared, which we reproduce:—

Oh! merry is the Madrepore that sits beside the sea,
The cheery little Coralline hath many charms for me;
I love the fine Echinoderms of azure, green, and grey,
That handled roughly fling their arms impulsively away:
Then bring me here the microscope and let me see the cells,
Wherein the little Zoophite like garden floweret dwells.

We'll take the fair Anemone from off its rocky seat,
Since Rondeletius has said when fried 'tis good to eat;
Dyspeptics from Sea-Cucumbers a lesson well may win,
They blithely take their organs out and then put fresh ones in.
The Rotifer in whirling round may surely bear the bell,
With Oceanic Hydrozoids that Huxley knows so well.

You've heard of the Octopus, 'tis a pleasant thing to know,
He has a ganglion makes him blush not red, but white as snow:
And why the strange Cercaria, to go a long way back,
Wears ever, as some ladies do, a fashionable "sac";
And how the Prawn has parasites that on his head make holes,
Ask Dr. Cobbold and he'll say they're just like tiny soles

Then study well zoology, and add unto your store,
The tales of Biogenesis and Protoplasmic lore.
As Paley neatly has observed, when into life they burst,
The frog and the philosopher are just the same at first.
But what's the origin of life remains a puzzle still,
Let Tyndall, Haeckel, Bastian go wrangle as they will.

THE AUGUST AURORAS

AS I had the pleasure of witnessing to great advantage at Christiania the superb aurora of August 12 last, as well as that of the 13th, it is possible that some account of these displays as seen in Norway may be useful for comparison with accounts of their appearance in England.

My attention was first drawn to the aurora on going into the open air at 11 p m At 10.30 p.m a friend had remarked that the night seemed unusually dark, and that the stars were shining brightly. When first seen by me the aurora consisted of a wide arch of diffused light, the centre of which was about 30° in height. A few broad streamers were then beginning to appear. I walked as quickly as possible to a hill whence a good view could be obtained, but I had hardly got there before the aurora had already reached, about 11.10 p m, its maximum splendour. Broad streamers had by this time covered almost the whole of the northern half of the heavens, converging to a point considerably south of the zenith, forming a grand corona The arch was still highly luminous, and from its upper margin coruscations or waves of white light shot up every two or three seconds towards the zenith. At this time also there suddenly appeared to the east of magnetic north a splendid sheaf of rays proceeding from the horizon altogether beyond the auroral arch, and apparently in complete independence of it. These rays, through bright, attained an elevation of only some 35°, and belonged apparently to a distinct auroral discharge. At 11.15 the arch had already begun to fade, but a mass of rays shone out brightly near its eastern termination. Throughout the display I was struck by the tendency to the formation of compact bodies of streamers which seemed to flank each end of the arch. As the arch faded the pulsations of

light increased in frequency and brilliancy, and at 11.25 they might be described as broad flashes overspreading a large part of the northern half of the sky, always travelling upwards, and sometimes passing the zenith. The main body of streamers had by this time mostly faded, after going through an extraordinary series of changes which I found it quite impossible to record Every minute or two new rays would strike up to the zenith, or sometimes beyond, and every now and then a portion of an older ray would suddenly shine out with a kind of phosphoric light.

The display now rapidly faded, and though at 11 35 and again about 11.45 there were minor reappearances of rays, the aurora seemed to be near its end, and I returned home.

The brightness of the phenomenon was somewhat delusive, for when a superb corona of rays covered the northern sky, I could only just read my watch by its light, and could not read what I endeavoured to write down on paper The light was either white or of a greenish yellow tinge. There was no trace of the redness or other colours seen on other occasions.

By very good fortune I was able to watch the aurora of the next night (August 13) under the most favourable possible circumstances, namely, while steaming down the Christiania Fyord, in the steamship *Angelo*, during a beautiful calm evening. The aurora began at 10 20 p.m with a very faint uniform arch, or rather line of white light, appearing 8° or 10° above the horizon, with difficulty distinguished from the twilight. This soon faded away entirely, but at 10 35 reappeared as a very distinct luminous arch, separated by a dark space from the twilight. Some slight signs of rays now also appeared

At 10.45 the arch seemed to be rising somewhat, without ever attaining a height of more than about 15°. The lower edge became indented by ray-like notches There was a tendency to the formation of streamers at the flanks. At 10 50 a fine single ray shot up from the horizon right through the arch, at 10° to west of true north. Streamers also began to appear above the arch, and especially at its eastern end, but the streamers were in no way comparable to those of the previous night The arch now began to lose its previous regular form, and to go through a remarkable series of gradual changes and contortions, which it is impossible to describe By degrees the eastern end became incurved in the manner of a folded curtain (like the pictures of auroras in the Polar regions which we see in books), and a few fragments of rays tended to form an inferior arch.

For more than an hour the light of this aurora was steady; but about 11 30 p m pulsations first began to appear faintly, soon increasing in frequency and width. As the pulsations grew the arch almost insensibly disappeared, but patches of light and fragments of rays occupied the sky above where the arch had been, and were every instant lighted up, as it were, by the passing coruscations These flashes of light became more and more frequent, following each other every second, or even several times in a second, so as to produce at last a kind of rustling or dancing appearance. They were most intense upon the rays and patches, but were not confined to them. At 12.30 the display was failing, the waves being less frequent. At 1 a.m. there remained only a few irregular patches of faint, steady light, with occasional flashing waves. The light was again white, or greenish yellow. On neither occasion did the aurora seem to have the slightest relation to the ordinary vaporous clouds of the atmosphere, nor did the dark space beneath the arch seem to be more than might be explained as the effect of contrast.

Mr. Thomas Bennett, who is well known to all Norwegian travellers, and has resided many years in Christiania, informed me that the aurora of the 12th was probably the finest he had ever seen among the many grand displays which occur in Norway. Though I have witnessed several fine auroras, including some of those seen in the United States in August and September, 1859, and two fine displays of the Aurora Australis (September 14 and 16, 1854), I cannot call to mind that I ever saw coruscations or waves of electric light at all approaching those seen at Christiania on this occasion. The books say comparatively little about these coruscations, nor do the letters in NATURE, vol. xxii. p 361, mention them as seen in England Yet they probably represent the most important part of the phenomenon, the active discharge of electric energy

I neither saw nor heard anything in Norway of an aurora on the night of August 11. About the dates I give there can be no possible mistake, because the steamboat from Christiania to Hull departed as usual on Friday evening (August 13) The times mentioned are the local times by the public clock at the Christiania University Buildings. W. STANLEY JEVONS

P.S.—The above account was mostly written a few days after my return to London, according to notes taken at the time. I print it now for what it may be worth. After thinking the matter over for three months, and comparing the auroral coruscations above described with the exquisite discoveries of Mr. Crookes, taking into account also some remarks in the article on auroras in the new edition of the "Encyclopædia Britannica," I venture to make the suggestion that these coruscations arise from highly tenuous matter (in what Mr. Crookes calls the *radiant state*) projected through the higher parts of the atmosphere. It is not possible by words to give an impression of such a phenomenon in the least degree approaching to that naturally acquired by watching it under favourable circumstances for several hours. My belief is, that during the auroras described, *puffs*, as it were, of radiant matter were discharged at a great elevation above the earth's surface, and the luminosity of these puffs perhaps arises from conflicts between the projected molecules and those already spread about the almost vacuous space. The arch and most of the streamers probably belong to a lower, though still a very high part of the earth's atmosphere, but certain of the streamers, as well as patches of luminous matter seen on the night of the 13th, certainly exist in the lofty regions through which the radiant matter is projected The explanation of the streamers must probably be approached through that of the coruscations, but they are effects of a very different kind W. November 22

THE INFLUENCE OF A TUNING-FORK ON THE GARDEN SPIDER

HAVING made some observations on the garden spider which are I believe new, I send a short account of them in the hope that they may be of interest to the readers of NATURE

Last autumn, while watching some spiders spinning their beautiful geometrical webs, it occurred to me to try what effect a tuning-fork would have upon them. On sounding an A fork and lightly touching with it any leaf or other support of the web or any portion of the web itself, I found that the spider, if at the centre of the web, rapidly slews round so as to face the direction of the fork, feeling with its fore feet along which radial thread the vibration travels. Having become satisfied on this point, it next darts along that thread till it reaches either the fork itself or a junction of two or more threads, the right one of which it instantly determines as before. If the fork is not removed when the spider has arrived it seems to have the same charm as any fly. for the spider seizes it, embraces it, and runs about on the legs of the fork as often as it is made to sound, never seeming to learn

by experience that other things may buzz besides its natural food.

If the spider is not at the centre of the web at the time that the fork is applied, it cannot tell which way to go until it has been to the centre to ascertain which radial thread is vibrating, unless of course it should happen to be on that particular thread or on a stretched supporting thread in contact with the fork

If when a spider has been enticed to the edge of the web the fork is withdrawn and then gradually brought near, the spider is aware of its presence and of its direction, and reaches out as far as possible in the direction of the fork, but if a sounding fork is gradually brought near a spider that has not been disturbed, but which is waiting as usual in the middle of the web, then instead of reaching out towards the fork the spider instantly drops—at the end of a thread of course If under these conditions the fork is made to touch any part of the web, the spider is aware of the fact and climbs the thread and reaches the fork with marvellous rapidity. The spider never leaves the centre of the web without a thread along which to travel back If after enticing a spider out we cut this thread with a pair of scissors, the spider seems to be unable to get back without doing considerable damage to the web, generally gumming together the sticky parallel threads in groups of three and four.

By means of a tuning-fork a spider may be made to eat what it would otherwise avoid I took a fly that had been drowned in paraffin and put it into a spider's web and then attracted the spider by touching the fly with a fork. When the spider had come to the conclusion that it was not suitable food and was leaving it, I touched the fly again This had the same effect as before, and as often as the spider began to leave the fly I again touched it, and by this means compelled the spider to eat a large portion of the fly.

The few house-spiders that I have found do not seem to appreciate the tuning-fork, but retreat into their hiding-places as when frightened, yet the supposed fondness of spiders for music must surely have some connection with these observations, and when they come out to listen is it not that they cannot tell which way to proceed?

The few observations that I have made are necessarily imperfect, but I send them, as they afford a method which might lead a naturalist to notice habits otherwise difficult to observe, and so to arrive at conclusions which I in my ignorance of natural history must leave to others.

C. V. BOYS

Physical Laboratory, South Kensington

THE MINERALOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND

THERE was a time, now almost beyond the memory even of the oldest inhabitant, when the stillness of our learned halls was unbroken by the wrangle of contending geologists, when the science of geology could not be said yet to exist, when those who occupied themselves with stones found a congenial atmosphere of solemnity in the quiet domain of crystallography, whence with the boldness of adventurers they made little excursions into the more open and dangerous waters of chemistry. Days of slumberous peace as they now seem to one who turns over the ponderous dusty pages in which their records are duly chronicled! To the mineralogist of those days the interest and importance of rock-masses was measured by their richness or poorness in mineral specimens. Surrounded by his cases of minerals—the reward of years of patient toil and judicious expenditure, with what tender interest would he survey his treasures! We knew him in old times, yea and loved him. Enthusiastically would he describe how he had contrived to secure that priceless unique crystal; how day after day he had searched the rocks in vain, till at last one lucky stroke of the hammer laid open that magnificent druse; how he had bought that matchless group from a sailor who used it to keep down the lid of his tobacco box. Kindly too he was, and all the more if you took interest in his favourite pursuit. Ask him to tell you the difference between two resembling minerals, and he would launch out with evident relish into his "external characters." Lovingly would he handle the specimens, as if they were the children of his old age. Eagerly would he descant upon the difference between "lamellar distinct concretions"; how some were "indeterminate curved lamellar," others were "fortifications-wise bent." And then would follow the whole string of characters—"semi-hard," "not particularly difficultly frangible," "supernatant," "pretty cold," "not particularly heavy," between "aurora-red" and "hyacinth-red," or between "mountain-green" and "celandine-green." Such jargon it seemed to youthful ears! One could not but admire indeed its methodical precision, but the questions ever forced themselves on one's mind—What is the living truth underlying it all? Were minerals really created merely as a basis for our old friend's systems of classification? Or can they not be made to yield up some intelligible record of their own history and of the planet of which they form a part?

When the discoveries of William Smith drew off the attention of students to the marvels revealed by stratigraphical geology, mineralogy rapidly sank into neglect in this country. By a curious revulsion of opinion rocks were now appraised as of importance in proportion as mere mineral specimens were absent from them, for where these occurred organic remains were usually not to be looked for; and organic remains now took the place of minerals. Men who would formerly have trudged cheerfully a whole day with a 14-lb. hammer on their shoulders to secure a few minerals were now to be seen as enthusiastically hunting for ammonites, gryphaeas, belemnites, echini, fossil fishes, and other buried treasures of the stratified formations. Unmeasured was the scorn of the veteran mineralogist for this new-fangled pursuit. To neglect such attractive objects as minerals, with their exquisite forms and colours, for the dingy and fragmentary relics of extinct whelks, lobsters, and other pre-adamite vermin seemed to him an utterly unaccountable form of madness. And so his beloved cabinet became dearer to him than ever. In its quiet retreat he lived with his specimens in the past, and allowed the strong rising tide of palæontology to rush and roar past him unheeded.

But cycles appear in scientific as in political opinion For some years past there has been a growing conviction that palæontology has had a long enough monopoly of power in the geological commonwealth, and that the mineralogical side of the science has in this country been unduly neglected and discouraged. The attention now bestowed among us upon petrographical research is a pleasing proof of the reality and steady progress of this reaction Another token of the same change is supplied by the foundation and encouraging growth of the Mineralogical Society of Great Britain and Ireland This society was instituted in the early part of the year 1876. It counts among its members a large and increasing number of the best geologists in the three kingdoms. But its operations are carried on so quietly and unostentatiously that its work and aims are probably not yet so widely known as they deserve to be. A body gathered under the leadership of Sorby and Heddle is one which may count on support from all to whom the advancement of mineralogy and mineralogical geology among us is an object of interest. As a rule our scientific societies are bodies with a local habitation, gathering most of their effective members from the district in which their rooms are placed. But the Mineralogical Society, as its name denotes, embraces the whole United Kingdom. It has no buildings of its own nor any one special home. Its meetings, like those of the British Association on a large scale, are

held from time to time in different towns throughout the country, its object being to form a bond of union among those who cultivate mineralogy or who wish to see this science restored to the place which it ought to hold in a land where so much sound geological work is being done The Society publishes a "Mineralogical Magazine," of which three volumes and part of a fourth have already appeared. This publication contains numerous papers by Dr Heddle and the indefatigable secretary, Mr Collins, also some by Mr Sorby, the late Mr J C Ward, Prof. Bonney, and other well-known writers No one need fear to encounter in its pages the resuscitated ghosts of the old mineralogical "Dryasdusts" Peace to their manes! They did good though limited work in their day, which deserves our respect for its thoroughness. But, with affectionate reverence for these early masters and their crabbed lingo, we breathe a more open breezy atmosphere now. The mineralogist's ken sweeps far beyond the limits of his cabinet and laboratory. Hand-in-hand with the geologist and palæontologist, being elder brother to both, he takes his share in the task of unravelling the structure and history of the earth. Towards the attainment of this union the Mineralogical Society aims, and it deserves the heartiest wishes for its success

ARCH. GEIKIE

SMOKELESS LONDON

I WRITE for the purpose of expounding a scheme which, if adopted, would make London a smokeless city

When taking upon myself to explain a subject in a few minutes which has taken many years to develop in my own mind, there is a great temptation to put the reader in possession of the steps which led to the conclusion The conclusion itself however has so much to recommend it that I will confine myself to the results of my reasoning only. It is enough to say that they were arrived at to a great extent by an exhaustive exclusion of less feasible plans

First then I propose to take advantage of the existing plant of the gas companies I find they are amply sufficient for the purpose

Instead of taking 10,000 cubic feet of gas per ton from the coal, I propose to take 3333 cubic feet, and to pass three times the quantity through the retorts, or any other proportion that may be found most convenient. The result of doing so is startling

The companies will have double the quantity of by-products they have at present in the shape of tar and ammoniacal liquids, the community will have 24-candle gas instead of 16-candle gas; the fuel resulting from the process will light readily, and it will make a cheerful fire that gives out 20 per cent more heat than common coal, London would become a smokeless city

In dealing with the figures I shall take them roughly, but in such a way that by including a few outlying corporations they could be made absolutely correct.

I take the total annual consumption of coal in London to be 6,000,000 tons Of this I take 2,000,000 tons to be the annual consumption of the gas companies The total quantity of fuel used for general purposes I take to be 4,000,000 tons of coal and 1,000,000 tons of coke sold by the gas companies.

We shall now see what would be the result if we treat the whole of the 6,000,000 tons in the retorts on an extraction of less than three hours, instead of the six hours at present prevailing.

The total quantity of 16-candle gas consumed in London may be taken at 20,000,000,000 cubic feet. This would be at the rate of 3333 cubic feet per ton upon 6,000,000 tons, the total quantity of coal consumed in London. The residual smokeless fuel would amount to 5,100,000 tons. Of this 1,000,000 tons would be required for the extraction of the gas, leaving 4,100,000 available for the general uses of the community This has to be compared with the 4,000,000 tons of coal and the 1,000,000 tons of coke already referred to as consumed at present Now the smokeless fuel which results from an extraction of 3333 cubic feet of gas per ton has a heating capacity fully 20 per cent greater than common coal, and 10 per cent. greater than coke. This gives us the exact equivalents of the 5,000,000 tons of fuel at present in use

So far the account as regards the fuel available for the community balances. We may now deal with the difference in value between 16 and 24-candle gas As the value of the gas varies directly as its illuminating power, the calculation is very simple If we take the average price of 16-candle-gas to be 3*s*. 6*d* per thousand cubic feet we shall find the total value of the 20,000,000,000 consumed in London to be 3,500,000*l*, but as we have by my scheme the same quantity of 24-candle-gas, the value will be increased to 5,250,000*l*; here then we have an annual sum of 1,750,000*l* to place to the credit of the system.

Turning now to the by-products seeing the gas companies by the new arrangements would subject three times the quantity of coal to the heat of their retorts during the period when the tar and ammoniacal liquors pass off most rapidly, I do not think I am wrong in estimating the yield at double its present amount Taking this upon the tar and ammonia to yield 3*s*. 9*d* per ton of coal, we find the total value of these by products to be, at present, on the supposed consumption by the gas companies of 2,000,000 tons of coal per annum, 375,000*l* This being doubled under my scheme, an additional sum of 375,000*l* must be placed to its credit.

But the basis upon which we have hitherto been arguing is that the gas companies under the proposed scheme are getting their coal for nothing. We have been supposing that the community become the purchasers of 6,000,000 tons of coal and hand it to the gas companies At present London only pays for its general consumption on 4,000,000 tons of coal and 1,000,000 tons of coke. Let us now suppose that the companies pay the same sum annually that they do at present for their coals; if so, they would pay upon 2,000,000 tons, or an annual amount of 1,600,000*l*, if their coals cost 16*s*. per ton From this falls to be deducted the money they at present draw from their sales of coke, which, when taken at 6*s* per ton of coal carbonised under the existing system, still leaves a sum of 1,000,000*l*, which they could afford to pay per annum for the use of the 6,000,000 tons of fuel as proposed in my scheme. We will now take the total payments of the community for their coal to be upon 6,000,000 tons, for which we will further suppose they pay at the rate of 16*s* per ton first cost This would amount to 4,800,000*l* per annum From this falls to be deducted the 1,000,000*l* contributed by the gas companies for the use of the fuel, also the 1,750,000*l* charged on the difference between the 16- and 24 candle gas already referred to, also the sum of 375,000*l* of additional income from the by-products This would leave a net sum paid by the community for its fuel under my scheme of 1,675,000*l* Under the present system they have to pay, say 16*s*. per ton on 4,000,000 tons of coal, and say 12*s* per ton on 1,000,000 tons of coke This makes in all the sum of 3,800,000 per annum Here then we have a balance in favour of my scheme of 2,125,000*l* annually This may be taken as the yearly value of London smoke, which I propose to convert into useful products by *the plant at present in use*.

I have only in conclusion to say one or two words about the efficiency of the scheme as regards the fuel It lights easily, it gives off no smoke, it makes a cheerful fire, it gives out more heat than either coal or coke, it will be cheaper per heat-unit than the coal at present in use, London would become a smokeless city, and all that would fall to be deducted from the sum of 2,125,000*l*. per annum would be confined to a few items, such as the cost

of additional workmen employed in charging the retorts, interest upon additional capital required for transit appliances, and the terms to be made with the gas companies for carrying out the scheme [1]

I cannot close without acknowledging the help I have received from Mr. Wallace, the gas manager at Woolwich Arsenal, and the valuable information obtained from Mr Field's tabulated accounts of the London gas companies. So far as I am aware my contributions to the *Builder* and elsewhere are the only writing on the subject of my scheme that has ever been made public.

W. D. SCOTT MONCRIEFF

Westminster, December 13

NEW GUINEA [2]

OF the few travellers who have attempted to explore the great island of New Guinea, Signor D'Albertis must undoubtedly be considered the chief, since he alone has made extensive and repeated journeys both in the north-western and the south-eastern parts of the island, and has thus been able to examine and compare some of the most distinct tribes or races which inhabit the country. The narrative of his travels has therefore been looked for with some interest, for though several of his journeys have been more or less fully described in newspapers and magazines, it was felt that much must remain to be told, and that so energetic a traveller would probably be able to throw some fuller light on the hitherto doubtful affinities and relations of the Papuan races

Leaving Genoa in November, 1871, in company with the well-known traveller and botanist Dr. Beccari, and making short excursions in Java and the Moluccas, our travellers hired a small schooner at Amboyna in March, 1872, to take them to Outanata, on the south coast of New Guinea, and after some delays at Goram seeking a pilot and interpreter, on April 9 D'Albertis records in his journal. "A memorable day! At last I tread the mys-

FIG 1—Mount Yule Range, seen from Yule Island

terious land. At last, leaping on shore this morning, I exclaimed, 'We are in New Guinea!'"

Finding no safe or convenient place to stay at on the south coast, they proceeded to Salwati and fixed their abode for some time at Sorong, a small island close to the north-western extremity of the main land of Papua From this point they made excursions into the interior, and D'Albertis resided some time at the inland village of Ramoi, where he was near dying of dropsy and fever. They then went in a native vessel to Dorey Harbour, where they arrived in August, and sttled themselves at Andai Village, where a German missionary resides. Here they had a house built, which was their headquarters till November, and D'Albertis succeeded in spending some weeks at Hatam, a village on Mount Arfak, about 3500 feet above the sea, and in the midst of the forests inhabited by the finest and rarest of the birds of paradise. On the very day after his arrival here he shot both the shielded and the six-shafted paradise-birds (*Lophorina atra* and *Parotia sexpennis*), two species which had certainly never before been seen alive or freshly killed by any European; and before he left this spot he obtained many other rare species, besides an altogether new and beautiful kind, which has been named *Drepanornis albertisii*

Constant attacks of fever and dropsy, however, reduced him to such a state of weakness that it was absolutely necessary to seek a change of climate, and returning to

[1] By experiment I find that the greater heating power of the fuel in excess of the coke more than makes up for the cooling which takes place on account of the more frequent charging of the retorts

[2] "New Guinea What I Did and What I Saw" By L M D'Albertis, Officer of the Order of the Crown of Italy, &c., &c In two volumes (London. Sampson Low, Marston, Searle and Rivington, 1880)

Amboyna he was taken by an Italian man-of-war to Sydney, making some stay at the Aru Islands and South-Eastern New Guinea on the way. Thence he went home by way of the Sandwich Islands, San Francisco, and New York, reaching Europe in April, 1874, and thus terminating his first voyage to the far east.

When leaving Dorey in the end of 1872 he had determined to return to the north coast and to penetrate further into its forest-clad mountains, but the subsequent journeys of Dr Mayer, of which he heard at Sydney, and Dr Beccari's intention to return to the same district, induced him to turn his attention to the south, where he had obtained from the natives the skin of a new bird of paradise, and where the lofty ranges of Mount Yule and Mount Stanley offered the prospect of an equally rich and still less known exploring ground. Accordingly, in December 1874, he reached Somerset (Cape York) by way of Singapore, with the intention of settling at Yule Island, which he had before fixed upon as convenient head-quarters for the exploration of Southern New Guinea After some difficulty and delay he reached the island on March 17, and finding the natives friendly obtained permission to occupy some land and build a house Here he stayed till November, having with him a young Italian, two Cingalese, and five Polynesians, making large collections of natural history, exploring the island and the shores of the mainland, but being quite unsuccessful in his attempts to reach even the foot of the great mountains of the interior

This completes the first volume, which contains by far the most interesting matter both to the naturalist and to the general reader The second volume is devoted to a detailed journal of three successive voyages up the Fly River, the first in the missionary steamer *Ellangowan*, the two others in a small steam-launch, the *Neva*, lent him by the Governor of New South Wales On the second and most successful of these voyages D'Albertis penetrated to the very centre of the great southern mass of New Guinea, reaching the hilly country, but not the great central range of mountains, of which a few glimpses were obtained at a considerable distance.

The first impression produced by the careful perusal of these volumes is, that Signor D'Albertis has all the best qualities of an explorer—enthusiasm, boldness, and resource; a deep love of nature, great humanity, and an amount of sympathy with savages which enables him to read their motives and appreciate the good qualities which they possess To the character of a scientific traveller he makes no claim, and those who expect to find any sound generalisations from the results of his observations will in all probability be disappointed. Let us, however, by a few examples and illustrative passages, enable our author to speak for himself.

While residing at the village of Ramoi he became prostrated by fever, and was besides almost starving, for the natives would sell him nothing neither would they carry his baggage to enable him to return to Sorong Determining however not to die there without an effort, he sent for some of the chiefs to speak to him, and then grasping his loaded revolver assured them that unless they gave him men at once to assist him to leave the place not one of them should quit his hut alive The plan succeeded. One was allowed to go and fetch the men, the others remaining as hostages, and the revolver never left his hand till his baggage was all on board the canoe A little later when the travellers were on their way to Dorey, the native crew were very insolent, and boasted that when they reached their own country they would kill all the white men D'Albertis, hearing this, asked the man if he dared to repeat it, and on his doing so suddenly seized him by the throat and pitched him overboard. He was, of course, on board again in a moment, and instantly seized a bamboo to attack our travellers, but they exhibited their revolvers, and so cowed the whole crew that they became quiet and submissive for the rest of the voyage. An admirable portrait of one of these Dorey Papuans (Fanduri) is given, and the present writer can almost believe that he recognises in it one of his own acquaintances at Dorey in 1858.

More amusing was the way in which Signor D'Albertis made use of the aneroid on his journey to Hatam. His porters, who had agreed to take him there for a fixed payment, stopped at a village to rest, and on being told to go on, said, "This is Hatam, pay us our wages." He knew however, both by the distance and elevation, that that they were deceiving him, and told them so, but they again said, "This is Hatam, pay us How do you know that this is not Hatam?" He then took his aneroid out of his pocket, and laying his finger on a point of the scale, said, "Here is Hatam, this thing tells me where it is," and then explained that when they got higher up the mountain the index would move, and when they reached Hatam it would come to the point he had marked This astonished them greatly, but they would not believe it without

FIG 2—Fanduri, a Dorey Papuan

proof. So he let one of them carry it himself to the top of a small hill near, when they saw that the index had moved, and on coming down that it moved back againt This quite satisfied them. They acknowledged that the white man knew where he was going, and could not be deceived, so they at once said, "Let us rest to-day, tomorrow we will go to Hatam." Of course every man and woman in the village wanted to see the little thing that told the stranger where lay the most remote villages of the forest; and thus the traveller's influence was increased, and perhaps his personal safety secured.

In his second journey he provided himself with dynamite and rockets, which were very effectual in frightening the savages and giving him moral power over them. At Yule Island he was on excellent terms with the natives, on whom he conferred many benefits. Yet during his absence on an exploration his house was entered and a large quantity of goods stolen. In recovering these and firmly establishing his power and influence he showed great ingenuity. Calling the chiefs and other natives

together—who all pretended great regret at his loss, though the robbery must have been effected with their connivance—he told them that he was determined to have his property back, and that if it was not brought in twenty-four hours he would fire at every native who came within range of his house, which fortunately commanded a great extent of native paths, as well as the narrow strait between the island and the main land. He then made his preparations for a desperate defence in case he was attacked, loaded some Orsini shells and mined the paths leading to his house, so that with a long match he could blow them up without exposing himself. At the end of the twenty-four hours, nothing having been brought, he commenced operations by exploding five dynamite cartridges, which made a roar like that of a cannonade, the echoes resounding for several seconds. He then let off rockets in the direction of the native houses, and illuminated his own house with Bengal fire. All this caused terrible consternation, and the next morning the chief arrived with five men, bringing a considerable portion of the stolen goods, and trembling with fear to such an extent that some of them could not articulate a word. He insisted however that the rest of the goods should be brought back; and the next day, to show that he was in earnest, fired at the chief himself, as he was passing at a distance of 300 yards, being careful not to hurt, but only to frighten him. A canoe was also turned back by a bullet striking a rock close by it. The effect of this was seen next morning in another visit from the chief, with five complete suits of clothes, axes, knives, beads, and other stolen articles. Much more, however, remained, and D'Albertis took the opportunity of impressing them thoroughly with his power. He first asked them to try to pierce a strong piece of zinc with their spears, which were

FIG. 3.—Epa, a Village of the Mahon-papuans.

blunted by the attempt, while he riddled it through and through with shot from his gun. He also sent bullets into the trunk of a small tree a hundred yards distant, showing that a man could not escape him. They had been seated on a large stone near his house, which he had mined. He now called them away, and having secretly lighted the match, told them to look at the stone. A tremendous explosion soon came, and the stone disappeared. The natives were too frightened to move, and begged him to have pity on them, promising to restore everything. A great hole was seen where the stone had stood, while some of its fragments were found a long way off. For twelve days more he kept up a state of siege, turning back all travellers and many canoes by rifle-balls in front of them, but never hurting any one. Then another large instalment of his goods was brought, leaving little of importance, and ultimately he recovered almost everything. During the whole of this time he never hurt a single person or did any damage to their property, but succeeded in getting back his own by impressing them with his, to them, superhuman power. The result was that after eight months' residence he parted from these people on the best of terms. They all embraced him, and most of them shed tears, while their last words were "*Maria rau! Maria rau!*" "Return, Maria! Return, Maria!"—that being his second name, by which they had found it most easy to call him.

As a fearless capturer of snakes Signor D'Albertis rivals, if he does not surpass, the celebrated Waterton; indeed he seems to like them rather than otherwise. At Yule Island the natives had found a large snake under a tree, and all ran away from it, crying out, and this is his account of what happened.—

"At last I went to the natives and tried to ascertain

the cause of their conduct, and they made me understand why they had fled. I then returned to see the snake myself, which in fact I did, although two-thirds of its length were hidden in a hole in the earth His size was such that I concluded he could not be poisonous, and I at once grasped him by the tail. While dragging him out of his lair with my two hands I was prepared to flatten his neck close to his head with one foot the moment he emerged, so that he should not have the power of turning or moving. My plan succeeded perfectly, and while the snake's head was imprisoned under my foot I grasped his body with my hands, and, as though I had vanquished a terrible monster, turned towards the natives with an air of triumph They, struck with terror, had looked on at the scene from a safe distance. I must confess that the snake offered little resistance, although it writhed and twisted itself round my arm, squeezing it so tightly as to stop the circulation, and make my hand black. I remained however in possession of its neck, and soon secured it firmly to a long thick stick I had brought with me. I then gave the reptile to my men to carry home" This serpent was thirteen feet long, whereas the one Waterton caught single-handed was but ten feet, though it might have been equally powerful. This snake was kept alive and became quite tame, and when the natives saw D'Albertis kiss its head and let it coil round his legs they howled with amazement and admiration Six weeks after the capture he writes.—"My snake continues to do well; it has twice cast its skin, is well-behaved and tame, and does not attempt to escape, even when I put it in the sun outside the house, and when I go to bring it in, it comes to me of its own accord. It never attempts to bite, even when I caress or tease it While I am working I often hold it on my knees, where it remains for hours, sometimes it raises its head, and licks my face with its forked tongue. It is a true friend and companion to me. When the natives bother me it is useful in putting them to flight, for they are much afraid of it; it is quite sufficient for me to let my snake loose to make them fly at full speed" He kept this serpent for nearly six months, and latterly another of the same species with it, till at last both escaped, and he mourns their loss as of dear friends, adding, "for I loved them and they loved me, and we had passed a long time together."

The furthest village on the mainland visited by D'Albertis was Epa, where he lived five days, and of which he gives a very pleasing account. It is about 1500 feet above the sea, but a very short distance from the coast. The village is surrounded by a strong double stockade, and the people appear to be good specimens of the superior Mahori-Papuan race By the aid of these people it would probably not have been difficult to penetrate to the mountains of the interior, but our traveller was drawn away by the opportunity of exploring the Fly River, and has left the exploration of this grand mountain range with its rich natural treasures for some future exploration or some other explorer. Having thus sketched the outline of Signor D'Albertis' eastern voyages and indicated his main characteristics as a traveller and an author, let us see what he has to tell us about the people among whom he travelled.

ALFRED R WALLACE

(To be continued.)

PROF J. C. WATSON.

WE regret to have to record the death of Prof Watson, for many years director of the Observatory of Ann Arbor, Michigan, and later of the new Observatory established at Madison, Wisconsin, under the auspices of General Washburne

James Craig Watson was born on January 28, 1838, in Elgin County, Canada West, of American parents who were residing in Canada at the time of his birth While he was still a boy they removed to Ann Arbor, where at fifteen years of age he entered the University as a classical student, but his mathematical bias soon became evident He studied astronomy under Prof Brunnow, who was then in charge of the Ann Arbor Observatory, and Professor of Astronomy in the University, and while the latter was director of the Dudley Observatory at Albany, Watson occupied his place at Ann Arbor In 1860, when Prof Brunnow returned there, he was transferred to the Chair of Physics, which position he held until Prof Brunnow finally severed his connection with Ann Arbor in 1863, when Watson was again appointed director of the Observatory From this time his attention was chiefly directed to the discovery of minor planets, with which view he formed charts of very small stars, he had also in view the possible detection of an ultra-Neptunian planet, and it has been stated that latterly he had been more particularly working with this object, and had removed from Ann Arbor to Madison, to avail himself of the more powerful instrumental means at the latter place, where the refractor has an aperture of 16 inches, that of the Ann Arbor telescope being 12½. Watson added twenty-three members to the group of small planets, his first discovery being that of Eurynome in September, 1863

In 1870 Watson proceeded to Sicily at the head of a Commission appointed by the United States Government to observe the total eclipse of the sun on December 22, and in 1874 he went to Pekin in charge of a similar Commission for the observation of the transit of Venus. While at Pekin he discovered No 139 of the minor planet group, and it was stated at the time that the discovery was effected entirely through Watson's extraordinary recollection of the configuration of the small stars in the neighbourhood where the planet was situated (R A 0h. 58m. 15s, Decl. $+ 10° 44'$) A member of the Imperial family who had been asked to name the planet, called it the "Hope of China", *Juewa*, the name by which it has since been known, being an Anglicisation of the Chinese term.

Watson's observations of two objects during the totality of the eclipse of July 29, 1878, which he considered to be intra-Mercurial planets, will be fresh in the recollection of the reader there is no doubt that whatever opinion may have been entertained by other astronomers, he was himself convinced that he had met with planetary bodies, and he stoutly defended his opinion against the doubts raised in his own country

Watson was the author of a valuable work upon Theoretical Astronomy, published in 1867, upon which his reputation as an author mainly depends. He was a member of the principal scientific institutions of the United States, and his merits were acknowledged by several of the European Academies; he received the Lalande Medal of the Paris Academy of Sciences in 1870 for his numerous planetary discoveries.

The death of Prof Watson took place somewhat suddenly on the morning of November 23, at his residence on Observatory Hill, Madison, Wisconsin, and is attributed to intestinal inflammation, following upon a severe cold, in an overstrained condition of body he had been working hard as usual at night, while superintending the completion of the Observatory buildings by day He was buried at Ann Arbor on November 26; memorial services were held in the University hall, and were attended by a body of between seven and eight hundred students, and a large concourse of the general public, addresses being delivered by the President and several Professors of the University, of which the Ann Arbor and Detroit journals furnish lengthy reports.

NOTES

THE subscription opened by the Paris Academy of Sciences for raising a statue to M. Becquerel, the celebrated electrician, is almost closed, having produced 15,000 francs, only 1500 francs more are required. Those wishing to subscribe should send their contributions to M. Maindron, at the Academy of Sciences, as early as possible.

LAST week M. Moll, the *doyen* of the Professors of the Conservatoires des Arts et Métiers, died in Paris. He was the oldest teacher of agriculture and one of the first, having been one of the staff of the celebrated Rouville *ferme-école*, established about sixty years ago.

THE Nestor of German bryologists, Prof Ernst Hampe, died at Helmstedt on November 23 at the age of eighty-five years

ON Nov. 23 the first section of the St. Petersburg Academy of Sciences (physico-mathematical sciences) had to choose a member in chemistry, and an influentially-signed presentation recommended Prof. Mendelejef to the choice of the Academy. The Academy would certainly have done itself honour in choosing a man of such eminence in science, but we regret that Prof. Mendelejef was not elected This is held locally to show that the Academy is influenced in its selection by other reasons than the value of a candidate's scientific work. The impression on the public in general, we believe, is very unfavourable to the Academy, not a day passes, we are informed, that Prof Mendelejef does not receive letters and telegrams from men eminent in science expressing admiration for his works. Many scientific societies have made him an honorary member, and only the other day the University of Moscow did the same !

AN interesting collection is being made by M Dumas of medals commemorative either of scientific men or scientific discoveries The number already collected is far greater than had been expected.

LIEUT. JULIUS PAYER, one of the leaders of the Austrian North Polar Expedition of 1872-74, has settled at Munich with the intention of devoting himself exclusively to the art of painting.

THE central committee for the erection of a Spinoza monument at the Hague have, before their dissolution, resolved to utilise the remaining balance of funds in their hands for publishing a new and handsome edition of the complete works of the great philosopher. Doctors J. van Vloten and J. P. N. Land have been commissioned to prepare the new edition. In the interest of this laudable undertaking the friendly request is now addressed to all librarians and possessors of autographs to communicate with these gentlemen regarding any autographs of Spinoza which may be in their possession, in order to render the edition as complete as possible. Communications are to be addressed to the publishing firm of Martinus Nijhoff at the Hague

A STRONG shock of earthquake was felt at Wiesbaden on the night of the 8th instant, at eleven o'clock; the shock was directed from north to south. A strong subterranean noise preceded it, and a violent wind of short duration was observed. Another shock is reported from Saxony A fresh violent shock lasting two seconds occurred at Agram at twenty-seven minutes after midnight of the 7th. Subterranean rumblings followed the shock and continued to be heard throughout the night. As on the last occasion the shock was accompanied by distant storms and preceded by a slight vibration On Wednesday night last week there was a strong earthquake shock at Agram which lasted six seconds. It was preceded by a loud rumbling. On the day previous the earth trembled for an hour together. That of Wednesday night was the strongest shock since the first. Two walls fell in and the houses shook. On Thursday evening last six slight shocks were felt at Vienna. At Agram there were two violent shocks at half past two and half-past three o'clock in the morning. A shock of earthquake was felt at Brescia on the afternoon of the 10th, accompanied with a rumbling noise.

PROF. RUDOLPH FALB gave a lecture in the Vienna Gewerbe Museum on November 27, in which he said that earthquakes are subterranean volcanic outbreaks, produced by the cooling action of the hot liquid interior of the earth and the attraction of the sun and moon. In support of this view he urged that most earthquakes occur at the time when the sun is nearest us, viz, in January, fewest in June, also the number of earthquakes increases in the months of April and October, because of the stronger attraction of the sun on March 21 and September 23 He said further that in the period December 16-30 this year fresh earthquakes might occur at Agram.

A NEW and somewhat bold hypothesis as to the cause of earthquakes has been propounded by Dr. Novak in Pesth. He considers that, besides the rotation of the earth on its axis and its revolution round the sun, a multiplicity of motions of the earth appear in space, in virtue of which the earth's axis, and with it the equator, shift their position. This causes a variation of the forces influencing the earth's form (centrifugal and centripetal force), and the earth has the tendency to adapt itself to this change He also considers a change of form of the earth to occur through the shifting of the pole and the equator, and that this may have effect some time afterwards, where the earth's crust is weak.

WE are requested by the Sunday Society to announce the following arrangements for the Sunday opening of the Winter Exhibition of Oil Paintings at the Hanover Gallery, New Bond Street, by permission of the proprietor, Mr. Weil. On Sunday, December 26, the Gallery will be open to the Members of the Society, and on the two following Sundays the public will be admitted by free tickets, which will be issued to those applying by letter and sending a stamped and addressed envelope to the Honorary Secretary, 8, Park Place Villas, W On each Sunday ticket-holders will be admitted from 4 o'clock till 7 30 p.m., and the gallery will be closed at 8 o'clock. On the reassembling of Parliament the Society will press its claims upon both Houses of the Legislature by bringing forward the following resolution :—"That inasmuch as all opposition to the action of Her Majesty's Government in opening on Sundays the National Museums and Galleries in the suburban districts of London and in Dublin has entirely ceased, owing to the good results which have followed such opening, this House is of opinion that the time has now arrived for extending this action to all institutions of a like character, it having been most conclusively shown that large numbers of the people rejoice in every opportunity that is afforded them of spending Sunday intelligently and with due regard for its preservation as a day of rest and cessation from ordinary work and amusement."

SOME information regarding the observatory at Nice, now in course of construction through the munificence of M. Bischoffsheim, is given by M. Tissandier in *La Nature*. Some 35 hectares of ground have been acquired. The situation is a few kilometres north-east of Nice, near the road from Corniche over the Mont des Mignons (or Mont Gros), and 375 m. above the sea There are to be two large dwelling-houses for astronomers and for accommodation of visitors. One is already finished, and M. Thollon has there done some excellent work in spectroscopy. More than 250 workmen are at present busy on the buildings. Some of the instruments will shortly be ready The whole is being organised under the auspices of the Bureau des Longitudes.

The Observatory will comprise at first two equatorials, one meridian, and several accessory instruments. One of the equatorials will probably be the largest astronomical apparatus in the world. Its focal distance will be 18 metres, and its aperture 0·76 m. The cupola will have a diameter of no less than 22 m. The construction of the object glass is entrusted to MM. Paul and Prosper Henry of the Paris Observatory. The instrument alone will cost about 250,000 francs, and the cupola will be correspondingly expensive. The total cost of the Observatory will exceed two million francs.

AN interesting pamphlet on the subject of the introduction of hypotheses in school education has been published by Dr. Hermann Muller of Lippstadt (Bonn, Strauss). Dr. Muller writes in self-defence and in reply to Prof. Virchow, whose controversy with Prof. Hackel on this subject some years ago will be remembered.

AMONG other useful matter in the "British Almanac and Companion" for 1881 is a summary of the science of the past year, by Mr. J. F. Iselin, which is good so far as it goes, but that is necessarily not very far. There is also an article on "Weather Forecasting," by Mr. R. H. Scott, and a "Sketch of the History of the Royal Observatory, Greenwich," by Mr. W. T. Lynn.

THE Report of Mr. Morris, the Director of Public Gardens and Plantations in Jamaica, on the financial results of the last consignment of Cinchona barks sent to the London market, is extremely satisfactory, inasmuch as it shows the superiority of Jamaica barks over those of Ceylon, as indicated by the prices realised. The consignment referred to in the present Report consisted of eighty-one bales, in which the several species under cultivation were represented, crown bark from *C. officinalis* and red bark from *C. succirubra* forming by far the largest proportion. The total amount realised for these eighty-one bales was 1313*l.* 11*s.* 7*d.* For all the different kinds, whether "quill," "trunk," "root," or "twig" bark, the prices realised were in excess of those obtained for the same kinds of Ceylon barks, to the extent even in some cases of 2*s.* 9*d.* per pound. Mr. Morris draws attention to the fact that from the recent sales the relative merits of the two principal species under cultivation, namely, the crown or grey bark (*C. officinalis*) and the red bark (*C. succirubra*) have become very distinctly marked. The first named species has proved to be a most valuable product, and whatever changes and fluctuations may ultimately take place in view of the more extensive cultivation of Cinchona in different parts of the world, high-class bark of this nature must always command good and remunerative prices. The conclusion arrived at is that the conditions of soil and climate of certain parts of Jamaica are "eminently favourable to the production of the best qualities of these valuable products, and as large tracts of land and the necessary labour are now available, there are only wanting sufficient capital and energy to overcome the initial difficulties of this enterprise."

THE buds of the second vegetation in Paris which we noticed in October were killed by the frosty weather in the beginning of November, but a new vegetable phenomenon has been seen in the Champs Elysées. Owing to the exceptional hot weather prevailing in December new leaves have been observed on a few trees, and were flourishing at the date of our most recent observations.

THE Bill relating to the forthcoming exhibition of electricity in Paris has been presented to the Chamber. M. Cochéry asks for a credit of 300,000 francs—150,000 for the exhibition and 150,000 for the Congress and experiments. A guarantee fund of 20,000*l.* has been signed by fifty persons.

A USEFUL pamphlet on Bedroom Ventilation has been published by Mr. Lawson Tait of Birmingham.

THE *American Entomologist* has been incorporated with the *American Naturalist*.

THE rare phenomenon of an inverted rainbow was observed at Innsbruck on November 25 at 8.45 a.m. The end points of the semicircle, the centre of which was the sun, rose and moved westwards with the latter for some thirty minutes. The phenomenon then vanished.

A VALUABLE discovery has been made at Jochenstein, near Obernzell (Bavaria). A farmer of Jochenstein had frequently noticed a stone plate, of some 1½ metres square, in the centre of a wood belonging to him. He had the plate raised recently, and under it were found six head-rings, four spiral bracelets, each showing nine twists, and two battle-axes. All the objects are of bronze and capitally preserved.

THE second part of "The Scientific English Reader" (Leipzig, Brockhaus), edited by Dr. F. J. Wershoven, the first part of which we have already referred to, contains extracts relating to machinery and mechanical technology.

THE fourth part of Dr. Dodel-Port's excellent "Atlas of Physiological Botany" has just been published. The six plates it contains are in every respect equal to those of the former numbers. They comprise (1) *Volvox minor*, germ-history of the oospore (this plate forms the supplement of the *Volvox globator* plate in part 1), (2) *Equisetum Telmateja*, sporangia and spores; (3) *Passiflora cœrulea* and *P. cœruleo-alata*, (4) *Selaginella helvetica*, with macro- and microsporangia, macro and microspores; (5) *Polytrichum gracile*, male and female plants, moss-fruit and its anatomy, spores and germinating spores, (6) *Narcissus poeticus*, seed-bud in longitudinal section at the time of fertilisation. These drawings are made according to the latest researches on the fertilisation of phanerogamic plants. Parts 3-5 of the same authors' "Illustrirtes Pflanzenleben" will also shortly be published.

AMONG the special papers in the *Annuaire* of the Brussels Observatory for 1881 are the following:—"What is the Climate most favourable to the development of Civilisation?" "Physical Phenomena accompanying the Transits of Mercury," by M. Niesten; "Nomenclature of existing Public Observatories"; "The Asteroids," by M. Niesten; "The Isthmus of Panama."

THE last Calcutta *Gazette* contains some official correspondence regarding the insect lately discovered in Monghyr, which threatens to become very destructive to the rice crops. The specimens forwarded to Mr. Wood Mason, deputy superintendent of the India Museum, have been identified by him as belonging to the genus *Cecidomyia* and as related to the Hessian fly which ravaged the wheat-fields in the United States. This genus, Mr. Mason says, has never before been found in India, and he proposes to call the species *Cecidomyia oryzæ*, or the rice-fly. He goes on to say that it is likely to prove a most formidable pest, and recommends that the district officers should be instructed to make further inquiries and carefully watch its progress.

A RECENT number of the *Golos* contains an interesting letter from Tiflis describing the enormous labour bestowed during the summer upon the destruction of the grasshoppers. The work was carried on for about three months, and occupied in one district (Gori) no less than 20,000 people per day. More than half these people had been summoned from the neighbouring districts of Achalzych, Ossetia, and Imeretia. Thanks to the colossal efforts thus made only 2 per cent. of the total crops of the district were destroyed by the grasshoppers. Many million roubles worth of hay and corn were saved by this work. On the other hand the organisation of the whole cost the Russian Government some 200,000 roubles, and many thousand acres of fields and gardens have been utterly neglected by the population to whom they belong.

A Rhenish Fishery Society has just been founded at Cologne. It will direct its attention not only to the Rhine fisheries, but its programme is a most universal one, comprising even the furtherance and support of ichthyological research as well as the establishment of ichthyological stations in various countries.

Mr. Baller of the China Inland Mission has lately made a journey in the little-known province of Kweichow at the time when the people were engaged on their opium harvest, and he thus describes the process :—A small three-bladed knife is used to make an incision in the poppy-head as soon as the petals fall off. The drop or two of milky juice that oozes out is after a little while scraped off with a small curved knife into a bamboo tube, and a fresh incision made. The process is repeated until the supply is exhausted. The juice thus collected is dried in the sun, when it turns jet black, and is then ready for the market

OUR ASTRONOMICAL COLUMN

The Comets of Hartwig and Swift.—MM. Schulhof and Bossert have investigated the elements of comets 1880 *d* and *e*, discovered respectively by Dr Hartwig at Strasburg on September 29, and Mr Lewis Swift at Rochester, New York, on October 11. Prof. Winnecke had conjectured that Hartwig's comet might have been identical with the comets of the years 1382, 1444, 1506, and 1569, with a period of revolution of 62¼ years MM. Schulhof and Bossert formed six normal positions between September 30 and November 29 from observations at Paris, Strasburg, Berlin, Leipsic, Kiel, Kremsmunster, Lund, Florence, Marseilles, O'Gyalla, Clinton, and Washington, and on varying the distances from the earth at the first and fifth place until the other normals were represented as closely as possible, arrived at an elliptical orbit, but with a period of 1280 years: this result is necessarily uncertain under the circumstances, but it nevertheless appears to render so short a revolution as 62¼ years in the highest degree improbable

With respect to Swift's comet, taking as the fundamental data the Odessa observation on October 31, a mean of Dunecht, Paris, and Strasburg on November 9, and an observation at Paris on November 27, it is found that, assuming only one revolution to have been accomplished between 1869 and 1880, or that the period is 10·96 years, the middle place cannot be represented with sufficient precision, when the error is diminished in longitude, it is increased in latitude. On the hypothesis that the period is 5½ years, or that two revolutions are included in the above interval, the error in latitude is greatly diminished, but still exceeds thirty seconds of arc. This, while indicating that the second hypothesis is more probable than the first, is regarded by MM. Schulhof and Bossert as rendering so short a period as 3⅔ years possible, though it is admitted that it may well be due to errors of observation It must be borne in mind that the comet has always presented itself as a faint diffused object, without that degree of condensation necessary to insure precise observation The following is the ellipse of 5½ years' period —

Perihelion passage, 1880, November 8·00011 G M.T.

	°	′	″	
Longitude of perihelion	43	4	33	M Eq. 1880·0
,, ,, ascending node	296	51	33	
Inclination	5	23	32	
Angle of excentricity	41	3	25	
Logarithm of semi-axis major	0·492684			

With these elements the perihelion distance will be found to be 1·0671, and the aphelion distance 5·1518, and the heliocentric latitude at aphelion − 4° 6′·6, whence we find the distance from the orbit of Jupiter to be 0·53.

MM. Schulhof and Bossert propose to continue their investigation when further observations are available: meanwhile it may be remarked that their ellipse of five and a half years is likely to afford positions sufficiently near the truth to insure the observation of the comet as long as it is within reach of our telescopes, and it may be suggested to those who are in possession of powerful instruments that they will render an important service in determining places of this comet as long and as accurately as practicable

The November Meteors.—Notwithstanding much interference from clouds the observers at Moncalieri, who watched for meteors during the nights of November 12-14, consider that they obtained evidence of the increasing density of the Leonid-stream, thus confirming observations made last year in England and the United States. One of these meteors appeared larger than the planet Jupiter, with an intense blue light, and a bright train of the same colour It is added: "La lumière zodiacale d'opposition était très brillante vers l'orient, sur le fond pur de ciel, s'élevait jusqu'au delà de la queue de Lion."

Near Appulse of Jupiter to a Fixed Star.—On the evening of November 20 Jupiter must have approached very near to the star B.D. + 2° No. 97, rated 7·7 in the *Durchmusterung*, and 7·9 on December 17, 1856, when it was observed on the meridian at Bonn, indeed the resulting place of the star would bring it almost into contact with the limit of the planet about the time of conjunction in right ascension (9h 4m.), but small errors of the star's position and tables of Jupiter may have combined to leave it at an appreciable distance from the limb, perhaps some reader of Nature may have determined micrometrically the nearest approach. The apparent place of the star on November 20 was in R.A. 0h. 38m. 49·44s., Decl. + 2° 32′ 59″·9.

BIOLOGICAL NOTES

Anabæna living in Botrydium.—It is now well known that many plants belonging to the group of the Nostocs flourish within the cells of other plants Thus they are to be found in the petioles of the leaves of Gunnera, in Lemna, in Anthoceros, in Blasia, and in Azolla, and it was to be expected that they would equally find themselves at home in the cells of even more lowly organised plants An instance of this latter, not without interest, has been noticed by Dr L Marchand, who recently collected a Botrydium at Montmorency, which, on being examined under the microscope, was found, instead of containing the usual mass of granular chlorophyll, to be filled with a chain of moniliform filaments, presenting all the characters of the chaplets of a Nostoc or Anabæna. These filaments were composed of cells, some oblong with yellowish heterocysts, and they did not fill the entire cavity of the Botrydium cell, but seemed to adhere to its inner walls. The Botrydia plants were perfect; the root like prolongations, as well as the rest of the plant, were perfectly closed. How then did these foreign bodies get in? This is not a question easy to answer, but it is one well worthy of being investigated. Dr. Marchand calls attention to the remarkable figure of Mr F. Parfitt in "Grevillea" (vol. i. p 103, pl vii), in which there is now little doubt, with the light thrown on the subject by Dr. Marchand's specimens, that there is represented our common species of Botrydium with a parasitic, or better, an endophytic Anabæna. No doubt the cells of the Anabæna in Parfitt's figure are badly represented, but the observation made in Parfitt's paper would seem now not to be without a special interest of its own.

Mesembrianthemum not Mesembryanthemum.—Prof. Asa Gray, in the *Botanical Gazette* (Indiana), vol. v. Nos. 8 and 9, p. 89, thus writes:—This word is properly written Mesembrianthemum, by Jacob Breyne, who made the name, and by Dillenius, who took it up, both giving the derivation from *Mesembria*, mid-day, alluding to the time in which the blossoms open. But both Breyne and Dillenius themselves very often wrote it Mesembryanthemum, Linneus, adopting this latter, became consistent by making a wrong and far-fetched derivation to match the orthography Among systematic writers Sprengel almost alone keeps to the correct orthography, but Webb insists on it. The younger Breyne, in his edition of his father's "Prodomus," has a note about it (p. 81). He mentions an excuse for changing the orthography, namely, "that some species do not open their blossoms at noontide," but intimates that Linneus' derivation from the insertion of the corolla around the middle of the germ is open to the same objection. Prof. Asa Gray adds, "if heeded, this kind of objection would be fatal to very many generic names."

Chlorophyll in the Epidermis of Plants.—Adolf Stohr contributes to the *Scientific Proceedings* of the Vienna Academy a very interesting paper on the occurrence of chlorophyll in the epidermal tissue system of the leaves of flowering plants. He sums up a detailed account as follows:—While the epidermis of the aquatic submerged Phanerogams is usually regarded as containing chlorophyll, the epidermis of the green organs of the terrestrial Phanerogams is, on the contrary, considered to be

destitute of chlorophyll. This at least is the most prevalent view. Exceptionally, submerged Phanerogams are found with an epidermis destitute of chlorophyll, and there are also some exceptions to the general rule quoted about the leaves of terrestrial Phanerogams. Now it happens that the at present prevailing view is only right in one respect, for up to the present, observations prove the regular appearance of chlorophyll in the outer layer of submerged Phanerogams. The second half of the prevalent view should be completely reversed, for the appearance of chlorophyll in the epidermis of the green organs of Phanerogams is the rule, and with few exceptions. The results of Stohr's researches lead to the following:—1. The epidermis of the green organs of the broad-leaved Gymnosperms, and of by far the most of the terrestrial Phanerogams, contains chlorophyll. 2. Chlorophyll appears regularly to be absent from the green organs of the needle-leaved Gymnosperms and the terrestrial Monocotyledons. 3. Chlorophyll is in most cases only to be found in the under surface of the leaves, but is also to be met with in the leaf-petioles and stipules. It remains in such position during the whole life of the organ. 4. Chlorophyll is seldom to be found in the upper and lower surfaces of the leaves at the same time. In most cases one can see that the chlorophyll of the cells of the epidermis of the upper surface of the leaf is quickly destroyed upon its formation, by the effect of a too intense light. 5. So far as the process of the evolution of the chlorophyll bodies was observed, the latter showed themselves as starch-chlorophyll bodies. M. Stohr gratefully acknowledges that these investigations were undertaken at the suggestion of Prof. Wiesner, the author of a memoir, "Ueber die naturlichen Einrichtungen zum Schutze des Chlorophylls der lebenden Pflanze." The leaves of nearly one hundred species of plants were carefully examined, and full details of these examinations are given in the tables that accompany M. Stohr's memoir. The investigations were carried out in the botanical-physiological laboratory of the University of Vienna. (*Sitzungsberichte d. k. Akad. Wissenschaften—mathem.-naturw. Cl.*, 79 Bd., S. 87.)

Blood Vessels of Valves of the Heart.—Recent researches by Dr. Langer (Vienna Acad. *Anz.*) prove that several mammalian genera (pig, dog, bullock) have a fully-formed blood-vascular system both in the semilunar and the atrioventricular valves. On the other hand an examination of about 100 human hearts (of children and adults) discovered blood vessels in the heart-valves only in one case, that of a woman of sixty, in whom they were evidently the result of a pathological process. Dr. Langer explains the difference by a difference in the mode of formation of the valves.

Light and the Transpiration of Plants.—Dr. Comes (Naples Academy) finds, *inter alia*, that light favours transpiration; that a little after midday transpiration is at its maximum; that, other things equal, that organ transpires most which is most intensely coloured, and it emits most water when exposed to that part of the solar spectrum where it absorbs most light; and that only those luminous rays which are absorbed favour transpiration of an organ (not the inactive rays); so the transpiration is minimum under the rays coinciding in colour with that of the organ, and maximum under the complementary rays.

Pinguicula Alpina.—Prof. Klein of Buda-Pesth publishes in the last part of Cohn's *Beiträge zur Biologie der Pflanzen* an interesting memoir on this plant. 1. It appears in two forms: one has bright green leaves, the other has more or less reddish-brown coloured ones. These forms however appear only to possess the value of local varieties. 2. *Pinguicula alpina* is, like the other species of Pinguicula, an insectivorous, *i.e.* flesh eating plant, but is partly also a plant eating one. 3. Its roots are simple, *i.e.* they do not branch, and they possess notwithstanding a pericambium. The cells of the bast layer have handsome, for the most part doubly-ridged longitudinal walls, and are the first formations that differ from the primary meristem of the end of the root. The greatest part of the root remains in respect to the tissue formation in an undeveloped and almost embryonic condition. 4. The caulome contains between the pith and bark a vascular ring which is characterised by very short-jointed vessels; these joints are bound together at the points of contact, and their cross walls are broken through by one single circular opening. The bundles of vessels belonging to the roots spring partly out of the caulomic vascular ring, partly out of the leaf-spur. 5. The original bending in of the edges of the leaves can be regarded as an advantageous arrangement in respect to the catching of insects, as insects cannot easily get over the edge of the leaf, and can therefore also be generally caught under it. 6. The cells of the epidermis of the leaf contain no chlorophyll, but the green-leaved specimens contain a colourless sap and the red-leaved ones a reddish sap. Besides they always possess a cell nucleus in which crystalloids are to be found. 7. The edge of the leaf is transparent, and consists of a single row of epidermis cells. 8. The epidermis of the leaves contains as well on the upper as on the lower side tolerably numerous stomates, which are only wanting on the outermost edge. Their manner of formation corresponds mostly to that observed in Thymus; it shows however some deviations. The stomate is surrounded by a narrow edging which is more strongly cuticularised than the outer walls of the epidermis cells. The cells of the stomates contain no crystalloids, but only a few very small chlorophyll bodies. 9. The epidermis of the upper surface develops two kinds of glands with and without stalks. The glands with stalks consist of a basal cell projecting above the epidermis; out of this proceeds a one to four-celled half spherical columella, on the top of which a glandular body, consisting of a layer of radially-placed cells, is placed cap-like; the stalkless glands are similarly built, only the stalk is wanting, the columella is conical, and the glandular body does not as a rule project more than half over the epidermis. The process of development is similar in both glands. 10. Stalkless glands appear also on the lower side of the leaf. They are only feebly developed, and their cap portion hardly projects over the epidermis. From their presence it can be deduced that the various kinds of Pinguicula once only possessed stalkless glands; from which in process of time both the stronger developed stalkless glands and those also with stalks became developed on the upper side of the leaf, by which the capacity of the leaves for catching and digesting insects was at the same time perfected. In connection with this, one can infer a somewhat similar theory about Utricularia and Aldrovanda, and even about Dionæa and Drosera. 11. The bundles of vessels belonging to the leaves are branched out in netlike veins, and anastomose chiefly with one another. The veins at the ends unite near the edge of the leaf into a sympodial layer, from which numerous veins go out directed to the edge of the leaf and end in enlarged spirally thickened cells, which cells sometimes border directly on the epidermis cells belonging to the edge of the leaf or are separated from them by one or more cells. 12. The tracheal vessels of the leaves, as well as of the other parts of *Pinguicula alpina* never contain air, but either a watery fluid or a yellowish-brown resinous-looking substance. This circumstance, together with the strange branching of the tracheal vessels in the edge of the leaf particularly adapted to catching insects seem to prove (or show) that the tracheal vessels serve for the transport of a substance that stands perhaps in direct connection with the function of the leaves. 13. The mesophyll cells form among one another tolerably large interstices filled with air, and contain generally chlorophyll bodies in abundance. 14. Starch is to be found in the chlorophyll bodies of *P. alpina*, and also in the small stems and roots of the hybernating plants, when it appears in small compressed nuclei. 15. Glands with and without stalks appear in the flower stalks as well as in the flowering parts.

GEOGRAPHICAL NOTES

At a meeting of the Geographical Society on Monday evening Capt. T. H. Holdich, R.E., of the Survey of India, read a very interesting paper on the geographical results of the Afghan campaign, in which, after giving a sketch of the features of the country, he summed up the additions lately made to our knowledge. These are very considerable, for in the last two or three years he and Major Woodthorpe with their staff have surveyed and mapped from 25,000 to 30,000 square miles of country. Some of the more important facts ascertained are the facility with which practicable roads can be made through the passes of Afghanistan, and the comparatively low elevation of those of the Hindu Kush, which, according to Capt. Holdich's view, would offer no real barrier to the advance of a properly-equipped army. Capt. Holdich hinted that the further mapping and survey of the country were being continued by native explorers attached to the Survey of India, and he thought that in a few years' time it would be known from end to end, and that our surveys would then join on to those of the Russians north of the Hindu Kush. Capt. Holdich remarked also on the curious intermingling of races in some parts of Afghanistan, and in the ensuing discussion Mr. Blanford, late Director of the Geological

Survey of India, made some valuable observations on certain points connected with soil-formation, &c., in Central Asia

UNDER the title of "Die geographische Erforschung des afrikanischen Continents von den ältesten Zeiten bis auf unsere Tage," by Dr. Philipp Paulitschke, Messrs. Brockhausen and Brauer of Vienna have published a volume of 320 pages, containing a brief but full sketch of the progress of African exploration from the earliest times down to the present day. Its special value consists in the detailed bibliography of the subject contained in the footnotes on every page, which must be of the greatest service to the student of African exploration and geography. There are occasional slips, as when Mr. Monteiro's book on "Angola and the River Congo" is entered under "Monteiro," as published in New York in 1875, and again under "J John," as published in London in 1876 But such blunders are wonderfully few About 1500 names are referred to altogether.

DR. LENZ, on November 22, was at St. Louis, whence he was going to Tangier

AS a memorial of the work performed in the *Vega*, a "*Vega* Fund" has been raised by subscription in Sweden to encourage further geographical research. The sum raised is 35,000 crowns, which will be intrusted to the Swedish Academy of Sciences, and the interest either employed at once or be allowed to accumulate for a term of years Only natives of Sweden, Norway, Denmark, and Finland will be entitled to receive the benefit of the fund.

TWO important expeditions are soon to be sent into Central Africa, under the auspices of the Algerian Missionary Society, which already has stations at the northern ends of Lake Tanganyika and the Victoria Nyanza One will go from Zanzibar, and the other will ascend the Congo.

THE INFLUENCE OF PRESSURE AND TEMPERATURE ON THE SPECTRA OF VAPOURS AND GASES[1]

IN the course of my inquiry last year into the homology of the spectral lines of chemically-related elements I occasionally made the observation that the two strongly-marked red lines which bromine in the fluid state gives when the spark is taken from it in De la Chanal's fulgurator grow very feeble or entirely disappear in the spectrum of the rarefied vapour in the Geissler-tubes, while other lines not previously seen become visible. It appeared to me of interest to inquire more particularly into the changes of the spectrum of one and the same element, as these changes are naturally of the greatest importance in the comparison of chemically-related elements, and with this view I addressed myself to the problem of the changes of spectra at higher pressures.

According to Wullner's well-known experiments, which only deal with the three permanent gases, hydrogen, oxygen, and nitrogen, the spectral lines of the second order grow broader with higher pressure, and at the same time a continuously illuminated background is to be observed This phenomenon, however, presents even in the three permanent elements the greatest difference Thus, while the lines in the hydrogen spectrum become easily broader even under moderate pressure, those in the spectrum of nitrogen do not expand. Therefore it occurred to me that a comparative investigation, which would extend to as many elements as possible, would be desirable, inasmuch as it encouraged the hope that by this means one could arrive at a law, perhaps even at an explanation, of these phenomena.

I now venture to present to the Academy a report of my experiments as far as they have gone, reserving a full account till their completion.

In my experiments I have treated the most volatile of the metalloids, and among the metals have included quicksilver and sodium. I will in due time give a full account of the apparatus and methods which I employed in my experiments, but at present I must confine myself to a statement of the results already ascertained.

The spectrum of the three halogens, at higher pressures, exhibits in each case the same peculiarities. The lines have the appearance of merging into each other, and without showing an expansion into bands, they become occasionally somewhat broader. There is a steadily luminous background which becomes brighter when the pressure is increased, and which is often more intense than the lines themselves. This latter circumstance is frequently seen in the case of iodine, where the continuous spectrum finally covers all the rest In the case of chlorine and bromine single lines are always distinguishable from the continuous surrounding light The appearance of certain lines in the red field in chlorine and bromine which always preserve their precision and delicacy is worth mentioning.

The changes in the intensity of the spectral lines as exhibited under different pressures are very interesting If you compare the spectral lines of the halogens with each other, in order to ascertain their homology, and in doing so only employ the spectra of rarefied vapours in Geissler tubes, you meet considerable difficulties, for you can only compare the lines in groups, and these lines present frequently in each of the three elements such differences of intensity that you may be left in doubt as to the existence of a homology of their lines. But the apparent differences arise in reality out of the variation of intensity and the number of the lines with the pressure. By appropriate change in the density of the gas or vapour you can always produce spectra which exhibit the perfect homology of the lines. Thus, in the case of iodine you must employ that tension which iodine-vapour has at 50° or 80° C, while in the case of chlorine and bromine atmospheric pressure is required.

The spectrum of sulphur does not change at all at higher pressure, the lines maintaining their perfect sharpness, while in the red field a continuously illuminated background appears.

Phosphor and arsenic do not give any reaction, and even the continuous spectrum does not appear. With arsenic I observed what I think has hitherto been overlooked, namely, that it gives at a moderate pressure, and without the interposition of a Leyden jar, *a spectrum of the first order*. It is almost continuous, and with increase of pressure of interposition of the jar it gives to the spectrum of lines the spectrum of the second order

Great is the difference between the metalloids of which we have hitherto been speaking and the metals, they show an expansion of their lines into bands, while the continuous light takes a less prominent place In quicksilver the breadth especially of the green and violet lines is conspicuous.

With sodium I have only noticed the great width of the D-lines when they appeared reversed, for I could only examine the light after its passage through a layer of cooler vapour Sodium gives at high pressures a continuously illuminated spectrum near the D-lines, which then appear reversed, at first one or two lines, but soon they widen and merge into each other, and the dark band of absorption gradually covers the whole illuminated part of the field.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

CAMBRIDGE.—Prof Stuart finds the progress of his School of Mechanism and Engineering again compels enlargement. Some pupils are now making small engines, and require more space for erecting them. A room for mechanical drawing is needed, and also an enlarged stove The Museums and Lecture-rooms Syndicate think it best in the present condition of University funds to erect a new temporary building 46 feet long by 21 feet wide, adjacent to the present workshop, and this, with other rooms which can be added, will supply present necessities for about 360*l*.

The balance of 821*l*, being the debt on the last two years of the Museums Maintenance Fund, has been granted as an extra payment from the University Chest, and in future years 3000*l*. will be granted annually for the Museums and Lecture-rooms Maintenance Fund.

Prof. Stuart is to have the services of a Demonstrator of Mechanism and Applied Mechanics

Clare College announces a scholarship of 60*l*. a year in chemistry and chemical physics, botany and geology, to be competed for on March 29 next, without limit of age. Jesus and Magdalene Colleges continue to offer no inducements to natural science.

BY a Royal decree, published last month, a museum will shortly be opened at Palermo on the plan of the one founded in Rome in 1874, with the object of making known the best scho-

lastic materials and best didactic methods adopted with success by the most cultivated and civilised nations. This museum is styled the Pedagogic Museum, and will have its seat in the Royal University. Its aim is to collect, with a view to their recognition and adoption, all objects and publications connected with the mode of instruction in elementary schools, and in general all the new means and appliances which are being successively invented to insure greater efficiency and progress in the arts of instruction and education. All that has till now been collected by the Professor of Pedagogy in the present Museum of Palermo will henceforth belong to the new institution, which is dependent on the Minister of Public Instruction.

SCIENTIFIC SERIALS

THE *Journal of Anatomy and Physiology, Normal and Pathological*, vol. xv. part 1, October, contains.—Dr. C. Creighton, on an infective form of tuberculosis in man, identical with bovine tuberculosis, plates 1 to 6.—Dr. W. Allen, on a third occipital condyle in the human subject, plate 7.—Dr. J. Dreschfeld, some points in the histology of cirrhosis of the liver, plate 8.—Dr. S. Moritz, a contribution to the pathological anatomy of lead paralysis, plate 9.—Dr. G. S. Middleton, vascular lesions in hydrophobia and in other diseases characterised by cerebral excitement, plate 10.—Dr. D. Macphail, an ether percolator, for use in physiological or pathological laboratories, plate 11.—Dr. D. Newman, the comparative value of chloroform and ethidene dichloride as anæsthetic agents.—Dr. R. Pinkerton, observations on the temperature of the healthy human body in various climates.—Dr. George Hoggan and Dr. F. Elizabeth Hoggan, the lymphatics of cartilage and of the perichondrium.—Dr. R. J. Anderson, a palatine branch from the middle meningeal artery.—J. F. Knott, muscular anomalies.

Journal of the Royal Microscopical Society, vol. iii. No. 5, October.—W. H. Gilbert, on the structure and function of the scale leaves of *Lathræa squamaria*.—Dr. H. F. Fripp (the late), on daylight illumination with the plane mirror, an appendix to Part I. of the "Theory of Illuminating Apparatus."—W. Webb, on an improved finder.—W. A. Rogers on Tolles' interior illuminator for opaque objects, with a note by R. B. Tolles.—The record of current researches relating to invertebrata, cryptogamia, microscopy, &c.

THE *American Naturalist*, November.—F. M. Endlich, the Island of Dominica.—J. D. Caton, the Sand-hill Crane.—W. K. Higley, on the microscopical crystals contained in plants (concluded).—J. M. Stillman, on the origin of lac (regards it as a secretion of *Coccus lacca*).—Edward L. Greene, botanising on the Colorado desert.—The Editor's table on the obligations of educational and charitable institutions.

Zeitschrift für wissenschaftliche Zoologie, Band 34, Heft 4, September, contains:—a very elaborate memoir by Dr. Ferdinand Sommer of Greifswald, on the anatomy of the liver-fluke, *Distomum hepaticum*, L., pp. 540-640, with six plates; also by Dr. H. Michels, an account of the nervous system of *Oryctes nasicornis* as it appears in the larval, pupal, and imago conditions of this beetle, pp. 641, 700, with four plates.

Revue Internationale des Sciences biologiques, October 15, contains.—M. Vulpian, a physiological study of poisons, fifth lecture, on curare.—M. Hanstein, protoplasm considered as the basis of animal and vegetable life; introduction.—M. Borodin, on the physiological characteristics of asparagine.—M. L. Portes, on the asparagine of the Amygdaleæ.—G. Thoulet, contributions to the study of the physical and chemical properties of microscopical minerals.

THE *Transactions of the Yorkshire Naturalists' Union*.—Three parts of the above have been issued to the subscribers. These contain reports on the birds of the district, pp. 1-48. On the land and freshwater mollusca, pp. 1-16. On the lepidoptera, pp. 1-80. Botany, pp. 1-51. These reports seem well and exhaustively worked out, and deserve every support from the naturalists of the Yorkshire district and others.

SOCIETIES AND ACADEMIES

LONDON

Mathematical Society, December 9.—Mr. Samuel Roberts, F.R.S., president, in the chair.—Mr. William Ralph Roberts and Mr. Ralph Augustus Roberts were elected Members.—The following communications were made:—Note sur la Dérivation des Déterminants, Prof. Teixeira (Coimbra, Portugal).—Solution of the equation $x^p - 1 = 0$, quinquisection, Prof. Cayley, F.R.S.—A general theorem in kinematics, Prof. Minchin.—On the solution of the inverse logical problem, Mr. W. B. Grove.—Motion of a viscous fluid, Mr. T. Craig.—On the electrical capacity of a conductor bounded by two spherical surfaces cutting at any angle, Mr. W. D. Niven.

Chemical Society, December 2.—Dr. Gilbert, vice-president, in the chair.—The following papers were read:—On the volumes of sodium and bromine at their boiling-points, by W. Ramsay.—On the volume of phosphorus at its boiling-point, by D. O. Masson and W. Ramsay. The authors have determined the atomic volume (the atomic volume = the specific volume × atomic weight) of the following elements in the free state: Bromine 27·135, sulphur 21·60, phosphorus 20·91, sodium 31·00. The authors discuss the formula of oxy-trichloride of phosphorus, and conclude that in that substance phosphorus is a pentad, and that the constitution of that substance is $O{=}P{\equiv}Cl_3$. The atomic volume of phosphorus in this compound is therefore 21·1.—On the specific volume of chloral, by Laura Maude Passavant. Great care was taken in purifying the chloral; the specific volume, determined according to the method of Thorpe, was found to be 107·37.—Note on the formation of carbon tetrabromide in the manufacture of bromine, by J. C. Hamilton. A quantity of a white crystalline substance was obtained as a residue, after distilling a quantity of commercial bromine, it melted at 90°, and contained 97 per cent. of bromine.—Researches on the relation between the molecular structure of carbon compounds and their absorption-spectra, by W. N. Hartley. Part i.—General conclusions as to the nature of actinic absorption exerted by various carbon compounds. Part ii.—Experiments which prove the diactinic character of substances constructed on an open chain of carbon compounds. Part iii.—The actinic absorption exerted by various closed chains of carbon atoms. Part iv.—The absorption spectra of condensed benzen nuclei. Part v.—The cause of absorption-bands in the spectra transmitted by benzene and its derivatives.

Geological Society, December 1.—Robert Etheridge, F.R.S., president, in the chair.—Wm. Heward Bell, Wm. Jackson, Peregrine Propert Lewes, William Libbey, jun., D.Sc., New Jersey, U.S.A.; David Morgan Llewellin, John Marshall, Cyril Parkinson, Cornelius McLeod Percy, Thos. John Robinson, Rev. Alfred Rose, Berby Thompson, and Stuart Crawford Wardell were elected Fellows of the Society.—The following communications were read:—On remains of a small lizard from the Neocomian rocks of the Island of Lesina, Dalmatia, preserved in the Geological Museum of the University of Vienna, by Prof. H. G. Seeley, F.R.S. The author proposed to name this lizard *Adriosaurus suessii*.—On the beds at Headon Hill and Colwell Bay in the Isle of Wight, by Messrs. H. Keeping and E. B. Tawney, M.A. The authors criticised the views put forward by Prof. Judd in his paper published in the *Q. J. G. S.* xxxvi. p. 13, and supported those established by the late E. Forbes and the publications of the Geological Survey. The authors reject Prof. Judd's term Brockenhurst series, and revert to the classification and nomenclature of the Geological Survey.

Zoological Society, November 30.—Dr. Edward Hamilton, vice-president, in the chair.—Mr. Alfred E. Craven, F.Z.S., read a paper on a collection of land and fresh-water shells from the Transvaal and Orange Free State in South Africa, with descriptions of nine new species.—A second paper by Mr. Alfred E. Craven contained the descriptions of three new species of land shells from Cape Colony and Natal.—Surgeon Francis Day, F.Z.S., communicated a paper by Prof. A. A. W. Hubrecht, which gave an account of a collection of reptiles and amphibians made by Dr. C. Duke in Beloochistan.—A communication was read from Mr. J. H. Gurney, F.Z.S., containing a description of the immature plumage of *Dryotriorchis spectabilis* (Schleg.), a very scarce raptorial bird from Gaboon, now living in the Society's collection.—A communication was read from Mr. Roland Trimen, F.Z.S., on an undescribed *Laniarius* obtained by Dr. B. F. Bradshaw on the Upper Limpopo, or Crocodile River, in Southern Africa, which he proposed to name *Laniarius atrocroceus*.—A communication was read from Dr. G. Hartlaub, F.M.Z.S., containing descriptions of five new birds that had been collected by Dr. Emin Bey in Central Africa. These were proposed to be called *Tricholais flavotorquata*, *Cisticola hypoxantha*, *Eminia lepida*, *Drymocichla incana*, and *Muscicapa*

infulata.—Mr. W. A. Forbes, F Z S., read a paper on the external characters and anatomy of the Red Ouakari Monkey (*Brachyurus rubicundus*), describing more particularly the liver and brain, and made remarks on the other species of that genus and their distribution.

Anthropological Institute, November 23 —Allen Thomson, M D., F R S., vice-president, in the chair —The election of W R. Huggard was announced —A paper by Dr. Paul Topinard, entitled observations upon the methods and processes of anthropometry, was read Anthropometry means the measurement of the entire human body with the view to determine the respective proportion of its parts —1. At different ages, in order to learn the law of relative growth of the parts 2 In the races, so as to distinguish them and establish their relations to each other 3 In all the conditions of surrounding circumstances, in order to find out their influence upon the variations ascertained The number of skeletons at disposal for this purpose being small, all our efforts should tend to make perfect the methods of operating upon the living, and to simplify them, so as to render them accessible to all, to travellers, officers of the navy, recruiting agents, schoolmasters, &c., hence the number of measurements should be reduced to those strictly necessary, and only those insisted on which are really useful and lead to the knowledge of one of the natural morphological divisions of the body Heights above the ground, breadths, some circumferences, and perhaps the facial angle—to these we ought to limit our demands. The dimensions to be obtained directly, or by the method of subtraction, relate to —1 The trunk 2. The head and the neck taken separately. 3 The lower limb as a whole. 4. The upper limb as a whole 5 Each of the segments of the limbs, the hand, the forearm, and the arm in the one case, the foot, the leg, and the thigh in the other 6 The intrinsic proportions of the head, of the trunk, of the foot, and of the hand. Three fundamental principles to be observed are, determination and marking the reference points *slowly*, taking the measurements quickly, and the possession of good instruments The choice of reference points is a matter of great importance, and the author explained his views upon this subject —A paper by Mr. C. Staniland Wake on the origin of the Malagasy was read.

Physical Society, November 27 —Prof. W G. Adams in the chair —New Member, H C Jones, F.C.S —Prof Graham Bell exhibited his photophone, and explained the apparatus employed by Mr Sumner Tainter and himself for transmitting sound by a beam of light. The form in use consists of a metal plate or mirror vibrated by the sound and reflecting a beam of light to a distance, where it is focussed on a selenium cell in circuit with a telephone and battery. The light undulates in sympathy with the vibrations of sound, and alters the resistance of the selenium in accordance with the vibrations, thereby reproducing the sound in the telephone The electric light used was too unsteady to give articulate speech, but by means of a rotating disk perforated round its rim with holes the light could be occulted in such a manner as to give an audible note in the telephone Different varieties of receivers were described, some of which have not yet been tried One of these consisted in varying the rotation of the plane of polarisation of the polarised beam. A plan for transmitting the beam consists in making the vibrating plate vary the supply of gas to a jet or manometric flame The farthest distance speech has been heard by a photophone is 800 feet, but theoretically it should operate better the greater the distance between the mirror and selenium. On interposing a sheet of hard rubber in the ray, the invisible rays passing through it conveyed the sounds in a lower degree, and sounds can be heard by replacing the selenium receiver by disks of different materials, such as hard rubber, metal, &c, and simply listening at them. All substances appear to possess the power of becoming sonorous under the influence of varying light. Hard rubber, antimony, zinc, give the best effects, paper, glass, carbon, the worst. Even tobacco-smoke in a glass test tube held in the beam emitted a note, as also did crystals of sulphate of copper. When hard rubber was simply made into the form of an ear-tube and held in the beam, the audible effect was also produced, and in fact when the beam was focussed in the ear itself, without any other appliance whatever, a distinct sound could be perceived.—Prof. Adams thanked Prof Bell in the name of the Society, and called on Mr. Shelford Bidwell, who exhibited a lecture photophone, in which the reflector for receiving the light was discarded and the beam focussed on the selenium by a lens. The two lenses used cost only 25*s.*, and the beam was sent fourteen feet. The selenium cell was made by spreading melted selenium over sheets of mica, and then crystallising it by heat. For mica Prof. Bell recommended microscopic glass. The resistance of the cell was 14,000 ohms in the dark, and 6500 in the light. Speech was distinctly transmitted by this apparatus. Mr. J. Spiller thought that since selenium probably alloyed with brass and the baser metals, it would be better to use gold and silver for the cells, but Prof Bell said that he preferred brass, since (perhaps for the reason that Mr. Spiller gave) it yielded the best results.—Dr. J H. Gladstone read a paper on the specific refraction and dispersion of isomeric bodies—an extension of his paper of last June. He concluded that the dispersion of a body containing carbon of the higher refraction is very much greater than that of a body containing carbon of the normal refraction 5, and that isomeric bodies which coincide in specific refraction coincide also in specific dispersion

Entomological Society, December 1.—Sir John Lubbock, F.R.S, president, in the chair —Mr. Pascoe exhibited a large series of *Arctcus histrio* from Peru, to show the extreme variability of the elytral markings in this species.—Mr. Billups exhibited four species of *Pezomachus* new to Britain, viz, *P Mulleri*, *P juvenilis*, *P intermedius*, *P incertus*, and also exhibited twenty species of Coleoptera found in a small parcel of corn refuse The president exhibited two specimens in alcohol of a species of *Phasmidæ* forwarded by a correspondent in St. Vincent. Mr Cansdale exhibited a specimen of *Tischeria ganacella*, a species of *Tinæina*, new to Britain, he also exhibited a remarkable variety of *Cidaria russata*.—Mr J. Scott communicated a paper on a collection of Hemiptera from Japan. —Mr. C O. Waterhouse read a paper entitled description of a new species of the anomalous genus *Polyctenes*, and exhibited a diagram illustrating the structure of this insect

Royal Asiatic Society, November 15.—Sir H C. Rawlinson, K C B, F R.S, president, in the chair —Sir W R. Robinson, K C S I., S S Thorburn, Capt R Gill, R E., and the Rev Marsham Argles, M A., were elected Resident Members, and the Bishop of Lahore, Lieut. H E. McCallum, R.E, S. W. Bushell, M.D, and Abd-er-rahman Moulvie Syed, barrister-at-law, Non-resident Members.—Prof Monier Williams, C I.E, read a paper on Indian theistic reformers, in which, after showing that Monotheism was not of recent growth in India, he traced the development of the modern Theistic churches there, from Rammohun Roy, who formulated a system which may be described as Unitarianism based on Brāhmanism, through his successor, Debendra Nāth, who improved on Rammohun Roy's work by founding the Adi Brāhma Samāj, to Keshub Chundar Sen, who threw off altogether both Brāhmanism and caste, and founded his new progressive Brāhma Samāj in 1866. In his present eclectic form of Theism, composed of Hinduism, Mahammedanism, and Christianity, he teaches the worship of God under the character of a Supreme Mother Some of his followers, offended with him, chiefly for marrying his daughter before she was fourteen to the Mahārāja of Kuch-Behar, have recently set up a new Theistic Church called the Sudhārana Brāhma Samāj, or Catholic Church of God. There are now more than 120 Theistic churches in different parts of India

Royal Microscopical Society, December 8 —Mr. J. Glaisher, F R S, in the chair —Eight new Fellows were elected —Mr Wallis exhibited a new rotating substage, Mr. Mayall his form of spiral diaphragm, and Tolles' mechanical stage of extra thinness, and Mr. Crisp Crouch's histological microscope, Parkes's demonstrating microscope, Holmes's compressorium, and Atwood's rubber-cell —A paper by Dr. Hudson was read, on a new *Œcistes* (*Janus*), and a new *Floscularia* (*trifolium*), found by Mr Hood of Dundee in Loch Lundie. The trochal disk of the former formed a link between that of *Melicerta* and *Œcistes*. The latter was remarkable in having only three lobes and being much larger than any Floscularia hitherto known.—Mr. Stewart explained some peculiar structural features of the Echinometridæ, illustrated by specimens and drawings

Institution of Civil Engineers, November 9.—Mr. W. H. Barlow, F.R S., president, in the chair.—The paper read was on machinery for steel-making by the Bessemer and the Siemens' processes, by Mr Benjamin Walker, M. Inst. C.E.

December 7 —Mr. W. H. Barlow, F.R.S., president, in the chair.—The paper read was on the different modes of erecting iron bridges, by Mr. Theophilus Seyrig, M. Inst. C.E., of Paris.

Royal Society of Literature, November 24.—Mr. Charles Clark, vice-president, in the chair.—Sir Hardinge Stanley Giffard, Mr. Ramchundra Ghose, Mr. Henry Allpass, Mr. Robert White Boyle, Capt. W. Deane Seymour, Dr Altschul, were elected members.—Mr. F. G. Fleay read a paper entitled the living key to English spelling reform now found in history and etymology. The object of Mr. Fleay's paper was to show that the objections to spelling reform are principally founded on an exaggerated estimate of the amount of change required. This exaggeration has been caused by the revolutionary proposals of the leading reformers, who neglected the history of our language and the etymological basis of its orthography in favour of philosophical completeness. Mr. Fleay, on the other hand, proposed a scheme which was developed in two forms, one perfectly phonetic for educational purposes, the other differing from this only in dropping the use of the accents and the one new type required in the former. He showed that even in the vowel sounds not one-tenth would need alteration, while in the case of the consonants the alteration required would of course be much less.

Photographic Society, November 9.—J. Glaisher, F.R.S., president, in the chair.—Major Waterhouse, Bengal Staff Corps, read a paper "On a new method of obtaining 'grain' in photo-engraving." The method alluded to was to squeeze into the gelatine relief, while wet, sand- or glass-paper, previously waxed to ensure removal. The contraction of the paper while drying would force the granular substance into the relief more strongly in the shadows than in the lights, and thus a discriminating grain would be produced.—Capt. Abney, R.E., F.R.S., read a paper, "Notes on the gelatine process." The point insisted upon was that gelatine emulsions if kept some time before being poured upon the plates, extra sensitiveness would be the result; another matter was, that "frilling" could be prevented by the same long keeping of the emulsion; also that with emulsions where silver iodide is used, a few drops of hyposulphite of soda would bring out more detail in the image.

CAMBRIDGE

Philosophical Society, November 8.—Prof. Newton, president, in the chair.—The following communications were made to the Society:—On a new arrangement for sensitive flames, by Lord Rayleigh. A jet of coal gas from a pin hole burner rises vertically in the interior of a cavity from which the air is excluded. It then passes into a brass tube a few inches long, and on reaching the top burns in the open. The front wall of the cavity is formed of a flexible membrane of tissue paper, through which external sounds can reach the burner. The principle is the same as that of Barry's flame described by Tyndall. In both cases the *unignited* part of the jet is the sensitive agent, and the flame is only an indicator. Barry's flame may be made very sensitive to sound, but it is open to the objection of liability to disturbance by the slightest draught. A few years since Mr. Ridout proposed to inclose the jet in a tube air-tight at the bottom, and to ignite it only on arrival at the top of this tube. In this case however external vibrations have very imperfect access to the sensitive part of the jet, and when they reach it they are of the wrong quality, having but little motion transverse to the direction of the jet. The arrangement now exhibited combines very satisfactorily sensitiveness to sound and insensitiveness to wind, and it requires no higher pressure than that of ordinary gas-pipes. If the extreme of sensitiveness be aimed at, the gas pressure must be adjusted until the jet is on the point of flaring without sound. The apparatus exhibited was made in Prof. Stuart's workshop. An adjustment for directing the jet exactly up the middle of the brass tube is found necessary, and some advantage is gained by contracting the tube somewhat at the place of ignition.—Lord Rayleigh, on an effect of vibrations upon a suspended disk. In the British Association experiment for determining the unit of electrical resistance, a magnet and mirror are inclosed in a wooden box, attached to the lower end of a tube through which the silk suspension fibre passes. Under these circumstances it is found that the slightest tap with the finger-nail upon the box deflects the mirror to an extraordinary degree. The disturbance appears to be due to aerial vibrations within the box, acting upon the mirror. We know that a flat body, like a mirror, tends to set itself across the direction of any steady current of the fluid in which it is immersed, and we may fairly suppose that an effect of the same character will follow from an alternating current. At the moment of the tap upon the box the air inside is made to move past the mirror, and probably executes several vibrations. While these vibrations last the mirror is subject to a twisting force tending to set it at right angles to the direction of the vibration. The whole action being over in a time very small compared with that of the free vibrations of the magnet and mirror, the observed effect is as if an impulse had been given to the suspended parts. The experiment shown is intended to illustrate this effect. A small disk of paper, about the size of a sixpence, is hung by a fine silk fibre across the mouth of a resonator of pitch 128. When a sound of this pitch is excited, there is a powerful rush of air in and out of the resonator, and the disk sets itself promptly across the passage. A fork of pitch 128 may be held near the resonator, but it is better to use a second resonator at a little distance, in order to avoid any possible disturbance due to the neighbourhood of the vibrating prongs.

PARIS

Academy of Sciences, November 29.—M. Edm. Becquerel in the chair.—MM. E. and J. Brongniart presented a work on the silicified fossil seeds of strata of Autun and Saint Etienne, to which their father had devoted the closing years of his life. These researches led, among other things, to observation of a pollinic chamber in some living as well as in fossil species of seeds.—Note relating to a memoir on vision of material colours in rotation, and velocities estimated in figures by means of the turning-plate apparatus of General Morin, for observation of the laws of motion, by M. Chevreul.—On the spontaneous oxidation of mercury and of metals, by M. Berthelot. He concludes from experiment that mercury, like iron, zinc, cadmium, lead, copper, and tin, undergoes, in contact with air, a superficial oxidation, very slight, indeed, and limited by the difficulty of renewal of the surfaces and the absence of contact resulting from commenced oxidation. This agrees with thermic data. The oxidation of mercury liberates per equivalent of fixed oxygen + 21.1 cal (iron 31.9, tin 34.9, &c.). Spontaneous oxidation is not appreciable in metals whose heat of oxidation is very small, *e.g.* silver (+ 3.5 cal.). The greater rapidity of the reaction where an agent intervenes, which is capable of combining (with liberation of heat) with the substance produced, *e.g.* an acid, is shown to be in agreement with thermic theory.—On the propagation of light, by M. Gouy. He examines the case in which the rays have a constant direction, but vary in intensity, the source undergoing variations or being eclipsed by a moving screen. There is not, for a given homogeneous source, a determinate velocity of light, independent of the manner in which the amplitude is varied. But in every realisable experiment this variation is effected in a gradual and very slow manner relatively to the vibratory period; here the formulæ are simplified and the amplitude is transported as in a non-dispersive medium (with a velocity which is indicated by formula). The index of refraction is connected with the velocity of light by a relation easy to establish.—On linear differential equations with periodic coefficients, by M. Floquet.—On a new electric property of selenium, and on the existence of tribolectric currents properly so-called, by M. Blondlot. To one pole of a capillary electrometer a piece of annealed selenium is attached with a platinum wire; to the other pole a platinum plate. If the selenium be brought (with an insulating handle) into contact with the platinum the electrometer remains at zero; but on rubbing the selenium against the platinum a strong deflection occurs (often equal to that produced by a sulphate of copper element). The thermo electric current got by heating the selenium-platinum contact has an opposite direction to that of the current in question (which is from the unrubbed to the rubbed part of the selenium); thus the effect cannot be attributed to heat. On ceasing to rub, the deflection persists; the selenium, which let pass the high-tension electricity due to friction, opposing too great resistance for the weak polarisation of the mercury. Shock and even pressure produce the same effect as friction, though in less degree.—Action of phosphorus on hydriodic and hydrobromic acids, by M. Damoiseau.—On Waldivine, by M. Tanret. This is the active principle of the fruit of *Simaba waldivia*, which grows in Columbia. The composition of the crystals is represented by $C_{36}H_{24}O_{20}5HO$. The physical and chemical properties are described.—Direct analysis of peat; its chemical constitution, by M. Guignet. This relates to peat of very modern formation in the Somme Valley, formed under water in presence of carbonate of lime. Treated with water it yields *crenic* and *apocrenic* acid, also a little sulphate of lime. Alcohol at 90° produces a clear green solution, from which vegetable wax is got in abundance (the green matter has all the characters of chlorophyll). The

presence of *glucosides* can also be proved. Part at least of the total nitrogen of the peat (amounting to 3 per cent.) enters into the composition of the brown matters.—On the geology of the Northern Sahara, by M. Roche. *Inter alia*, he found in the middle of the Great Erg, south of Ouargla, a broad plane region about 250 km. long, covered only with isolated parallel dunes lying along the magnetic meridian; an important feature for the Trans-Saharan railway. All the strata of the Northern Sahara are nearly horizontal.—On some phenomena of optics and vision, by M. Trève. Looking at a lamp-flame through a fine slit in a disk, the brightness and the diffraction effects vary much, according as the slit is vertical or horizontal.—M. Maumené in a note attributes the difference of experimenters as to absorption of oxygen by mercury to more or less silver contained by the mercury.—M. Dubalen announced the discovery of a prehistoric grotto in the Department of Landes.

December 6.—M. Edm. Becquerel in the chair.—The following papers were read:—On the development of any function of the radius-vector in elliptic motion, by M. Tisserand.—Spectral reaction of chlorine and bromine, by M. Lecoq de Boisbaudran. For detecting minute traces he fuses on the hooked lower end of a platinum wire some pure carbonate of baryta; places in the bend a drop of the liquid to be examined; then evaporates, heating momentarily to a nascent red (with partial fusion); another platinum wire is then brought near the bend from below, and the induction spark gives a spectrum with lines of $BaCl_2$ or $BaBr_2$. The $\frac{1}{400}$ mgr. of chlorine or bromine may be thus detected.—M. Brioschi was elected correspondent in geometry in room of the late M. Borchardt.—On the action of water in applications of sulphide of carbon to phylloxerised vines, by M. Catta. He shows the injurious action of excessive humidity. The sulphide need not be in the liquid state if the ground be quite saturated with water.—On the swarming of phylloxera in 1880, by M. de Lafitte. This has been small, almost nil in some parts. The phenomenon is probably periodic, with a two years' period.—On mildew, *Peronospora* of vines (*Peronospora viticola*, Berk. and Curt.), by M. Cornu. This mildew will soon (perhaps next year) have spread over all France; and it is still almost unknown in regions where it prevails. The grape is not directly attacked, but the plant is injured, often disastrously.—New process for destruction of kermes of fig (*Ceroplastes rusci*, Lin.), by M. Gennadius. The insects may be got rid of by making a number of incisions on the trunk and branches, causing the plant to lose a large quantity of latex.—Observations of comet *d* 1880 (Hartwig) at Paris Observatory, by M. Bigourdan.—On the same comet and on Swift's comet (*e* 1880), by MM. Schulhof and Bossert. He obtains for the former a revolution of 1280 years (uncertain); for the latter, 5½ years.—On the method employed by Aubuisson in 1810 for measurement of geodetic bases, by M. Laussedat. This is, in substance, the same as the method now recommended exclusively by the International Geodetic Commission.—On the calculation of heights by means of barometric observations, by M. Angot. He cites some figures as showing the precision of his new method.—On the distribution of temperatures in the lower strata of the atmosphere, by M. André. From observations on the north and south slopes of Mont Verdun (625 m. in height) he infers that in the same vertical the distribution of temperature up to a certain height is absolutely indeterminate, thin hot- and cold-air currents being superposed on one another. The mode of superposition is in direct relation to the centres of high and low pressures.—On radiophony, by M. Mercadier. This name he gives to the phenomenon lately discovered by Prof. Bell. He shows reason for thinking it is not an effect of the mass of the receiving plate vibrating as a whole. Also the nature of the molecules of the receiver and their mode of aggregation do not seem to have a predominant *rôle* in the nature of the sounds produced. These sounds (he thinks) are due principally to direct action of calorific radiations on the surface of the receiver. (He got the maximum effect with invisible vibrations in the red and infra red.)—On the existence of perboric combinations, by M. Etard. Boric acid in presence of oxygenated water acts like a different acid, though of little stability: perboric acid.—On cobaltamines, by M. Porumbaru.—Researches on the comparative anatomy of the nervous system in the different orders of the class of insects, by M. Brandt. He gives the results of his own observations on Coleoptera, Lepidoptera, Diptera, and Hemiptera.—On a new form of vesicular worm, with exogenous gemmation, by M. Villot. This is named *Urocystis prolifer*, is a parasite of *Glomeris limbatus*, and has the peculiarity of living in the same host in different degrees of development; in the vesicular state proper, in the visceral cavity; in the state of scolex, encysted in adipose tissue. Buds are successively formed (containing a scolex) and detached.—Habits of a fish of the family of Silures, the *Callichthys facratus*, Cuvier, by M. Carbonnier. Its mode of reproduction is peculiar.—New researches on saxifrages; applications of their products to the arts and to therapeutics; experiments on their cultivation, by MM. Garreau and Machelart. Attention is called to a new substance, *bergenin*, obtained from the stocks; in the free and crystalline state it is represented by $C_8H_4O_4$. It is a strong neuro-sthenic tonic (between quinine and salicine). The tannin and fecula also obtainable, further recommend the cultivation of saxifrages.—On a process of meat-preservation by means of dextrine, by M. Senre. Meat dried and preserved with dextrine has remained unaltered twenty months, exposed to air.—The meteors of November 14, 1880, observed at Moncalieri (Italy), by M. Denza. Four observers counted thirty-seven in three-quarters of an hour. More than a third belonged to the stream of the Leonides, and they were the most beautiful.

VIENNA

Imperial Academy of Sciences, December 9.—Dr. Fitzinger in the chair.—Researches on Liverworts; 6. Marchantieæ, by Herr Leitgeb.—On the watercourses of middle Europe, and the importance of regulation of the Danube, with special reference to the stretch between Theben and Gonyo (Hungary), by Herr Lanfianconi.—On the formation of germinal layers in the hen's egg, by Herr Koller.—On combinations of chloride of calcium with fatty acids, by Herr Lieber.

Imperial Institute of Geology, December 7.—Geological map of the environs of Gratz, by Herr Hornes.—On a new mineral, *schneebergite*, by Herr Brezina.—Tectonics of the dioritic eruptive rocks of Klausen (Tyrol), by Herr Teller.—Geological map of Gorlice, by Herr Trajnocha.—On Predazzo, &c., by Herr Reyer.

THE FOGS OF LONDON

LAST week Mr. Scott Moncrieff described in our columns a method of all but entirely eliminating smoke from the atmosphere of London, and thus abolishing that most venerable of our institutions—Fog. And in a recent number Dr. Siemens showed how our existing grates could be made to give out a maximum of heat at a minimum of expense and an entire absence of smoke. It may therefore be of some interest to inquire briefly into the latest theories as to the causes and consequences of this hideous incubus which renders residence in London a terror to so many.

Fogs are supposed to form a constituent part of the climatology of the British Islands from which there is no escape, and in certain strictly local climatologies, such as that of London, where the aggregation of human beings is altogether unprecedented, they now and again acquire an extraordinary intensity and persistency, and are attended with consequences so disastrous and fatal as to press urgently on Parliament the necessity of legislation towards the mitigation of the evil.

In illustration of this, reference may be made to the influence on the mortality of London exercised by the fog which prevailed there from November, 1879, to February, 1880, which was so remarkable both for its denseness and protractedness, as to constitute it one of the most memorable fogs on record The question has been investigated by Dr. Arthur Mitchell, and the results recently published in the *Journal* of the Scottish Meteorological Society

The increase in the death-rate was truly enormous, as these figures, giving the whole mortality for each of the seven weeks ending February 21, show—1754, 1730, 1900, 2200, 3376, 2495, and 2016; in other words, several thousand persons fell victims to the disastrous fatality of this great fog. An examination of the figures in the Registrar-General's Reports shows that no approach to so large an increase in the death-rate showed itself in any of the other British large towns, and in none of these did fog of a noteworthy character occur Of all diseases, asthma was most directly influenced in its fatality by the fog; for as the density of the fog increased so did the deaths from asthma, and as the fog abated, relief came at once to the asthmatic, and the death-rate instantly fell Thus the mortality rose to 220 per cent above the average during the week of densest fog, but as the fog gave way the mortality fell to 40 per cent. below the average Bronchitis, pneumonia, pleurisy, and other lung diseases appeared also with an enormously increased fatality, the mortality from bronchitis rising during the week when the fog was at its worst to 331 per cent. above its average In the case of these diseases however the relief did not come instantaneously with the cessation of the fog, but injuries of a more permanent nature appear to have been sustained which kept the death-rate at a high figure for some time after the fog had finally disappeared. Whooping-cough exhibited these characteristics in even a still more pronounced manner. The pernicious effects of the fog lingered still longer in the system, so that while the death-rate rose during the worst week of the fog to 182 per cent. above the average, four weeks thereafter it had fallen no lower than 74 per cent above the normal mortality of whooping-cough. It is singular, and particularly to the medical profession profoundly interesting, that deaths from croup, diphtheria, and rheumatism did not show any distinct relation to the fog As regards the other diseases, the deaths from which are registered, they equally did not appear to show any steady connection with the fog's varying denseness and persistency.

This pernicious and deadly character of fog on persons suffering from these diseases is not due to fog as such, but to the noxious qualities imparted to it by our large towns. Dr. Angus Smith has shown that the air of Manchester during an extremely dense fog contained 20 85 per cent of oxygen, or one-tenth per cent less than the normal quantity. The pernicious character of fog however is to be traced not so much to this slight diminution of atmospheric oxygen as to the presence of positively deleterious substances.

The smoke which issues from our dwelling-houses contains, in addition to solid soot, also gaseous carbonic acid, sulphurous acid, carbon monoxide, sulphide of ammonia, and sometimes minute traces of arsenic Moreover the soot does not consist of particles of carbon only, but carbon saturated with tarry matters, sulphur and ammonia compounds, &c. Smoke from manufactories is usually more completely burned than that from dwelling-houses, and is therefore less deleterious In many cases however manufactories pour out into the air their own specific hurtful gases. Of these gases the more pernicious are mineral acids, especially sulphuric and hydrochloric acids, sulphuretted hydrogen, sulphur dioxide, and oxide of arsenic. Gases rising from decaying animal and vegetable matter in waste heaps and in faulty sewers also lend their aid in the contamination of the atmosphere of towns In the neighbourhood of various manufactories solid impurities crowd the air, resulting in a denseness of fog in these restricted localities with an accompanying suffering and fatality elsewhere unknown

In February last we drew attention (NATURE, vol xxi. p. 355) to the question of fogs and the general atmospheric conditions under which they are generated, when the importance in discussing the question of fogs of a careful study of the anticyclone and its accompaniments was adverted to Indeed it is in the highest degree probable that all our memorable great fogs are intimately connected with the anticyclone, being found towards their outskirts or rather in the debatable region between the cyclone and the anticyclone They arise from the diffusion of the vapour brought up by the cyclone outwards and through the colder and drier air of those parts of the anticyclone contiguous to it, where it is condensed into immense breadths of fog stretching several hundred miles in length.

The two features of the anticyclone to which more special attention is directed are these, (1) the calmness or comparative calmness of the air, and (2) the *slow downward general movement of the atmosphere over the region covered by the anticyclone*, and a general outward movement in all directions towards surrounding regions as we near its outskirts

Consider now this feature of the anticyclone in its

relation to the vast quantities of deleterious matters which are vomited into the atmosphere from the chimneys of London. The horizontal movement of the air is at a minimum, and thus altogether insufficient to sweep these noxious matters out into the surrounding country The impurities therefore ascend into the air over London, and when no longer buoyed up by the warmer air with which they began the ascent, they fall under the influence of the general downward movement of the atmosphere, and this downward movement is accelerated by the solid impurities becoming saturated with condensed aqueous vapour, coal-oil, and tarry substances. Hence the specially noxious fogs of large towns settle near the surface, are no more than a few fathoms in depth, and are at the maximum where chimneys are planted thickest, the situation low-lying and confined, and where consequently the horizontal circulation of the air is absolutely arrested

If we would then overcome, or in any way mitigate, the terribly fatal effects of our city fogs, it can be done in no other way than by Parliament interposing with a legislation which will not only effectually stop the emanation of deleterious exhalations from manufactories, but also compel the combustion of the smoke arising from ordinary fires in dwelling-houses As regards the latter, where the real difficulty in legislating lies, it may be stated that we already have appliances for thoroughly burning coal, the use of which would be attended with an immense saving of money to the community, as well as the prevention of the painful recurrence of periods of such widespread sickness and mortality as London passed through in the beginning of the present year But it is of little use in science showing how this terrible evil may be cured if the authorities make no attempt to put her hardly obtained results into practice, it would cost little to give both Dr. Siemens's and Mr Moncrieff's methods a fair trial on something more than a miniature scale But what are some of the obstacles to such a practical course may be seen from our correspondence columns to-day.

WHAT IS CIVILISATION?

The Past in the Present. What is Civilisation? By Arthur Mitchell, M D, LL D 8vo pp xvi and 354. (Edinburgh David Douglas, 1880)

THIS interesting volume, as may be inferred from the title, embraces two cognate but at the same time somewhat diverse subjects—the one the survival, or possibly the reintroduction, of objects and customs, which are usually regarded as primitive, among the civilised nations of the present day, the other the nature and origin of civilisation

As Rhind Lecturer on Archæology Dr Arthur Mitchell selected these two subjects as the topics on which to enlarge, and devoted six of his lectures to the first and four to the second, and these lectures, illustrated by nearly 150 excellent illustrations, form the body of his book, to which is added a long appendix and a detailed analytical table of contents.

The facts brought forward in the first portion of the work, though for the greater part by no means new to most archæologists, are of considerable general interest, and will appear sufficiently striking to the ordinary reader. The peregrinations of the author in the remoter districts of Scotland and the neighbouring groups of islands have brought him in frequent contact with those among whom ancient customs are most likely to have survived, whose domestic appliances are often of the same simple character as were those of their ancestors generations and generations ago, and whose ordinary life has also been but little affected by the advance in material civilisation of their fellow-countrymen. To these objects and customs so persistently surviving from the Past into the Present the term "neo-archaic" has been applied by Prof Rolleston, and it is precisely these objects that a practised archæologist declines to regard as ancient, unless the circumstances of their finding justify him in so doing Foremost among them is placed the whorl and spindle, an appliance for spinning still in use in parts of Scotland, as it is throughout the whole of the continent of Europe, and which indeed is never likely to be entirely supplanted by the spinning-wheel or other machinery, so long as the use of the spindle can be combined with an out-of-doors occupation, such as tending sheep or cows All will agree with Dr Mitchell that the mental power of those Scotch women who still use the spindle and whorl need not be a whit inferior to that of those who do not use it, and some will go farther, and place the shepherdess who spins in a higher rank than the one whose hands are idle all the day-long That a spindle should be made of a form to do without a whorl, or that a potato should be substituted for the latter, are regarded by the author as signs of the art of spinning by hand having reached a state of degradation, but if producing the greatest effect with the least possible trouble is any sign of progress, such an opinion is questionable.

In all such cases the external circumstances of a family or group of families must be taken into consideration, and if it be cheaper or more easy to employ articles of the simplest and rudest character than to purchase, it may be from a distance, the appliances of modern art, the simple methods and appliances will survive. Netting and knitting by hand will thrive by the side of netting and knitting by machinery, as the long hours of a winter's evening, which might otherwise be wasted, can thus be utilised at practically no cost; and it seems more remarkable that the simple form of narrow loom for webbing, of which Dr Mitchell gives a figure, should have become almost extinct, than that it should have survived.

A flint for striking a light may be cheaper and in some respects more convenient than lucifers, and the "knockin'-stane" and mallet are not less effective for their purpose than the most expensive pestle and mortar. The earthenware "craggans" are as cheap and as well adapted for the ends they serve as pots thrown on the wheel, and in countries where carriage is difficult or extensive water power scarce, the quern or hand-mill and the little Norse-mill may still hold their own; as they did in St Alban's in the fourteenth century, when they competed with the high charges for multure at the Abbey mills. The survival of the black houses and beehive houses in the Hebrides may also probably be reduced to a question of cost. Perforated or grooved stones are cheaper than plummets of lead as sinkers for nets and lines; and for working in water a pivot and socket of

stone is probably both cheaper and more durable than one of metal The existence of sockets and other working parts formed of stone in our best clocks and watches can hardly be regarded as an instance of low civilisation, or of those who use them being in the Stone Age

In all these remarks Dr Mitchell will perhaps agree, and if the object of his lectures were merely to inculcate caution in accepting such objects as those he describes as belonging of necessity to any remote antiquity or to an absolutely rude and barbarous people, most archæologists would fully endorse his views But there is throughout these lectures a more or less evident intention that they should apply not to any minor questions of archæological classification, but to the far greater question of the progress of the human race. Though accepting the ordinary division of antiquities into those of the Stone Age, of the Bronze Age, and of the Iron Age, he does not regard the use of stone, bronze, or iron as in any way indicative of the culture and capacity of those who used them No doubt many of those who use iron and steel are mentally barbarians, and certainly the instances the author brings forward of the superstitious beliefs still prevalent in Scotland show how deeply rooted are such relics of early beliefs, and how little material civilisation has done to elevate the mental culture of the mass of the population. The distinction Dr Mitchell draws between culture and civilisation is one which is well illustrated by the continued existence of such low forms of belief, and all his readers will agree with him that it is an error to suppose that in this or any other civilised country the mass of the people can be spoken of as highly cultured. Civilisation he defines to be nothing more than a complicated outcome of a war waged with Nature by man in society to prevent her from putting into execution in his case her law of Natural Selection

Such a view of mankind being to a certain extent exempt from the operation of that law has already been held by many, but even if accepted does not appear to contradict the opinion that the human race may have been evolved from some lower form of mammalian life For on such an assumption it is, as Dr Mitchell insists, impossible that man in isolation could become civilised, while, on the other hand, it is evident that until he had become sufficiently intelligent or cultured to enter into association with his fellow men, he would remain subject to the law of Natural Selection in the same manner as any members of the brute creation. Nor even when the stage of association was reached can we expect that there should have been at once any great development of mental power, for there is a long interval between the banding together of a certain number of human units, and any one of them being in that position of ease and leisure which is so necessary for mental culture.

It is perfectly true that so far as osteological evidence is concerned there appears to be no tangible difference between the earliest known remains of man and the human frame of the present day. But it is by no means certain that all the skulls which have been attributed to the Quaternary Period actually belong to so remote an antiquity; and it is worth while to remember that among the coolies of China and some of the Pelew islanders, while the weight of the brain is singularly great, it is balanced by a marked deficiency in the number and depth of the secondary convolutions and by a want of depth in the grey matter

Dr Mitchell's view, though we believe nowhere clearly expressed, appears to be that during the whole period of the existence of the human race there was in some part of the world a state of civilisation in existence, which would imply that those among whom it prevailed were possessed of the same average mental capacity as any people or nation of the present day "May it not happen," he says, "that dealing with the human race as a whole, there never has been a time in its history when there did not occur among men states both of high and of low civilisation? Is it not also possible that there may have never existed a time in the history of mankind as a whole when there were not among those composing it persons potentially as good—persons exhibiting as high a capacity—as any among those who now go to make up mankind?" Were the history of our race confined to the last five or six thousand years it might be hard to answer these questions otherwise than in the affirmative, but who that appreciates the vast antiquity of man as established by recent geological discoveries will admit that such a term forms more than a small fractional portion of the period of man's existence upon the earth, or that there is any parity of reasoning between the circumstances of the beginning of the human period and of the comparatively recent times of Egyptian or Assyrian civilisation?

Granted even that the potential mental capacity existed, of what use could it have been to those who were daily on the brink of starvation, who were unacquainted with writing, and with metal, and had not even succeeded in domesticating any of those animals which now seem almost necessary for human existence?

This however is not the place to enter into a long discussion as to the origin and progress of civilisation. Those, and they are many, who are interested in this subject will do well to read Dr Mitchell's book, and even should they not agree with all his conclusions, will feel that his cause has not suffered from the treatment it has received at his hands.

They will also find in his Appendix much valuable matter extracted from the writings of Mr. Alfred R Wallace, Mr. Herbert Spencer, and Mr Bancroft To the antiquary pure and simple the illustrations of the "neo-archaic" objects still in use in Scotland will be attractive and valuable, and should some stray politician take up the volume some of the reflections on the dangers to civilisation which may arise from over-legislation, as set forth in the last of the lectures, may profitably be studied

AUSTRIAN MYRIOPODS

Die Myriopoden der österreichisch-ungarischen Monarchie. Von Dr. Robert Latzel. Erste Hälfte Die Chilopoden 8vo. pp xv and 228, plates i-x. (Wien Alfred Holder, 1880.)

THE centipedes, millipeds, and their allies have hitherto not only been neglected by English naturalists, but practically by Continental workers, until the present generation. Our countryman, Newport, indeed (of whom it may be said with justice, that he touched nothing that he did not elucidate and adorn), has secured a permanent

place in the annals of the class referred to; but it is to the brothers Koch, Meinert, and the Italians Fanzago and Fedrizzi, with the Bohemian naturalist Rosický, and some few other writers of less importance, that we have had to look in recent times for anything approaching serious or continued work upon these creatures. In America, Wood and A. S. Packard, jun., have also done good service. The writer of the book now under notice (Professor of Natural Sciences in the Imperial Franz-Joseph Gymnasium at Vienna) has by this sterling treatise at once assumed a place in the front rank of authorities We are not aware of any prior writings of his on the subject, beyond one or two of trifling local interest; but, from his five years' study and collection of material in various parts of Austria and in Western Hungary, it is clear that he is qualified for the task of monographing the species of his country, especially as he has examined nearly all the exponents in Austrian collections and museums. As he says, no work on the *Myriopoda* of Europe, or even of Germany and the Austro-Hungarian Empire, exists; so it is to be hoped that the present instalment towards such a desideratum may be from time to time succeeded by others of more extended area.

As regards the preparation, &c, of specimens, Dr Latzel recommends the use of small well-corked glass tubes, containing spirits of wine. Pinned examples are of no use.

Adopting the *Myriopoda* as a separate class (Packard seems alone nowadays in uniting them with the *Insecta*), the following classification is proposed Orders I CHILOPODA, II. SYMPHYLA, Ryder (for the *Scolopendrellidæ*); III. DIPLOPODA, with sub-orders *Chilognatha*, *Colobognatha* (for the *Polyzoniidæ*), and *Heterognatha* (for the *Pauropodidæ*); IV. MALACOPODA (*Peripatidæ*).

The present part discusses the *Chilopoda* only, the flat centipedes, with large sternum, and whose first pair of thoracic feet is transformed into foot-jaws. The common thin yellow *Geophilus*, which sometimes gives out a phosphoric light, is a type of the order Thirty-one genera are recognised, whereof fifteen are European, one American (*Notiphilides*), and one European (*Stigmatogaster*) being described as new, and *Opisthemega*, Wood, renamed *Megopisthus*. Sixty-seven Austrian species are described (*Lithobius*, the largest, with thirty-seven), including many new ones.

It is not within our scope to analyse the specific characters of such a work; Dr. Latzel seems to have performed his task conscientiously and exhaustively, giving the varied stages of development in each case where known ("juvenis," "adolescens," "pullus," and "fetus"), and combining biological and anatomical aspects with the purely descriptive accounts.

The *Myriopoda* have always afforded material for the comparative anatomist, as evidenced quite recently by MacLeod's researches upon the poison-bearing glands of various Chilopods (in the *Bulletin* of the Belgian Academy of Sciences, 2nd series, vol xlv. p 781 *et seq.*), and Voges's scheme for the classification of *Tracheata* (in Siebold and Kolliker's *Zeitschrift fur wissenschaftliche Zoologie*, vol. xxxi. p. 143), &c. Dr. Latzel recognises the importance of this element, and gives some remarkably well-executed lithographs (from his own designs) of such organs as are of general morphological importance, in addition to details illustrative of specific structure. Were it not for the general excellence of Continental work in such matters, we should congratulate Messrs. Hölder upon the result of their part in this matter.

OUR BOOK SHELF

Die Ethnographisch-Anthropologische Abtheilung des Museum Godeffroy in Hamburg. Ein Beitrag zur Kunde der Südsee-Völker Von J. D. E. Schmeltz und Dr med R. Krause. (Hamburg · L. Friederichsen and Co. 1881.)

THIS catalogue of the anthropological section of the Museum Godeffroy in Hamburg is a model of its kind, and from the exhaustive manner in which it is treated the publishers are quite justified in calling the publication as they do in their prospectus a "Handbook of Ethnography and Ethnology of the South Sea Tribes." The Godeffroy collection is probably unique and unrivalled as representing the area to which it is confined, and is another example of what private munificence can accomplish for scientific ends; and though the great merchant house may no longer have their collectors scattered throughout the South Seas, the town of Hamburg now possesses by their exertions the anthropological material which this somewhat bulky volume of 687 pages with 46 plates is found not too large to enumerate. However, this catalogue is not merely an enumeration, but contains much valuable geographical information, and some most useful bibliographical notes, which, in the present absence of any anthropological record compiled in the method and way of our zoological work, is, if not perfect, much to be commended, and not too critically received. The arrangement is geographical, and therefore ethnological in its true sense, as followed in most large museums, the Pitt-Rivers collection being of course a brilliant exception, which is rather designed to exhibit evolution in culture

The first part, "Ethnographische Abtheilung," is written by Dr. Schmeltz, and naturally occupies the largest portion of the volume. Australia is treated first, and then "Oceanien," commencing at New Guinea and terminating with the Sandwich Isles, including not only so large and well known an area as New Zealand, but also amongst others the smaller and much less known Exchequer Isles and Futuna. Of the last-named we are told incidentally that the fauna and flora is allied to that of Samoa. The Gilbert, Marshall, and Caroline Islands are then dealt with, the last very fully. This ethnographical portion concludes with Alaska and a few other various localities, thus showing that in the most special of museums the usual few outside elements obtrude

The second part, "Anthropologische Abtheilung," is the joint production of Messrs. Schmeltz and Krause, the first author treating the photographs and original drawings, whilst Dr. Krause enumerates and describes the osteological specimens. The cranial measurements are most desired by physical anthropologists, and it is to be hoped that some of our own provincial museums which are still behind in that respect, though possibly containing but few crania, will yet, where such can be authentically localised, have the same at once properly measured, and for a method, the lately-published Catalogue by Prof. Flower will supply all that anthropological science requires. Such Catalogues as the one under notice, taken with those of Prof. Flower and General Pitt-Rivers, are in themselves real manuals of anthropology.

W. L. D.

On the Digestive Ferments and on the Preparation and Use of Artificially Digested Food. By Wm. Roberts, M.D., F.R.S. (London: Smith, Elder, and Co., 1880.)

THIS little volume contains the three Lumleian Lectures delivered before the College of Physicians, London, for the present year. The subject is treated in a manner worthy of the reputation of the author. He gives a summary of what is known on the subject of digestion as a function common to animals and plants, treats of the general characters and properties of the digestive juices and their ferments, with an account of the action of each on food material. After many trials the author adopts three solutions for the preservation of his solution of animal ferment, full details of the preparation of which are given. The researches of Musculus and O'Sullivan as to the transformation of starch are given, with the very recent researches on the same subject by Brown and Heron. The subject of the digestion of starch is excellently handled, and any dyspeptic reader would do well to consider the facts and reasonings here so well and clearly given. The second lecture chiefly relates to pepsin and the digestion of proteids; digestive proteolysis; the milk-curdling ferment. The third lecture is devoted to the effects of cooking on food, preparation of artificially-digested food, peptonised materials, the clinical experience of the use of peptonised food, and on the use of pancreatic extract as an addition to food shortly before food is taken. These lectures, though at times technical, may be understood by the ordinary reader, who would often derive advantage from a general knowledge of their contents. As long as man must live on food so long will the proper digestion of that food be of extreme importance to him.

The Niger and the Benueh. Travels in Central Africa. By Adolphe Burdo. From the French by Mrs. George Sturge. (London: Bentley, 1880.)

THERE is a good deal that is interesting in M. Burdo's lively story of his voyage up the Niger and Benueh, partly in the company of Bishop Crowther. He gives many details of the various towns and villages he visited on the banks of the two rivers, and of the appearance and habits of the people he met with, all welcome information in a region on which our information is even yet comparatively meagre. M. Burdo's journey was made in 1878.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.*

The Editor urgently requests correspondents to keep their letters as short as possible. The pressure on his space is so great that it is impossible otherwise to ensure the appearance even of communications containing interesting and novel facts.]

Smokeless London

I HAVE read the letter of Mr. Scott Moncrieff in NATURE, vol. xxiii. p. 151, with much interest, and am satisfied that his data and conclusions are substantially accurate. This conviction is based on some experience in the commercial distillation of coal.

One difficulty will arise which should at once be foreseen and provided against, or it may be exaggerated into a big bugbear by that class of self-styled "practical" men who oppose to every innovation the inertia of their own self-sufficient stupidity. The semi-coke remaining in the retorts, when only one third of the volatile constituents of the coal has been run off, will be highly inflammable, and display this property by a great outburst of lurid flame and dense smoke when the retort doors are opened for discharging, and unless the withdrawn charge is immediately quenched there will be a veritable Inferno where it falls. This is merely a matter of practical detail admitting of easy remedy where there is ability and willingness to grapple with it.

A more serious difficulty is likely to arise in London from the peculiar position of the gas companies. They are suffering from commercial congestion due to a plethora of prosperity, and receiving no stimulation from wholesome competition, they display very low commercial vitality. The public welfare is no business of theirs.

It is otherwise in those towns that are sufficiently advanced in civilisation and have abolished the gas and water joint-stock monopolies. There the public are helping themselves, and control the management of the Corporation gas works by their election of the members of the Corporation. Many of these towns are foggy and smoky enough for the experiment, and in these such a boon as that offered by Mr. Moncrieff will probably be appreciated, and, being appreciated by those most interested, will be at once practically tested. Birmingham, for instance, is likely to try it. I was there a few weeks ago and saw how they have eclipsed our electric lamps on the Embankment by the gas lamps around their town-hall.

If it succeeds in any one of these towns our companies will surely follow, or if not, so much the worse for the companies.

Stonebridge Park, Willesden, W. MATTIEU WILLIAMS
December 17

I HAVE read with great interest Mr. Scott Moncrieff's scheme for "Smokeless London" propounded in your last issue. I would ask however—Is he satisfied that the coke would be smokeless when only 3333 feet of gas per ton has been extracted from the coal? E. R. F.

London, December 20

Climates of Vancouver Island and Bournemouth

I THINK it very probable that your correspondent Capt. Verney is right about the climate of Vancouver's Island. My only sources of information were maps of isothermals in Keith Johnston's and Phillips' Atlases, which show the *mean* temperature about the same as that of the south of England, while the *winter* temperature is shown as being decidedly colder, and it was to this I more especially referred. The mainland of British Columbia is undoubtedly colder than that of Western Europe, but Vancouver's Island itself and the adjacent sea may be really milder, and if so it is another proof of the great power of the returning Japan current.

I shall be very glad of Prof. Haughton's criticisms on my hypothesis, and in the mean time will only say: 1. That unless Bournemouth is *never* cooled by north and north-east winds, any amelioration of the climate of the Polar regions would certainly benefit it. 2. That as by my hypothesis the entrance of two new gulf streams into the Arctic Ocean would entirely prevent the formation of ice, the return currents that would undoubtedly be produced would *not be cold currents* in the sense in which they are now, as they would probably be always considerably above the freezing point. ALFRED R. WALLACE

Geological Climates

IN relation to the discussion as to the importance to be ascribed to the distribution of certain trees and plants in the determination of geological climates, it may interest Prof. Haughton and Mr. Duncan to know that a specimen of the Australian *Araucaria Cunninghami* is now growing on one of the slopes of the Marlstone Hills near Belvoir Castle, in North Leicestershire, a position it has occupied for upwards of forty years. It has attained a height of about thirty five feet. Having survived (without other protection than that afforded by the wooded heights about it) the cold of the winters of 1860 and 1879, its capability to withstand a greater degree of cold than is ever experienced in our southern counties may be with confidence asserted.

Masses of a true and very characteristic bamboo, *Bambusa metaké*, are now growing vigorously and spreading rapidly on the same estate, the long elegant and slender canes and the delicate green foliage of this variety of bamboo not having suffered in the slightest degree from the severe frost of last winter or the early and equally trying severity of this. *Arundinaria falcata*, the bamboo found as high as the snow-line in the Himalayas, has also proved hardy at Belvoir, but it has been displaced as an ornamental plant by *B. metaké*. *Arundo donax*

often throws up clustering bunches of canes that reach a height of sixteen feet in one season. Associated with *Arundo conspicua* and *Gynecium argentum*, the above interesting and handsome plants give quite a tropical aspect to some of the hill-sides of this northern county. WILLIAM INGRAM

Belvoir, December 20

The Appulse of Jupiter to a Fixed Star on November 20

REFERRING to a request appearing in NATURE, vol xxiii p. 158, I may say that the approach of Jupiter to B D + 2°97 was well observed here, and I found that the star, when perpendicular to the belts, was 4″ 05 distant from the northern limb. The definition was good, and the measure, I should say, pretty exact

It was a strange and beautiful sight, Jupiter appearing with *five* satellites, though, at the same time, the different aspect of the star compared with that of the moons was very striking The light of the former was however very sensibly affected by the glow of the great disk near it, and it looked no more than 10 magnitude JOHN BIRMINGHAM

Millbrook, Tuam

British Earthquakes

MAY I ask leave to offer a few remarks on the leading article on British Earthquakes which appeared in NATURE, vol xxiii, p. 117. The author brings out very strongly the apparent connection between great lines of jointing or faulting and earthquake movements, and points out the great fault which traverses Scotland from sea to sea as a case in point Now I had this same question before the British Association this year, and exhibited a map illustrative thereof I had further, following up a theory submitted by me to the Royal Irish Academy, on the Correlation of Coast-Line Directions, and published by that body, drawn up on a Geikie's Geological Map of Scotland certain of those correlated lines, and on a smaller map of the British Isles had indicated both the lines in question and the localities wherein earthquakes have been noticed in later times, more essentially since 1860 One of those lines crosses the district about Comrie, and at the moment (August, 1880) could hardly be pointed out as in any notable way supporting the connection sought to be established between coast-line directions and earthquake localities. But the recent earthquakes in the north of Ireland and in Scotland go far to do this, as the direction shown by me both agrees with the great fault mentioned by the author of the paper on British Earthquakes in direction, and also fairly shows the direction of the earthquake band or zone, which apparently extends from Londonderry across Scotland This direction is exactly at 40° with the coast line direction between Carnsore Point and Wicklow Head, as shown on the accompanying map.

I may add that having had occasion to examine Prof Hofer's memoir on the "Erdbeben Karntens und deren Stosslinien," and to compare his lines with those given on the map of Europe exhibited by me at the British Association meeting of this year, I find some very remarkable concordances as regards directions, which, having submitted to him, he quite recognised. I consider therefore that this memoir, Prof. Geikie's very remarkable article on the Volcanoes of North-Western Europe, and this late article on British Earthquakes, all point more and more distinctly to the importance of jointing and fissuring in connection with volcanic and earthquake action, and so far go in support of the theory submitted by me. J P O'REILLY

Royal College of Sciences, Dublin, December 14

A General Theorem in Kinematics

I AM very much obliged to Prof. Everett and Mr. J. J Walker for having taken the trouble to point out that the theorem which I communicated to NATURE is, *so far as it relates to uniplanar motion*, already known. I am indebted to Prof. Unwin for more complete information on the subject He tells me that the theorem (for the uniplanar case) has been employed by German engineers in the discussion of stresses produced in moving pieces —exactly the use of the theorem which naturally presents itself. Moreover, the theorem (for the uniplanar case) will be found in § 198 of Collignon's "Cinématique," as well as in other foreign books, but not, so far as my information goes, in the work of any English author. None of your correspondents or of mine are however able to say that the *general* case was previously known.

The simple method of proof given by Prof. Everett is that which I had used nearly a month ago in a paper which I wrote (and have since read) for the London Mathematical Society.

I may mention in connection with this subject a kinematical theorem which Mr Kempe communicated to NATURE some time back. I find that this theorem comes properly under a general theorem which holds for the areas of roulettes It can be easily proved that the areas of the most general kinds of roulettes follow exactly the law of circular transformation which Steiner proved to hold good for the areas of pedals. For this theorem of Steiner's see Williamson's "Integral Calculus," p. 202, third ed.

Mr. Kempe's theorem (as also Holditch's) is an immediate consequence, since every possible uniplanar displacement of a body can be produced by epicycloidal motion. Mr. Williamson, justly describing Mr. Kempe's as "a singularly elegant theorem" (*ibid* p. 210), arrives at it quite differently.

A Correction

IN NATURE, vol. xxiii p. 44, Prof. Young has published some experiments proving that the thermo-electric power of a platinum-iron couple is to be observed in vacuo as well as in air, this fact is said to be contradictory to the results given in my papers I presume that some error has caused this statement, as I never and nowhere asserted that the thermo-electric power is dependent on the surrounding gases. I have, on the contrary, stated (*Phil Mag.*, October 1880, p 294) that no such influence has been hitherto observed Thus the experiments of Prof. Young do in no way contradict my views.

University of Vienna FRANZ EXNER

Jelly Fish

ON November 3, in the B.I S N. Co 's steamer *Arcot*, Capt Stevenson, while in lat. 16° 50′ N, long 55° 45′ E, with the Kuriyan-muriyan islands to the north, thirty to forty miles and three days out from Aden to Karachi, we passed through a vast quantity of brown anemones, the ordinary bell shaped jelly-fish and strange worm-like (apparently) jelly-fish, floating on and just below the surface. These were first noticed about five in the afternoon, and we were still amongst them when we went below to dinner at six, the vessel steaming about eight knots The anemones were only peculiar in that they appeared to be rounded at the base and without the ordinary flat surface for adhering to rock or stone; they were in vast numbers and had the feelers expanded The worm like or centipede-like jelly-fish were from six to eight feet long and as thick as a man's wrist. They appeared sometimes singly, sometimes many twisted together, they were in slow feeble snake-like motion All agreed that they were ribbed in appearance; but there was a difference of opinion as to the colour It was described by some as that of the sea, by others as violet, brown, or purple. Each apparent rib was divided from those next it by a bar of lighter colour.

At night the sea was bright with many phosphoric lights of many shapes, so we were perhaps still passing through the mass. There was a dead calm at the time

The captain has read this account and stated it to be fairly correct F. C. CONSTABLE

Karachi, Sind, November 8

MR. PLIMSOLL'S CURE FOR COLLIERY EXPLOSIONS

LET us suppose a person actuated by very powerful motives, who desires to solve the most difficult mathematical problem of the day, and who, after having neglected to acquire the most rudimentary knowledge of his subject, and after having contented himself with seeking the company of land surveyors, and trying to entrap civil engineers into conversations about it, suddenly startles the world with the cry of Eureka! Eureka! Eureka! should we, or should we not, be inclined to regard his solution with respect?

Mr. Plimsoll has done for the mining world exactly what our suppositious person would have accomplished for the mathematical one. In an article contained in the December

number of the *Nineteenth Century*, under the title of "Explosions in Collieries and their Cure," he lays before the readers of that magazine an account of the praiseworthy motives which impelled him to seek some means of preventing these horrible disasters, he tells them plainly that he knows little or nothing about the subject, and he recounts what steps he took for the purpose of supplying the want of that knowledge to some extent He says — "In my hope that the resources of chemistry might supply a solution of the problem which has so long perplexed everybody, I have made it my business from time to time to seek the society of practical chemists as well as of purely scientific men whose business it is to teach chemistry I have seen several amongst the former who are engaged in calico-printing works, lead-works, &c, and have sought, by getting them to talk about chemistry, and by so to speak lying in wait myself for some hint in their conversation, for something which might supply the missing link"

Mr Plimsoll then gives an account of how he travelled over the painfully disappointing road of trying to "unmask" the fire-damp, to "make it visible to the eye like smoke or steam," and to indicate its presence by means of a collodion balloon filled with the light carburetted hydrogen and put into a vertical recess glazed in front where it "would float upon the stratum of common air because filled with the lighter gas, but would remain at the bottom of the stratum of gas because kept down by the weight of the envelope inclosing it."

He says of the fire-damp indicator —"A delicate instrument has been invented, constructed on the principle of the diffusion of gases, but as this would require the application and careful observation of anybody using it, and as all it shows can be equally ascertained by watching the elongation of the flame on the safety-lamp, I pass it by."

He next asks, "Can this gas be absorbed?" and gives an example of what he means by describing the strong affinity which quicklime has "for hydrogen in the form of water", and lastly, he puts the question. "Supposing all these branches of inquiry to result unsatisfactorily, whether this gas should be loaded or neutralised in some manner that should render it non-explosive?"

We will pass over the incentives which our author brings forward with the view of stimulating men of science to undertake the work of discovery That these incentives are strong enough in all conscience we who heard the dreadful sound of the explosion at the Naval Steam-Coal (Penygraig) Collieries as we lay awake shortly after midnight on Friday last can testify from experience. A few hours later we breathed the fatal after-damp in a sufficiently diluted form to produce only headache and nausea: we looked upon the blackened remains of the victims as they lay or knelt on the ground, some having been hurled from a distance and having nearly every bone in their bodies broken, others having their coats tightly drawn over their necks and mouths and their faces buried in the dust, and still others actually kneeling, having their knees drawn more or less closely up under them, their hands pressed on their mouths and their faces also in the dust We saw nine fine horses that had been struck down where they stood in their stable never to rise again; one that had started off at a mad gallop, and been arrested in six yards by a fall of roof due to the blast which startled him, his legs and his whole body in an attitude of fierce action resting on the top of the fall, and his head laid gently on one side; two others lying on their backs with their legs in the air; another that had turned round in his shafts by some extraordinary convulsion, so that he faced the load he was drawing, while his body, with head erect, was twisted in between two props at the side of the road; and, lastly, a little donkey denuded of harness and tossed like a rag on to a heap of rubbish. We saw many of the bodies carried to the bottom of the shaft and sent to the surface, and others being carried from the pit to the homes where they lately dwelt, we heard the weeping of the bereaved ones; we saw one little knot of mourners from our very window, and since we began to write, as they gathered at the end of a row of houses, were joined by others bearing a coffin on their shoulders, and proceeded slowly down the road and out of sight, while the plaintive Welsh hymn that never fails to accompany such a procession rose and fell on the ear, and died away fitfully amongst the hills.

If any one can see and hear all this and more and remain unmoved, his natural affection is dead, and Mr Plimsoll's appeal will be made to him in vain Happily there are many whose hearts are wrung when they see or hear of the sufferings of their fellow-men, and who are always ready and willing to respond to such a cry

We will now turn to the second part of Mr Plimsoll's article, where we find his account of the manner in which he proposes to prevent "half, or it may happily prove even more than half, the number of explosions" He describes it in the following words —"I do not propose to alter anything in existing arrangements in the suggestion I am about to offer, but only to supplement them Let the present system of ventilation remain as it is in all its vigour, but in regard to the gas which escapes it, gets behind it, and accumulates in the upper and the waste portions of the pit, can we not go arm in arm with Nature in this matter, as we do in the others, and follow the gas whithersoever it goes and thus, in Lord Bacon's words, by obeying Nature learn how to conquer her?

"It goes to the highest part of the pit, therefore into the exhausted spaces I would work with this tendency, and, as in the case of water, a large hole is dug called a 'sump,' to collect the water at the bottom of the pit and so facilitate its removal by the pumps, so I would make a hole or sump for the accommodation of the gas; but as the water is heavy and lies upon the floor, and has the sump for it made in the floor, so my hole or 'sump' to gather the gas should be in the roof of the mine, and that in the highest accessible places.

"If it were certain that the water will run into the hole or sump dug for it in the floor or the lowest part of the pit, then it is equally certain that the light carburetted hydrogen would rise in the 'sump' or hole dug for it in the highest part of the workings of the pit

"I would then place a vertical tube with an open trumpet-shaped mouth, something like the funnel or chimney of a locomotive, in this place, and of such a length that the open mouth (which should be protected with a louvre covering or cap to keep out the dirt) should reach up very near to the roof; the bottom end of this pipe or tube I would continue to the bank of the pit; and as in the case of water you proceed to remove the accumulation by a water-pump, so in this case I would pump out the accumulation of light carburetted hydrogen by means of an air-pump; probably a small fan like that used in foundries would do as well, or even better

"This air-pump or fan could easily be worked by a strap from the winding-engine, or by hand It would require assistance during the daily drawing out of the pipe the atmospheric air which would fill it when the gas was exhausted from the mine. I ask your common sense, could you not as certainly in this way draw off every cubic foot of gas in the mine as you now can certainly remove the water from it?"

Mr. Plimsoll summarises in the following manner —

"1. Is it not a fact that the light carburetted hydrogen does and will seek the highest place of refuge open to it in the pit? 2. Is it not a fact that at this moment there is scarcely a coal-mine which has not gas in its goaves and highest parts? And 3 Is it not clear that by thus tapping the highest places it can as surely be drawn off as water can be pumped out of a pit?"

It would be impossible to controvert all the statements that Mr. Plimsoll makes regarding the properties of fire-damp, its tendency to rise to the highest point, and so on; he has supplied himself with all the knowledge necessary to understand its behaviour when it is found in easily manageable quantities. But what are we to think of his proposal when we come to deal with such quantities as 1000 and 2000 cubic feet per minute? Two hours after the explosion at the Naval Steam-Coal (Penygraig) Colliery we estimated the amount of fire-damp coming up the upcast at 1100 cubic feet per minute, and this is doubtless the normal quantity when the colliery is at work Dinas Colliery, which adjoins the last-named one, always produced about 1000 cubic feet per minute for some years before the explosion on January 13, 1879, Llwynypia Colliery, which adjoins the Naval Steam-Coal Colliery on the other side, produced 2000 cubic feet per minute for some years, but its output of coal is now less, and consequently its production of gas has decreased

But where does this gas come from, and how is it disposed of? In following one of the subdivisions of the air-current from the point where it leaves the main intake air-current to the point where it returns to the main return air-current we observe the following phenomena On reaching the first working place the air is still apparently as pure as it was when it left the surface; about the fifth or sixth place it begins to show the first symptoms of gas on the small flame of a glass safety-lamp (it is still invisible in a Davy lamp), at the tenth place the cap is quite apparent even to the unpractised eye, at the fifteenth place it is say $\frac{3}{16}$ of an inch in height, and at the twentieth place it is a $\frac{1}{4}$ of an inch. This is enough, and the current returns towards the upcast shaft without passing through any more places At the point of its junction with the main return air-current its cap remains exactly the same as it was when it left the last face We have ourselves verified these observations hundreds of times in different mines. The number of places through which the air must pass in order to obtain a given proportion of gas varies according to the rate at which gas is produced in the mine in question, and the volume of air passing along the faces.

In the most fiery mines we can generally follow the air-current from the surface, and return with it again to the surface after having passed along the working places without having seen the least accumulation of explosive gas. This is the rule; a cavity left by a fall of roof and containing explosive gas is the exception, and not only is no work allowed to be carried on near it, but means are taken to ventilate it as quickly as possible

How then could Mr Plimsoll's method be applied under these circumstances? Should we slacken the ventilation in order to give the gas time to rise to the roof, and after it got there to give it a chance of finding its way to a sump excavated for it somewhere or other? If so we should have streams of explosive gas travelling along the roof of the working places, and our dangers would be increased a thousandfold. We do not know what kind of mines those are in which Mr. Plimsoll has seen a stratum of explosive gas along the roof of the airways, but we should prefer not to have anything to do with them, even were his method applied for the purpose of drawing off the gas.

Let us take the explosion that has just occurred in the Rhondda Valley as an example. About ten months ago the two shafts, which are about 1111 yards apart, and over 400 yards deep, were connected together by an approximately straight heading, which is driven nearly level in coal from each shaft for say 520 yards, and descends the slope of a fault for 60 yards. The coal in one shaft is 30 yards below the level of that in the other shaft, and the surface of the ground at the top of the former shaft is 188 feet higher than at the latter. The fault forms a natural boundary between the workings of the two shafts, and, except for purposes of ventilation and communication, they were treated as distinct collieries. The workings are ranged on each side of the straight heading, there being four districts at the lower level (three on the right hand and one on the left, looking towards the higher shaft), and one district at the higher level (on the right hand side, looking in the same direction). The natural direction of the air-current is from the lower to the higher shaft The natural air-current gives a volume of about 30,000 cubic feet of air per minute at the present moment, and we are informed that when the fan was at work the volume was between 60 and 80,000 cubic feet The envelope of the fan was destroyed by the explosion, and the natural ventilation had to be depended on for the explorations so far as they have been carried.

Soon after midnight on the morning of Friday last there were somewhat over one hundred men and boys busily employed underground five were at the bottom of the upper shaft, four at the bottom of the lower shaft; seventeen or so were on the straight heading about half-way between the fault and the upper shaft, twenty-four were in the left-hand workings of the lower shaft; several gangs of from three to six were in each of the other three small districts of the lower workings; fifteen or so were in the right-hand workings constituting the only district in the upper pit; some were cutting coal, others were blasting down roof, some were filling rubbish, others were stowing it into empty places, and here and there a horse and his driver were proceeding along the roadways with short trains of full or empty waggons

No explosive accumulation of gas is said to have been found in the mine when it was examined a few hours previously, and two men, who came up only a few minutes before the explosion, had not heard of any unusual occurrence The mine is a very dry one, and there is abundance of very fine coal-dust to be found everywhere on the roadways.

A sudden shock was felt, a veritable hurricane swept through every passage and every open space communicating with the air-ways, a "darkness that might be felt" ensued for an instant, then a gleam of brilliant light accompanied by a shower of molten and red-hot dust, then darkness again, and all was still

During the interval between the raising of the dust and the passage of the flame some of the men, who evidently knew what had occurred, pulled their coats over their necks and mouths and staggered outwards, but fell after they had gone at most six or eight yards; others, as we have said, knelt down, covered their faces with their hands, and buried their mouths in the dust and small coal on the floor; the terrified horses made a few mad plunges, and then the Angel of Death breathed upon them all, and they remained transfixed in the positions they had assumed at that fatal moment. Only five men who were engaged in workings close to the downcast shaft escaped alive. They were rendered insensible by the after-damp, but recovered consciousness before the exploring parties reached them, having been revived by the fresh air which immediately flowed into the downcast shaft after the explosion was over.

We ask now where was the fire-damp accumulated that could produce so widespread an explosion, and at what part of the colliery would Mr. Plimsoll have placed his apparatus for the purpose of pumping it out?

The flame ramified into every district of workings both in the upper and lower pit, and left unmistakable tokens of its presence in the form of crusts of coked coal-dust on the timber, on the coal, and on some of the men's bodies.

It is evident that Mr. Plimsoll has remained unnecessarily ignorant that many men have been engaged in working out the problem he has attempted to solve. Let him go back to the many volumes of Parliamentary evi-

dence for information that will enable him to avoid all his useless work in trying to find means of "unmasking" or absorbing the gas; let him take up Faraday and Lyell's report on the Haswell Colliery explosion of 1844, and he will find his own proposal described in every essential detail, as well as a hint thrown out that coal-dust has much to do with explosions; let him peruse the copy of the report addressed to the United Committee of the Coal Trade by the Special Committee appointed to take into consideration Faraday and Lyell's report, and he will find the opinion expressed by the practical men of that day regarding the very plan he now brings forward as original.

But why should he labour through all that mass of reading and more than we have named, when he can find all that is of any value on the subject condensed in that most admirable dissertation, entitled "Rapport de M. Haton de la Goupillière (Ingenieur-en-chef des Mines, Professeur d'Exploitation des Mines à l'École des Mines), au nom de la Commission d'Étude des Moyens propre a prévenir les Explosions du grisou" (Paris Dunod, Editeur, Quai des Augustins, No. 49, 1880) In that volume he will find an account of all his own plans and those of many others, as well as much valuable information that will prove of inestimable value to him if he should decide to pursue this subject to its legitimate conclusion, as we most earnestly hope he will.

Mr. Plimsoll wrongs the scientific and mining sections of the community when he charges them with so much indifference. In England, in France, and in Belgium there is at present a Government Commission considering the subject of his article, viz. "Explosions in Collieries and their Cure," and collecting evidence which will be of great value in enabling us to approach nearer to the mark we are all aiming at

As usual the Royal Society travels in the van, and to our certain knowledge has given the sum of no less than 255*l.* within the last seven or eight years towards assisting in experiments which are being made with the view of throwing light upon the subject.

Similarly each of the Mining Institutes is eagerly canvassing every scrap of useful knowledge that may tend to lessen the risks of mining, and especially of explosions.

Lastly, in Germany we have also activity, and we can recommend a perusal of a pamphlet entitled "Die Verhuttung von Explosionen schlagender Wetter in Steinkohlenbergwerken," by Dr Adolf Gurlt, Bergingenieur, Bonn: Verlag von Max Cohen und Sohn (Fr Cohen), 1880 This pamphlet ends with the following words, in which it appeals to thoughtful miners We would extend the same appeal to one and all:—

"So mogen denn alle denkenden Bergmanner ihre Krafte vereinigen um dem verderblichen Feinde des Kohlenbergmannes, dem Grubengase, diesem Moloch, welcher noch fortwahrend so viele frische Menschenleben verschlingt, in Zukunft seine Opfer nach Möglichkeit zu entreissen."

If really safe safety-lamps were introduced that could not under any circumstances ignite an explosive mixture of fire-damp and air; and if at the same time the use of an explosive or other agent that produced no flame were substituted for that of gunpowder or dynamite, we might be comparatively free from explosions.

Thus far however neither the one nor the other of these desirable consummations has been attained.

On the other hand, if we could entirely eliminate explosive accumulations of fire-damp and air from our mines we should expect, according to the most generally received opinions, to be able to use naked lights and to fire shots wherever we had a mind to do so. Naked lights we might use under these circumstances; but we should protest in the strongest terms against blasting in the presence of dry coal-dust alone. The *rôle* of that agent has not yet been officially recognised, at least to the extent of framing special regulations to assist in dealing with it; and until it is so recognised we venture to assert that explosions will continue, and that the same impossibility of explaining them, save by the assumption of simultaneous eruptions of fire-damp in different parts of the workings, will continue to be experienced

That this is an illogical method of accounting for them may be gathered from the fact that the Risca explosion of July last required no less than three simultaneous eruptions to explain it The Penygraig explosion would require one in each district, but we say this without prejudice to the evidence either direct or circumstantial that may yet be forthcoming to prove the existence of explosive accumulations in one or more places in the workings.

In conclusion we would say that the Penygraig explosion cannot be explained by the fire-damp hypothesis alone, explosive accumulations may have been accidentally ignited by a shot, or by a defective safety-lamp, and so have originated the explosion, but something else than fire-damp, something whose presence was entirely ignored, took up the flame, carried it to the innermost and to the most extreme limits of the workings, and was in all probability the cause of 90 per cent or more of the deaths that ensued. Need we state our absolute conviction that that obscure agent was coal-dust?

W. GALLOWAY

COL. PRSHEVALSKYS' RECENT JOURNEY

THE new number of the *Isvestia* of the Russian Geographical Society contains the long-expected letters from Col Prshevalsky on his adventurous journey on the frontier of Tibet We have already referred to Col. Prshevalsky's work, the following further details will be of interest —His last news were dated from Hami, whence he proposed to go south-east to Tsaidam But it was impossible to find a guide a Chinese, given for this purpose by the Hami authorities, left the expedition some fifty miles from the town, after having led the travellers into a region full of great ravines M Prshevalsky, confident in his eleven companions, resolved to find his way himself by sending every day two men on horseback for distances of thirty and fifty miles round to discover the best direction. The advance was very slow, and the travellers spent one month and a half in the mountains south of Sa-djeou, discovering the high mountain-ranges to which they gave the names of Humboldt and Ritter. After a march of 190 miles they arrived at Kourlyk in the Tsaidam, but here also they were badly received, and could not find guides, owing to the secret influence of the Chinese. Finally M Prshevalsky told the chief of Kourlyk that he would take him as guide to Tibet if another guide could not be found, and on the following day the guide was found

On September 24 the travellers left Tsaidam Again the guide led them into impracticable tracts near to the Blue River, so that M. Prshevalsky's expedition was compelled again to seek its own way After having crossed the Blue River at its sources, they climbed the high plateau of Tan-la, after having crossed the 16,800 feet high pass across the border-range, which was covered with snow in October On the passage they were attacked by the nomad tribe of Egrays, but the companions of M Prshevalsky gave them a hot reception, and the Egrays fled, leaving four killed and several wounded.

Descending from the Tan-la ridge, the expedition continued its way to Lassa, but at the Nabchou settlement, 160 miles distant from the capital of the Dalai-Lama, they were met by Tibetians, who declared that the expedition could not be allowed to go further without a permission from the Lassa authorities, a thousand soldiers were assembled at Nabchou M. Prshevalsky gave his consent to await an answer from Lassa, and stayed at

Nabchou, buying food from the Tangoutes, who consider themselves as under the rule of the governor of Sining. Twenty days later the answer arrived; a messenger from the Dalai Lama, accompanied by seven officers, entreated M. Prshevalsky to return, saying that the whole population of Lassa was very excited against the strangers, as it was declared among the people that the expedition intended to steal the Dalai-Lama himself and extirpate the Buddhist religion. A conflict with the inhabitants of Lassa being most probable, M. Prshevalsky was compelled to return. All December and January were spent on the road to Tsaidam, the distance from Nabchou to Tsaidam being 560 miles. Progress on this high plateau (14,000 to 16,000 feet) was very difficult; out of thirty-four camels twenty died, and the collections were conveyed on horseback; the men mostly went on foot. We need scarcely say that the scientific collections and observations are of a great value.

On March 20 M. Prshevalsky reached the Chinese town of Sining, close to Lake Koko-noi. After having received permission from the governor of the province to go to the Hoang-ho, however, without crossing it, M. Prshevalsky sent his collections to Alashan, and went east to the banks of the Yellow River, which are fifty-six miles distant from the town of Donkyr. He reached them at the Gomi settlement. The river, 450 feet wide, and 8000 feet above the sea-level, is rapid (5 feet in a second). Its valley cuts deeply into a great deposit of clay, gravel, and boulders, the abrupt walls of which, along the banks of the main river, being 1600 feet high, and no less than 1000 feet along the banks of numberless tributaries. The journey across these gigantic ravines with abrupt walls (quite like those of the loess in the lower parts of the Hoang-ho) was most difficult. After a journey of 130 miles up the Hoang-ho, M. Prshevalsky reached a lofty mountain-range, which is cut through by the river, and probably is a continuation of the Burkhan-buda range. Further advance along the banks was impossible, and M. Prshevalsky not having a guide for crossing the range was compelled to return and soon reached the town Gui-domi, situated on the left bank of the Hoang-ho, forty miles below Gomi. The natural history collections from the Upper Hoang-ho are very rich: 260 species of plants, many fishes, and 500 birds. The astronomical and barometrical observations are numerous. M. Prshevalsky did not reach the sources of the Yellow River, and he supposes that they cannot be reached otherwise than along the Tibetan plateau; he doubts however that the Upper Hoang-ho makes so great a bend as it is usually shown on our maps.

The last letter from M. Prshevalsky is dated Gui-ta-din, on the Upper Hoang-ho. As is known, he returned *viâ* Alashan, and is expected at St. Petersburg by the end of January.

MICHEL CHASLES

THE news of the death of Michel Chasles, perhaps the oldest and best-known mathematician in Europe, will be everywhere learned with deep regret. For the fifty-five years over which his writings extend he has devoted himself with persistent industry to the history of geometry and to the perfection of those geometrical methods with which his name will be always associated. The "Aperçu historique sur l'Origine et le Développement des Méthodes en Géométrie," which in fact forms an elaborate history of the subject from the time of Thales and Pythagoras to the beginning of the present century, is the best known of his works; it was first published in 1837, and a second edition appeared only a few years ago. His restoration of the Porisms of Euclid was published in 1860. The last great work of Chasles related to the investigation of the number of conics satisfying any five conditions: the special method which he invented for these researches, termed by him geometrical substitution, involved the consideration of the characteristics of systems of conics, *i.e.* of the numbers of conics satisfying four common conditions and (1) passing through an assumed point, (2) touching an assumed line.

In 1865 Chasles received the Copley medal of the Royal Society; this medal has, since its foundation in 1731, been given only five times for discoveries in pure mathematics, viz., in 1784 to Waring, in 1814 to Ivory, in 1841 to Sturm, in 1865 to Chasles, and in the present year to Sylvester.

In 1846 Chasles was appointed to fill the new Chair of Modern Geometry, founded by the Faculty of Sciences at Paris; and as a professor he exerted personal influence over the younger geometers of that time, which has since been apparent in their writings, although the effect of the geometrical methods to which he devoted his life is chiefly visible in the works of the Italian and German mathematicians. He was the inventor of the term "anharmonic ratio," but not of course of the ratio itself, which was known to the ancients. Chasles's memoirs on the attraction of ellipsoids are well known to English mathematicians and physicists; and a translation of his memoirs on Cones of the Second Order, and Spherical Conics, was published in Dublin in 1841 by Dr. Graves, now Bishop of Limerick.

Most of our readers will remember how in 1866 Chasles was deceived by M. Vrain Lucas by what were called the Pascal forgeries, and they will also remember how honourably he extricated himself from the matter, and did all in his power to repair the mischief done. The forger was convicted and sentenced to two years' imprisonment; and not a shadow of suspicion was ever thrown upon the honour or good faith of Chasles.

Scientific visitors to Paris will miss a well-known face at the Academy and a kind and hospitable friend. Till quite recently Chasles seemed as active as ever, both mentally and physically, and it was only last September that he issued a new edition of his "Géométrie supérieure." He was a Foreign Member of the Royal Society and of the Cambridge Philosophical Society.

THOMAS RYMER JONES, F.R.S.

THE late Professor of Comparative Anatomy at King's College, London, whose death is announced, was born about the year 1820. He studied for the medical profession at Guy's Hospital, and took the diploma of the Royal College of Surgeons, London, in 1833. A chronic deafness unfitting him for the active pursuit of his profession, he devoted his attention exclusively to comparative anatomy. Some of his earliest papers were on the dissections of a tiger (*Proc.* Zool. Soc. 1834) and of an agouti (*Proc.* Zool. Soc. 1834). He was the first Professor of Comparative Anatomy at King's College, and was Fullerian Professor of Physiology to the Royal Institution in 1840. He was Assistant-Secretary to the Section of Zoology and Botany during the eighth meeting of the British Association held at Newcastle-upon-Tyne in 1838, the president of the section being Sir W. Jardine, the secretaries J. Edward Gray, Richard Owen, and John Richardson. This meeting was marked by the presence of Christian Gottfried Ehrenberg, who laid before the section a copy of his famous work, "Ueber Infusionsthierchen," making at the same time a short statement as to his views of the alimentary canal of the polygastric infusoria. These views were, in the discussion which followed, criticised by Rymer Jones, who stood almost alone among the British naturalists in opposing them. In 1838 the first part of his "General Outline of the Animal Kingdom" was published by Mr. Van Voorst, happily still among us. It was completed in ten or twelve parts, and was illustrated

by really beautiful woodcuts This work marked an era in the study of zoology and comparative anatomy in our country. True it is that the information of the author was mostly borrowed; true that he had no great familiarity with the work of the German naturalists of the time, true that the book will not bear to be appealed to now but forty years ago it was the best book of its sort in England, and the generation has not as yet quite passed away which learnt from its pages We have altered since then, both in the manner and the matter of our teaching of comparative anatomy, and for the better no doubt, but after another forty years our systems may too have seen their day It may be conjectured that this book was in advance of its day, for an eminent writer, in reviewing it in 1839, objected to Rymer Jones' facts about the Infusoria, and declared he still placed confidence in Ehrenberg's observations, while he criticised his description of *Volvox globator*, and believed this "Infusorian" had nutritive organs, mouth, eyes, &c.

Prof R. Jones was an extensive contributor to Todd's "Cyclopædia of Anatomy and Physiology," writing no less than twelve of the articles on comparative anatomy. He was the author of at least one work on popular natural history, called the "Aquarian Naturalist." He was an excellent lecturer, and though never rising to the highest rank as a biologist, well deserves this passing notice in our columns

FRANK BUCKLAND

FRANCIS TREVELYAN BUCKLAND was born on Dec 17, 1826 He was the eldest son of the Very Rev Dr. Buckland, Dean of Westminster. As a boy he was a constant companion of his father in the latter's geological excursions, he was a scholar of Winchester College and a student of Christ Church, graduating M A of Oxford in 1848 About this date he entered St. George's Hospital as a student of medicine, taking the diploma of the Royal College of Surgeons, London, in 1851, becoming house surgeon to St George's Hospital, and lastly receiving the appointment of assistant-surgeon to the 2nd Life Guards, a position he held until 1863 He seems to have been always well liked in his regiment, gaining the character of a pleasant, good-natured, sociable fellow Although fond of all that pertained to natural science, he was in no sense of the word a profound naturalist, he could seize with alacrity the popular side of a scientific question, but he seldom went deeper. Perhaps the most scientific work he ever accomplished was the editing, in 1858, of his father's work on "Geology and Mineralogy," published as one of the Bridgewater treatises. He was the author of some pleasant volumes entitled "Curiosities of Natural History," was a constant writer in *Land and Water*, and an occasional contributor on subjects of economic zoology to the daily press On the subjects of fish and fish-culture he was an authority, and it will be remembered that he had an interesting museum in connection with the subject at South Kensington. For his labours in this direction he received several honourable distinctions from France, and in 1869 he was appointed by the British Government one of the Inspectors of Salmon Fishing for England and Wales. He was also one of the Commissioners appointed to inquire into the Crab and Lobster Fisheries of this country, and the results of this Commission culminated in the useful Act regulating the oyster, crab, and lobster fisheries of the kingdom, which received the Royal assent in 1877.

One notable event of his life was the discovery he made in 1859 of John Hunter's coffin in the vaults of St. Martin's-in-the-Fields, which was re-interred at the expense of the Royal College of Surgeons in Westminster Abbey.

Familiarly known by a large circle of friends as Frank Buckland, he has left them while still in middl life, and it will be long ere they look upon the like of poor Frank again

NEW GUINEA[1]

II

THE various accounts of the natives given throughout these volumes leave an impression of vagueness that is very unsatisfactory The mixture of races in various parts of New Guinea is no doubt great, but we cannot help thinking that there is a well-marked Papuan type, and that its head-quarters are in this great island Signor D'Albertis seems to attach too much importance to minor peculiarities. He continually mentions small differences in the features, the hair, the form of the skull, or the stature, as implying a radical difference of race, forgetting that such differences are found among every people and in every country, and that on this principle we might establish a dozen different "races" in Europe. Taking the term Papuan in a broad sense as including all the dark-skinned woolly or crisp-haired tribes of the Western Pacific, it seems clear that New Guinea is very largely peopled by this race, and that its north-western peninsulas contain the most typical examples of it In the south-east however another race is found which may be described as yellow-skinned and smooth-haired, and these are clearly Polynesians or "Mahori," that is of the same race as the natives of Samoa and New Zealand In the Fly River and adjacent country both these occur, as well as a mixed race, which D'Albertis seems to think is destined to supplant them. He describes these races as follows —

"The two varieties to which I allude may be defined thus, the yellow, and the black. The term yellow does not exactly express the first, nor does black the second, and those adjectives must be used comparatively only. The characteristics of the yellow variety are as follows:—hair curling or smooth—neither crisp nor woolly, black and shining, often almost of a chestnut hue, forehead large and flat; temples little, if at all depressed; eye orbits scarcely, if at all, prominent; cheek-bones rather high; round chin and round face; large brown eyes, with eyeballs of a bluish-white, the nose often aquiline, never flattened, and generally small, lips moderately full, and brachycephalous and round skull. These people are not prognathous In colour they vary from brown to very light brownish yellow In stature they are not generally inferior to the black race, and their forms are fuller and rounder

"The black variety is distinguished by a narrow and retreating forehead, compressed temples, strongly-marked orbital arches, prominent cheek-bones, aquiline nose, pointed and narrow chin, long face, decidedly prognathous, an oblong skull The eyes are small, either black or brown, the eyeball bloodshot or yellowish, and the men are tall and generally thin The preponderating type exhibits every gradation that can result from these two varieties

"We may therefore conclude that the present inhabitants of Hall Bay (opposite Yule Island) are a mixture of two races, one dark-skinned and crisp-haired, the other with lighter skin and smooth hair, and this is all that can be said from our present knowledge"

The light race—which we may call Papuan Mahoris—are far more civilised than the dark Papuans. D'Albertis says of them:—

"The most perfect harmony seems to reign in families, and rare indeed are cases of quarrel among members of one household. They live in communities, sometimes of more than a thousand inhabitants, in well-built villages,

[1] "New Guinea What I Did and What I Saw" By L M D'Albertis, Officer of the Order of the Crown of Italy, &c, &c In two volumes (London Sampson Low, Marston, Searle and Rivington, 188c) Continued from p 155

worthy to be called small towns, both for their order and cleanliness. They are under the rule of the chiefs or land-owners. The chief is looked upon as father of the family He is called Pacao, and his servant or subject is called Irine. From all I could learn, slavery does not exist, and the sale of human beings is unknown" After describing their daily avocations, amusements, dress, implements, and ornaments (a group of which are figured), he goes on: "Their natural disposition is gentle and placid. They like to spend their time in talking and games, in which men and women take an equal share. Playful and free of speech, they nevertheless do not transgress the bounds of modesty, either in word or deed Women and children are included in every conversation, and often take part in public discussions, which are usually held in the evening. Women are always respected, and in some villages they enjoy a certain supremacy, although the government of the house belongs to the husband. Labour may be said to be fairly divided between the two sexes, and they are accustomed to work from their earliest childhood. . . . The material for civilisation is in them, but will the change make them better? Will they be the happier for

FIG 4—Durabi, a native of Kiwai Island, at the mouth of the Fly River

it? This is a difficult problem, and one which cannot be solved until the experiment has been made. For my part I do not doubt that these, more readily than any other savages whom I know, would answer to the call of a civilised nation which, stretching out a paternal hand, would lead them towards our civilisation! To insure success, however, they should be treated as friends, not as slaves, they should be cherished, not destroyed."

Unfortunately our attempts at civilising savages have as yet in every case failed Are we still, notwithstanding all our wretched failures, to go on in the old way, and allow these interesting and now happy people to be first ruined morally by the teaching of the dregs of our Australian and Pacific traders, and then physically deteriorated by the forced introduction of a form of civilisation utterly unsuited to them? Cannot either philanthropy, or religion, or Government protect these people from all such external influences as have been proved to be unsuited to their condition and stage of development, while aiding them to work out for themselves an indigenous civilisation? Here is perhaps the last chance we have to preserve one remnant of the better class of savages from being crushed under the Juggernaut car of our high-pressure civilisation and mad struggle for wealth.

The inhabitants of the lower part of the Fly River appear to be mostly dark Papuans, while further in the interior a mixed race was met with. Among the curious articles found in this part of the country were numbers of stone clubs, carved into various star-like shapes and forming terrific weapons in close combat. Stone axes are also largely used, closely resembling in form the neolithic celts of Europe.

Maino, chief of Moatta, a village at the mouth of the Fly, was a great friend of D'Albertis', and accompanied him on one of his voyages up the river. An elaborate study, both physical and mental, was made of this savage, and forms one of the best and most valuable passages in the book. A few extracts will show its character. After describing his person, our author goes on:—

"The above is a sketch of the animal Maino. I will now try to draw his portrait as a man, according to the moral sense of that definition. The opinion I have formed of him as a reasonable being is favourable. It is not however necessary to examine him very closely with European lenses, remembering that he is what we call a savage. He has sufficient intelligence for his position, and probably he is not capable of more. . . . He is friendly to the white man because he fears him, and because he knows he can gain by him. He is proud, and takes offence easily, without however showing that he is

FIG 5—Maino, Chief of Moatta

irritated; only once during two months and a half did he display any anger. He is generally silent, and seems meditative. Sometimes he is lively and will laugh, but his laugh appears studied and forced, not natural or spontaneous He is cruel rather from instinct than from education, and in a way that we Europeans can perhaps neither understand nor appreciate justly His cruelty raises him in his own estimation and in that of his dependents—in the eyes of his friends and of his enemies. He considers men and women, if they are strangers to him, good for nothing but to have their heads cut off. Up to the present time his victims number thirty-three. A warrior who bravely attacked him, or a woman sleeping in the forest would be to him exactly the same thing. He would see in each a trophy, a victory; and what he would esteem would be their skulls. He likes to see blood, and it is with marked satisfaction he describes the *modus operandi* in cutting off a head, the instruments used in the operation, and the method of surprising an enemy by treachery, even if a woman or a child. . . . He is tender and affectionate towards his own family, and to his sons at least his temper may be said to be mild. . . . Maino is remarkably selfish. He would willingly let others die of hunger if to relieve them he would have to sacrifice some delicacy intended for himself. I experienced this during the voyage. . . . Notwithstanding certain traits which might make him appear a bad man in the eyes of Euro-

peans, I can testify that Maino is a good fellow, and was a good comrade to us all. His rank and his age prevented his being useful except as a pilot, but in that capacity he was most valuable."

Turning to the lighter race, one of the most interesting and novel facts we find recorded of them is their most ingenious mode of cultivation. Fields were observed in Yule Island so well and evenly tilled that they appeared as if they had been ploughed, but it was afterwards ascertained that all had been done by manual labour.

"The natives form gangs of eight or ten men, each man holding in either hand a very hard wooden pole, sharpened to a point, over six feet long and from an inch to an inch and a half thick. These men stand in a row, and at a given signal plant their rods in the ground, repeating the operation several times until they have penetrated to the required depth, which is generally about a foot. This done, they bear down on the other end of the poles, making them act as levers, and thus loosen a long piece of ground, ten to thirteen yards long, and from a foot to a foot and a half wide; then by alternate heaving up and bearing down, the large mass of earth is upturned, and as they take care to preserve the same measurements and distances, regularity like that of the action of a plough is produced."

On his way home, fresh from New Guinea, Signor D'Albertis suffered partial shipwreck in the Red Sea, and met a number of Somauli men and their families, and was much struck by their resemblance to Papuans. He says: "Who will believe that in these people I seemed to be renewing my acquaintance with the natives of New Guinea, especially those of Torres Straits! Such is the impression they made upon me. I observed the true negro type, which differs from them in several respects, but if several of these natives were transported to New Guinea they might be mistaken for aborigines of that country; those with the receding forehead, aquiline nose, and moderately thick lips—who have curly but not woolly hair. They belong to the type I called Arab when speaking of Moatta and Tawan—the type which, although not predominating, I have often found in New Guinea, and I discover them to-day on the shores of Ras Afun." Our traveller had two true Jamaica negroes with him in New Guinea, and these also closely resembled other types of Papuans, although there were certain minute characteristics of skin and hair by which they could be distinguished. Taken as a whole, and speaking broadly, the Papuan and African races would appear to belong to the same great type of mankind.

FIG 6.—Attacked by Canoes on the Fly River

Our readers will now perceive that, as the journal of an enterprising and observant traveller, Signor D'Albertis' work is one of considerable merit. It is written in a simple unaffected style, and bears internal evidence of accuracy and absence of exaggeration, while it no less clearly shows that in all the best qualities of a traveller its writer has rarely been surpassed.

Living among some of the wildest of savages he overcame them by kindness, courage, and by exciting in them a dread of his vast powers of destruction and command over the forces of nature; and he never took away human life except when attacked by overwhelming forces—when the vessel committed to his charge as well as the lives of its crew were in imminent danger on the Fly River, and even then he beat back his enemies while doing them the smallest possible injury.

Turning now from the general character of the book and of its author, and considering it as an expensive and

somewhat pretentious work brought out by an English publisher, we feel bound to state that it is full of grave defects. This is due probably to the incompetence of the editor, or the total absence of any such necessary functionary; for the original was written in Italian, and we cannot believe that the author himself corrected or supervised the proofs In the first place a considerable number of the illustrations seem to be thrown in at random, and are not referred to at all in the text. Such are the portraits at pp 59, 140, and 151 in vol i. Ornaments and implements from the Fly River are figured in the first instead of in the second volume. A cut of thirty-four separate articles (at vol. i p. 416), though all numbered, has no reference to the numbers; while at vol. ii. p. 136, four elaborate spears or ornamental staves are descri.ed as "Baratus," which are said in the text to be "pieces of armour for war," and to be "worked in very hard stone"!

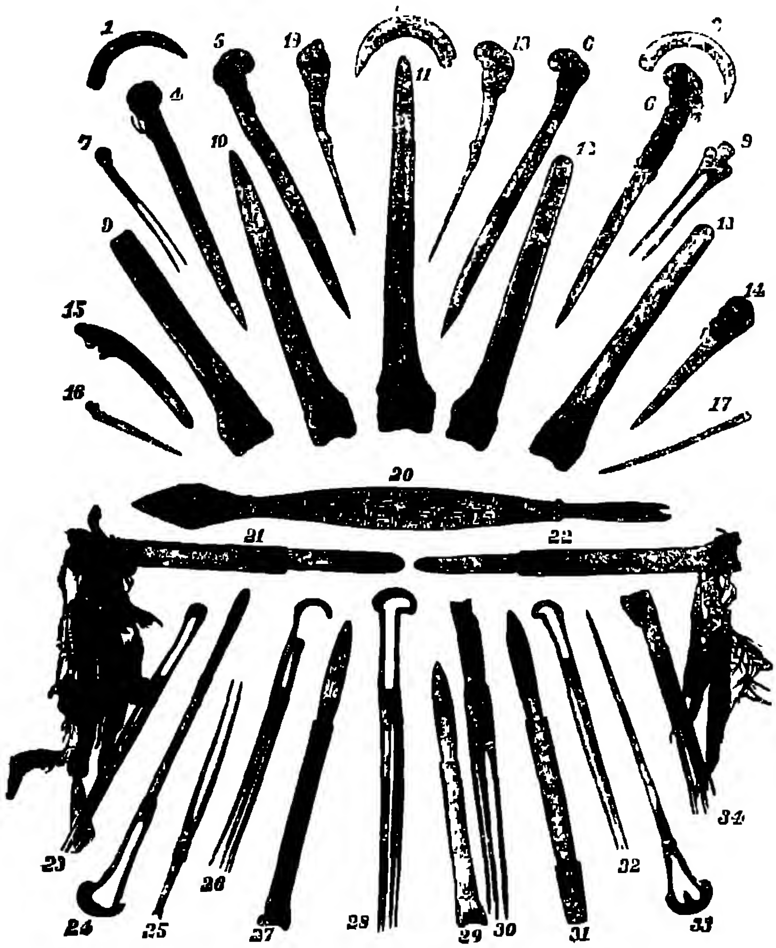

Fig 7.—Implements and Weapons From the Fly River (upper set) and Hall Sound (lower set)

The misprints and misspellings are excessively numerous. At p. 4 we read of "temples excavated in the deserted roads" in Java. At p. 49 the traveller goes to the "source of the river" instead of to its mouth, and at p 222 we have "stone nails" instead, probably, of stone clubs. The names of places and of plants and animals are rarely spelt correctly, and are often spelt differently in adjacent pages. The Italian mode of spelling scientific names has not been altered, and they are often almost unintelligible to an English reader, as *Oloturia* for *Holothuria*, *Stafilinus* for *Staphylinus*, and *Cicas* for *Cycas*. Orankaya (a village chief) is sometimes spelt Orankay and sometimes Oranhay. Waigiou is spelt Waigen, and immediately afterwards Waigeu. Battanta is spelt Battauta, and Daudai is spelt Dandai At the end of the book four vocabularies of native languages are given, but as if to make these of as little use as possible, they consist of four different sets of words, all differently arranged, and none in alphabetical order; so that any comparison with each other or with vocabularies given elsewhere is practically impossible without the preliminary labour of rearranging them Add to this that there is no index to the book and that the only map given is a poor and imperfect one, and it will be seen that the merits of Signor D'Albertis' work have not been enhanced by the manner in which it is presented to the reader

The illustrations on the whole are good, the coloured plate of birds of paradise being excellent But far too many skulls are figured, since these are of no possible interest to the general reader, while, as we have no guarantee for their accuracy, or that they are all figured on exactly the same scale, they will have little value for the man of science.

From the notices scattered through these volumes Signor D'Albertis appears to have made very large collections in natural history, especially of birds, reptiles, and insects It is to be hoped that complete series of these have been kept together, and that, in conjunction with those collected by Dr Beccari, they will be made the subject of some important works. The birds are being carefully elaborated by Prof. Salvadori, but the reptiles and the insects would probably throw even more light on the zoological relations and past history of this wonderful island

Alfred R Wallace

PHYSIOLOGY OF PLANTS

THE two papers [1] which we notice together under the above heading, though relating to different questions in the physiology of plants, have nevertheless something in common Both of them bear on the relationship between the external and internal conditions of life, between external forces, such as light and gravitation, and the constitution of the organism on which these forces act And both tend to show the importance of recognising in plants those specific forms of sensitiveness which may be said to determine the results which will follow external changes

I The behaviour of leaves in relation to light may be illustrated by the cotyledons of a seedling radish; if it is illuminated from above, the cotyledons are extended horizontally, and are thus at right angles to the direction of incident light. If the seedling is then placed at a window, so that it is lighted obliquely from above, and if the stem (hypocotyl) is prevented from bending, the cotyledons will accommodate themselves to the changed conditions by movements in a vertical plane. The cotyledon which points towards the light will sink, while the other will rise, and thus both will become once more at right angles to the incident light.

Two theories have been proposed to account for this

[1] I "The Power possessed by Leaves of placing themselves at right angles to the direction of Incident Light" II "The Theory of the Growth of Cuttings, illustrated by Observations on the Bramble, *Rubus fruticosus*" Read by Francis Darwin before the Linnean Society, December 16, 1880.

property of leaves. the first is that of Frank ("Die naturliche wagerechte Richtung von Pflanzentheilen," 1870), who ascribes to leaves and to some other organs a specific sensitiveness to light called "transversal-heliotropismus" or diaheliotropism ("Power of Movement in Plants," p 438). Just as an ordinary heliotropic organ has an inherent tendency to become parallel to incident light, so a diaheliotropic organ has an inherent tendency to place itself at right angles to the direction of the light The two classes of organs differ from each other exactly as some creeping rhizomes differ from ordinary stems; the rhizome tends to extend itself horizontally under ground, while the stem above the surface grows vertically upwards (see Elfving, in Sachs' "Arbeiten," 1879).

A different theory has been proposed by de Vries (Sachs' "Arbeiten," i 1872), whose views are supported by Sachs ("Arbeiten," ii 1879) with additions or modifications. According to these views it is not necessary to assume the existence of any special kind of heliotropism, since the phenomena might result from the ordinary forms of heliotropism and geotropism acting in concert Thus in the case of the seedling radish illuminated from above, if the cotyledons were apheliotropic (negatively heliotropic) and apogeotropic (negatively geotropic) it is possible that they might be kept in equilibrium by these opposing tendencies. The tendency to move away from a vertical light will make the cotyledons curving downwards towards the earth, and the apogeotropism or tendency to move away from the centre of the earth may exactly balance the downward tendency, so that the cotyledons remain horizontal

Besides the various geotropic and heliotropic tendencies there are other modes of growth which may enter into the combination In some cases there is a natural preponderance of longitudinal tension or growth along the upper surfaces of the petiole, so that owing to impulses arising within the plant there is a tendency for the leaf to curve downwards, or more accurately in the direction in which the morphologically lower side of the petiole is directed, this tendency is called longitudinal epinasty, or simply epinasty, the opposite tendency is called hyponasty. According to the theories of de Vries and Sachs epinasty may be opposed by heliotropism, or by apogeotropism, while hyponasty will of course be opposed by apheliotropism and geotropism, and all these opposing forces may combine in producing an equilibrium The object of the present paper is to test the relative values of the two above described theories that of Frank, and that of de Vries and Sachs.

The method employed was to fix the plants under observation to a horizontal spindle, which was kept in slow rotation by clockwork This instrument (called the klinostat) has been employed by Sachs for the study of ordinary heliotropism, light is admitted parallel to the axis of rotation, and the plants are thus subjected to a constant lateral illumination, while they are freed from the disturbing influence of gravitation, for, owing to their being kept in constant slow rotation, there is no reason why they should bend apogeotropically in one direction more than another (see Sachs in his "Arbeiten," Bd. ii 1879). On the same principle the behaviour of leaves which place themselves at right angles to the incident light has been studied. If a plant with horizontally-extended leaves, which has been illuminated from above, is fixed on a slowly-revolving, horizontal spindle, so that the axis of the plant is parallel both to the axis of rotation and to the direction of incident light, we shall have a means of testing the opposing theories above mentioned.

The plant's leaves will still be illuminated by light striking them at right angles; therefore if Frank's theory is the right one they ought to remain in this position. But if de Vries and Sachs are correct in their views, the leaves ought *not* to be able to remain at right angles to the incident-light, since apogeotropism has disappeared, which was one of the tendencies necessary to keep the leaves in a position of equilibrium.

A considerable number of experiments were made with the celandine, *Ranunculus ficaria*, the results of which are decidedly in favour of Frank's views. The leaves of the celandine are sometimes extremely epinastic, so that they press against the ground, and when a plant is dug up it often happens that, the leaves being released from the resistance of the soil, curve nearly vertically downwards. If such a plant is fixed on the klinostat in the position above described, the leaves will be pointing away from the light, so that if the leaves were apheliotropic, as might be expected according to de Vries' theory, the leaves would remain pointing away from the window But this is not the case, they move forwards until they are approximately at right angles to the light, and then come to rest. Again, if a celandine is placed in the dark its leaves rise up so as to be highly inclined above the horizon, if the plant is then placed on the klinostat the leaves (which now of course point towards the light) again accommodate themselves by curving backwards until they are at right angles to the light. Thus the leaves cannot be called heliotropic or apheliotropic, we are forced to believe that under the stimulus of light they are able to move in either direction, which may be necessary to bring them into the plane at right angles to the light. The other experiments with *R ficaria*, the details of which we omit, lead to the same general result.

Besides a few observations on Vicia, Cucurbita, and Plantago, a series of experiments were made on seedling-cherries, and these lead to a somewhat different result. A cherry-plant illuminated from above has its leaves approximately horizontal, and when placed on the klinostat, as above described, the leaves are unable to remain at right angles to the light, but curve backwards so as to become parallel to the stem of the plant. This movement can be shown to be due to epinasty, not to apheliotropism, and is the result of the loss of balance which follows when apogeotropism is removed. It is clear therefore that the horizontal position of the leaves of seedling-cherries growing normally must largely depend on the balance struck between epinasty and apogeotropism, in accordance with the views of de Vries and Sachs But since these forces obviously cannot produce the power which the cherry possesses, of altering the position of its leaves in accordance with the direction of the light, we must assume that some kind of heliotropism enters into the combination. The view to which the present research lends most probability is that dia-heliotropism (transverse-heliotropism) is the really important influence at work. In the case of the celandine we have seen that the sensitiveness to light is strong enough to determine the position of the leaves—although the natural balance is disturbed by the annihilation of apogeotropism. It seems probable that an essentially similar state of things holds good in the case of the cherry. When the plant is growing normally it trusts to epinasty and apogeotropism to produce an approximate balance, the final result being determined by the stimulus of light. But when the balance is disturbed by placing the plant on the klinostat, the light-stimulus is not strong enough to produce a condition of equilibrium

This view is the same as that given in "The Power of Movements in Plants," and is in accordance with the principle there given. that the chief movements in plants are due to modifications of the circumnutating motion.

II. When a cutting, for instance a piece of a willow-branch, is placed in circumstances favourable for growth, it produces roots at its lower end, while the buds at its upper end grow out into branches. The experiments of Vöchting ("Organbildung im Pflanzenreich," Bonn, 1878) on the growth of cuttings were made by suspending

pieces of stems, branches, &c, in large, darkened jars, the air in which was kept constantly moist by a lining of wet filter paper. The cuttings were suspended both in the normal position—that is with the upper end upwards—and also upside down Vochting found as a general result that there is a strong tendency for the roots to appear at the *basal* end,[1] and the branches to be developed at the *apical* end, whether the cutting had been hung apex upwards or downwards in the glass jar.

Vöchting believes that the growth of roots at the base and of branches at the apex of a cutting are determined chiefly by an innate, inherited, growth-tendency. When the knife divides a branch into two cuttings it separates a mass of identically-constituted cells into two sets, one which form part of the apex of the lower cutting, and another set which form part of the base of the upper cutting And under appropriate circumstances one of these sets of cells might develop into roots, the other into adventitious buds. Vocht holds that it is the morphological positions of these sets of cells (the fact of one being at the base and the other at the apex of a cutting) which chiefly determines the course of their subsequent development. The idea may be expressed somewhat familiarly by saying that each cutting into which a branch is divided is able to distinguish its base from its apex, and can tell where to produce roots and buds, by means of an internal impulse or morphological force which is independent[2] of the external forces, gravitation and light

The theory which Sachs has brought forward in his paper on "Stoff und Form der Pflanzenorgane" ("Arbeiten des bot. Inst Wurzburg," 1880, p. 452) is entirely opposed to that of Vochting. Sachs conceives that Vochting's morphological force is not an innate hereditary impulse, but a tendency produced by the action of external forces during the growth of the formative cells. Thus Sachs believes that the force of gravity acting on the developing cells of an organ produces in it a "predisposition" or enduring impulse which manifests itself in the results which Vochting ascribes to a hereditary force The mode in which Sachs believes gravitation to act is interesting, not only in itself but also as a modification of a theory of Du Hamel's It is assumed that difference of material is a necessary concomitant of difference of form, and that accordingly the materials from which roots are formed are chemically (used in a qualified sense) different from those which supply the branches Sachs' theory supposes that the growth of roots or buds at a given place will be determined by the distribution of the root- and branch-forming materials, and that the distribution of these materials is regulated by the force of gravity. The root-material is in a certain sense geotropic and flows downwards, the branch-material having the opposite tendency. But they are not supposed to be *simply* geotropic, the tendency of the root-material to flow towards the base of a branch is continued after the branch has been made into a cutting and hung upside down, so that the root-material flows upwards towards the base of the cutting, because that end was originally downwards, and *vice versâ* with regard to the branch-forming matter.

The observations on the bramble, which form the subject of the present paper, were carried out with the object of deciding how far the natural growth of roots in the bramble agrees with Vochting's or Sachs' theories on the growth of cuttings.

The long sterile shoots of the bramble are well known to possess the power of rooting at their ends. The terminal bud is thus protected during the winter, and the store of nutriment contained in the club-like thickened end of the branch forms a starting-point for new growth in the spring. It is commonly the long pendant branches growing vertically downwards which reach the ground and form roots It might therefore be supposed that gravitation determines the growth of roots at the *lower* end of the branch, just as in a cutting made from an erect willow branch the roots grow at what was originally the lower end But observations made on brambles under certain circumstances show that this is not the case When brambles grow on a steep bank the majority of the branches grow down hill at once, or else straggle more or less horizontally along the bank and finally turn downwards. But a certain number of branches grow uphill, and some of these take root at the apex. When therefore we find on the same individual plant some branches forming roots at the physically lower, and others at the upper end, we may feel sure that the distribution of root growth in the bramble is not determined by gravitation We mus believe that there is a morphologically directed impulse which tends to the production of roots at the apex of the branch, whether the direction of its growth has been upwards or downwards It is true that in the observed cases the extreme end of the branches was bent so that from 1 to 9 inches was inclined at from 2° or 3° to 5° below the horizon, but it can hardly be imagined that this fact influences the growth of roots at the apex; and experiment shows that it is not necessary that even a single inch should be inclined below the horizon. A bramble branch was tied, apex upwards, to a vertical stick, and was surrounded by damp moss and covered with waterproof cloth, under these circumstances a plentiful crop of roots sprang from the terminal part of the branch This result combined with the observations made with brambles growing on a steep bank seem to show that an internal impulse or morphological force regulates the growth of roots in the bramble.

When a cutting is made from a bramble the only development that takes place is the growth of the axillary buds at the apical end of the cutting. Under certain circumstances these side shoots take on a root-bearing function They are stunted in growth, being, it may be, 10-12 mm in length and 3 or 4 mm or more in breadth; they assume a peculiar club-like form, being thicker at the apex than at the base, and are clothed with rudimentary scale-like leaves, from among which a number of relatively large roots spring forth

In order to determine whether the production of this root-bearing type of root is determined by gravitation or by a "morphological force," cuttings were made from branches whose direction of growth was above the horizon. Such cuttings were hung apex upwards, and it was found that the most apical buds were capable of developing under these circumstances into the root-bearing type of branch Similar rooting side-shoots are produced by cuttings made from branches which have grown beneath the horizon, it is therefore clear that gravitation is not the chief[1] determining force in this form of root production

When the end of a branch is injured, which often occurs when a bramble grows along the ground near a pathway, the most apical bud or buds grow out into branches; these may be ordinary branches which ultimately take root. Under certain circumstances, the stunted club-shaped root-bearing side-shoots may be developed whose whole formation is devoted to the bearing of roots. It is therefore clear that the production of such rooting shoots in cuttings is the same process that occurs in branches injured in a state of nature; a process which enables the branch to perform the function, the normal performance of which had been interfered with. And this fact enables us to see in what way a

[1] The basal end is that end of a cutting nearest to the parent plant, the apical, is the opposite end

[2] Vöchting states distinctly that gravitation and light do affect the positions in which organs are developed in cuttings, but he considers the internal impulse as the stronger determining cause

[1] The experiments seem to show that gravitation has *some* influence on the growth of roots in the bramble

morphological growth-impulse is better fitted for the requirements of the case than any possible dependence on gravitation as a guiding force. When the end of a branch is injured it is clear that if a side-shoot is to be developed to carry on the function of the injured apex, it will have the best chance of success if it starts from the position which the end of the original branch had already gained before it was injured. Therefore the bud which is nearest to the injured apex will be the most suitable one to be developed into a new branch And thus it is advantageous to the plant that the place where the new development is to take place should be determined morphologically, not by gravitation

Thus in the bramble the behaviour of cuttings is a repetition (cf Vöchting, "Organbildung," p 107) of the normal process of restoration of a deranged function in the plant, how far this is the case with other plants must remain at present undetermined

NOTES

WE are very glad to hear that Bedford College is taking a leading part in giving to women the opportunity of studying thoroughly physical science It has this session opened a physical laboratory, under the able direction of Dr Lodge A chemical laboratory was added to the College some years ago, and has proved of great service to the students, several of whom have passed the science examination of the University of London.

THE death is announced of M Lécard, a promising French botanist, as the result of excessive fatigues during his late journey in Soudan. M Lécard was formerly director of the Public Botanical Gardens at Saigon, in Cochin-China, and at Richard Toll in the colony of Senegal During the past year he was intrusted by the French Minister of Public Instruction with the important mission of studying the flora of the Upper Niger, a question now of no slight interest in view of the probable construction of the Trans-Saharan Railway. Various difficulties prevented his reaching the Niger At Koundiam, however, the most distant point reached in his journey, where he was forced to pass the rainy season, he made the valuable discovery of five varieties of annual vines, the fruits of which so closely resemble our ordinary grapes that he regarded them as fully able to replace the grape in the production of raisins and wine. M. Lécard hoped also to find in his new discovery the means of satisfactorily combating the phylloxera, and inspired with this desire, sought to make extensive collections of the seeds of the vines to bring back to France M. Lécard, in a letter recently read by Dumas before the French Academy of Sciences, expressed the fear of having lost his health by the privations incident to this journey—a prevision unfortunately too completely realised.

THE death is reported of Dr. Wilhelm Heintz, Professor of Chemistry at Halle University, at the age of sixty three years.

THE death has taken place, on the 16th inst, at the age of ninety-one years, of Mdlle. de Montgolfier, daughter of Etienne de Montgolfier, the inventor of the balloon to which his name is attached.

PROF. WILLIAMSON, Graham's successor in the Chair of Chemistry at University College, London, has complied with the request of the committee of the Chemical Section of the Philosophical Society of Glasgow that he should act as adjudicator in the competition for the Graham Medal.

PROF. TYNDALL, Prof. Haeckel, and Dr. Andrew Buchanan have been elected Honorary Members of the Philosophical Society of Glasgow.

AMONG the buildings which are to be erected on the new Observatory grounds in Paris when legally handed over to Admiral Mouchez will be the great dome for the large refracting telescope which is now building This dome will measure twenty metres in diameter, and its weight will exceed sixty tons.

THE credit of 300,000 francs asked by M Cochéry for the forthcoming Exhibition of Electricity and Congress of Electricians at Paris has been voted by the Chamber of Deputies unanimously. The Bill has been sent to the Senate, which will probably have passed it by the time this number is published.

ON December 12 took place at the Sorbonne the celebration of the fiftieth anniversary of the foundation of the Polytechnic Association for delivering scientific lectures all over France. This Society was established a few months after the Revolution of July, 1830, by a certain number of pupils of this celebrated school. The principal address was given by M Gambetta, who praised science in magnificent style. M Gambetta declared his conviction that Auguste Comte was the profoundest thinker of the whole century

FREQUENT observations on the retrograde motion of glaciers have been made of late years. One of the most assiduous of observers is Herr W Gromer, proprietor of the Hotel on the Schafberg He reports that during September the retrograde motion was exceptionally large, larger indeed than he had ever seen during seventeen years. The Gosau glacier (Dachstein), the Hochalmspitze, and the Uebergossene Alp showed hardly any ice at all on September 12 last, so that with the telescope only *débris* of rocks could be seen. Herr Gromer ascribes this phenomenon to the unusually high temperature which reigned upon the Alps during last winter, as well as to the constant rain during the summer

WE are glad to receive a third edition of vol I. of Harcourt and Madan's "Exercises in Practical Chemistry" (the Clarendon Press). Mr. Madan is the sole reviser of this edition, and we quote with approval the following passage from his preface — "Practical chemistry seems in danger of being made far too much a study of a few reactions of salts, got up for the purpose of detecting them in the course of an analysis. This is of course due to the requirements of examiners, to satisfy which nearly all the very moderate time available for practical instruction in schools must at the present day be spent. Moreover analytical work (in the narrow, technical sense) entails, like Latin verses, less trouble to the teacher and less risk to the pupil than other kinds of practical work, while it undoubtedly affords, when intelligently used, a very excellent training in the application of logical methods But it may well be doubted whether a more real and valuable advance in a scientific education is not made by the careful preparation and examination of the properties of such a substance as oxygen, or by an exact study of a few examples of oxidation and reduction, than by simply observing, for instance, that chlorides give a white precipitate with silver nitrate which is soluble in ammonia."

MR. C SCHOESSTER, one of the Commissioners at the Melbourne Exhibition, we learn from the *Colonies and India*, has been visiting the Geelong vineyards, and reports that they are suffering from *Phylloxera* in the worst form, and ought to be totally destroyed.

PROF. DEWAR will give the first of his Christmas Lectures (adapted to a juvenile audience) on Atoms, at the Royal Institution on Tuesday next, December 28, at three o'clock

A BOTANICAL society for Northern Thuringia has been founded at Sondershausen by Prof Leimbach The new Society takes the title of "Irmischia," in memory of the celebrated botanist Irmisch, who died at Sondershausen last year. The immediate object of the Society, which has already a good

number of members, is the minute investigation of the Thuringian flora, and the making of botanical collections.

A GENERAL meeting of the Mineralogical Society of Great Britain and Ireland will be held at the Museum of Practical Geology, Jermyn Street, to day, at 8 p m. The following papers will be read.—"On Tyreeite," by Prof. M F Heddle, F R.S.E., "On Minerals New to Britain," by Prof. M. F. Heddle, F.R S.E., "Note on Gilbertite," by J H. Collins, F G.S, "On Brochantite," by Wm Semmons, "On a Remarkably Fine Crystal of Euclase," by M. Guyot, "On the Action of Organic Acids on Minerals," by Prof. H. C Bolton, communicated by J. H. Collins; "On Strontium from Westphalia," by Joseph J Acworth, F.C S, communicated by F. W. Rudler, F.G.S.

UNDER the common name of "Guaco" many plants are known belonging to different natural families, which have a reputation for curing snake-bites. In a recent number of the *Pharmaceutical Journal* particular attention is drawn to one of these guaco-yielding plants, the *Mikania guaco*, a composite plant of South America. The paper referred to is the substance of a letter received at the Royal Gardens, Kew, from a correspondent at La Salada, New Grenada, in which the writer gives his personal testimony as to the value of the remedy, and says that it forms the basis of all the preparations of the snake bite doctors of the district Notwithstanding that there are several species of snakes in the country whose bite is considered mortal, some killing in a very few hours, it is asserted by the writer of the letter, who has resided in snake-infested regions for many years, that properly and promptly administered the guaco is a sure cure for the bite of the most venomous An infusion or tincture of the leaves is used internally, and hot poultices of the bruised leaves and stem are applied externally.

THE Report on the Botanic Gardens, Georgetown, Demarara, for the half-year ending June 30 last has just been received. Its matter is mostly of local interest We note however that Mr. Jenman, the superintendent, refers in one part of the Report to the rapid growth of some introduced plants. "This," he says, "is more particularly shown by the roses obtained from England The hybrid perpetuals from average-sized nursery plants have in the three months which have elapsed since they were put out, grown into bushes from six to seven feet high, and the other hard-wooded things have hardly done less well, while herbaceous plants such as *Coleus*, *Alternanthera*, *Iresine*, *Amaranthus*, &c, appear to rush up to maturity in two or three weeks. Much of this luxuriance is due however to the very moist season experienced, as vegetation soon suffers and becomes stagnant with even a short period of drought in the stiff, tenacious soil of the coast land of the colony."

A PLANT recently introduced to Queensland by accident is reported to be giving some trouble in the colony in consequence of its poisonous effects upon cattle. The plant is *Xanthium strumarium*, and it is said to have been introduced along with cotton seed From experiments made with the plant by administration of the extract to some animals it seems at first that no particular symptoms were apparent, but after a period of about half an hour the animal becomes torpid and unwilling to move about. "The torpidity gradually increases, and without notable struggling or excitement the breathing ceases, after which the heart's action becomes feeble and stops. In weaker doses recovery of the functions of life takes place, and the animal appears little the worse for the experiment. The animals poisoned retained their intelligence to the last. An extract prepared from the common Bathurst Burr, *Xanthium spinosum*, gave similar results, though the stubborn character of this plant does not offer a tempting food for cattle, and they are not therefore poisoned by it." Both species are found as casual weeds in this country, though they are not considered to be indigenous.

ON the 7th inst. the distinguished Vienna anatomist, Dr. Hyrtl, reached his seventieth birthday He received numerous addresses from medical bodies in Austria, and congratulatory telegrams from all parts of the world.

IN Banjaluka (Bosnia) a distinct shock of earthquake was felt on the 6th inst. at 9 18 p m, direction north-east to south-west, duration four seconds. In Agram, on the 11th, a violent shock was experienced about 5 a m, and one less violent about 7 14 a.m. Since the 12th there have been no shocks there. The entire number of shocks at Agram during the earthquake period—November 9 to December 10—is (according to official data) fifty-nine. In Gurkfeld (Styria) shocks of brief duration were felt on the 11th inst. at 5 and 7 12 a m., direction south-east to north-west.

A SLIGHT shock of earthquake was felt at Charleville, Ireland, on Saturday morning It passed from the north-west to the south-east, and lasted for five seconds

THE new "Year-book of Photography" contains a nice portrait of Daguerre, the father of photography, from a daguerrotype taken in 1846 by Mr. J. E Mayall.

IN a moor of the Canton of Vaud (Switzerland) a well-preserved boat, dating from the age of pile-dwellings, has been found. It measures eleven metres in length and one metre in breadth, and has been conveyed to Lausanne.

THE ruins of a once magnificent bathing establishment have been recently discovered by Prof Giuseppe Novi not far from Herculaneum They are covered with a layer of ashes and lava of ten metres thickness. What has been brought to light up to the present is said to eclipse all previous discoveries of a similar nature both in Herculaneum and Pompeii The fountains and tanks of these "Terme" are made of oriental granite and adorned with sculptures The floors are of coloured glass mosaic; unfortunately it is but badly preserved. The walls of the various buildings are elegantly ornamented with paintings and stucco-work The excavations are to be continued

OUR ASTRONOMICAL COLUMN

SWIFT'S COMET —The evidence in favour of a period of about 5½ years instead of about 11 years for this comet is apparently strengthened by an able note from Mr. S C. Chandler, jun., which we find in an advance number of the Boston *Science Observer*. He brings the two periods to bear upon the representation of the observations of 1869. Starting with Prof Bruhns' parabolic elements in *Ast. Nach* No. 1788, he computed an ephemeris and compared therewith all the published observations, thirty-five in number, after taking into account parallax and aberration. The residuals were found to be considerable and systematic, and with the view to obtaining a nearer approximation to the orbit before proceeding with the determination of final elements, he formed three normals, using for the first all the observed places, six in number, from November 29 to December 1 inclusive; for the second all the places from December 8 to 10 inclusive, eleven in number, and for the third six observations between December 26 and 31: these observations were made at Hamburg, Konigsberg, Kremsmunster, Leipsic, Manheim, and Vienna; he thus gets for the foundation of his subsequent work the following normal positions:—

Washington M T	App R.A. h m. s	App. Decl ° ′ ″
1869, November 29 82475 ..	23 1 5·20 .	+ 15 51 57 7
December 8 81453 ..	0 3 37·28 ..	20 55 2·1
December 29·43628 .	2 39 22·08 ..	+ 26 30 56·8

From these data Mr Chandler calculates elements upon three different hypotheses: (1) that the orbit is a parabola; (2) that it is an ellipse with a period of 4006 days, or about 11 years (3) that it is an ellipse with a period of 2003 days, or about 5½

years, and he finds from these three orbits the following residual errors for the second normal place :—

	Longitude.	Latitude
	"	"
Parabola ..	− 3·1 ..	+ 25·7
11-year ellipse	− 0·6	+ 12·9
5½-year ellipse .	− 0·3 .	+ 4·1

Mr. Chandler finds that an attempt to reduce these errors in latitude on the assumption of a parabolic orbit or an elliptic orbit of 11 years' period, will only lead to intolerable discordances in the longitudes, and he considers that for both these hypotheses the residuals are far in excess of the probable error of the normal position. For the shorter period, on the contrary, the residuals seem well within reasonable limits of error, and his conclusion therefore is that the comet will be found to revolve in about 5½ years His ellipse with this assumed period is as follows, and will be found in close agreement with that obtained on a similar hypothesis from the observations of the present year, by MM Schulhof and Bossert, which we gave last week :—

Perihelion passage, 1869, November 18 59702 Washington M.T

	° ′ ″	
Longitude of perihelion .	42 58 53	M. Eq
,, ascending node	296 46 2	1869·0
Inclination	5 23 44	
Excentricity .	0 6581359	
Semi-axis major	3·10971	
Log. perihelion distance	0 0265728	

It appears that the comet was observed at Harvard College until January 3, 1870, or three days later than at any other observatory, and Prof Pickering has had these late observations very carefully reduced.

At the actual appearance a communication from Mr. Lewis Boss, Director of the Dudley Observatory at Albany, N Y, shows that the comet was micrometrically referred to a star, with the 13-inch refractor of that establishment, on the evening of October 11, but the declination of the comparison-star (B D. + 17°·4611) needs further examination, it might be referred to Bessel's star 385 following and about 6½′ north If good observations can be obtained towards the end of the present month the elliptic orbit may admit of pretty close determination from the observations of 1880 alone. The following ephemeris is calculated from MM. Schulhof and Bossert's ellipse of 5½ years .—

At Greenwich midnight

A New Comet —A small, pretty bright comet was discovered by Dr Pechule at Copenhagen on the evening of December 16, in R.A. 18h. 49m., Decl. + 10° 30′. Daily motion, + 5m. and + 40′.

Occultation (?) of 73 Piscium by Jupiter.—On February 3, 1881, according to Leverrier's Tables of the planet Jupiter and the position of the star 73 Piscium (rated 6 om. in the *Durchmusterung*) brought up from the Greenwich Catalogue of 1872, the star should be occulted by the planet about 2h 8m G.M.T. Very small change however in the place or semi-diameter of the planet, might suffice to bring about merely an appulse. The facts of the case may be well ascertained in easterly longitudes, as at Madras, where the conjunction in Right Ascension appears to occur when the planet is 3h. 26m. past the meridian, about 7h 29m. mean time. The apparent place of the star on February 3 is in R.A. 0h. 58m. 43·53s., Decl. + 5° 1′ 10″·2. The polar semi-diameter of the planet, according to the value of mean semi-diameter now adopted in the *Nautical Almanac*, will be 17″ 2, and allowing for parallax, this seems to place the star a little over 2″ within the planet's northern limb.

METEOROLOGICAL NOTES

From an able and temperately-worded article in the New York *Nation* on the Signal Service Succession, it is plain that meteorology is in a critical position in the United States at the present moment The whole question of the future of meteorology in that country practically turns on the sort of man who is to be appointed to succeed the late lamented Gen Myer As regards the bearing of the question on the promotion of the great financial, commercial, and educational concerns of the country, the writer of the article well puts it when he states that "it depends altogether on the future management of the office whether its activity shall be confined to a lifeless routine without any attempt to make new discoveries or introduce improved methods, or whether it shall be animated by that progressive spirit which will not be satisfied until every man within reach can be informed of coming meteorological changes as long in advance as it is possible for them to be foreseen" To accomplish this end much more is needed than a most diligent discharge of the daily duties of the office, such as will put the public in possession of forecasts drawn up on the lines that have hitherto been followed in forecasting the weather It was an essential feature of General Myer's procedure that in framing the forecasts in the office he confined himself simply to making the best use of what was already known of meteorology But whilst this continued the practice of his office, he had the genius to see that if the system of forecasting weather is to make way it is absolutely indispensable to strike out entirely new lines of observation with the view of arriving at some positive knowledge of the great movements of the atmosphere and their determining causes. Hence his great scheme of International Meteorology, by which was secured one daily observation at the same physical instant, where possible, over the globe, and the regular publication of the monthly results in the U S Weather Maps, with which our readers are familiar. These admirable maps, together with the Weather Maps of the States themselves, published at intervals of eight hours through a period of ten years, now furnish a mass of material the value of which it is not possible to overestimate, and the adequate discussion of which, it may be very safely said, is the next great step to be taken by meteorology This step it is in the power of the United States to take, and whether it be taken or not depends almost wholly on the character of the man who may be called to fill the place so suddenly left vacant by General Myer's premature decease What, above all, is imperatively required, is a sympathy with science and workers in science, so strong and so decided that he will, without fail, enlist in the service of his country some of the best intellects who will give their time and their energies to work out the great problem of weather prognosis

The American mails inform us that a frost of unusual severity for the season set in over Canada and the middle States on November 19. It came so suddenly and with such intensity that vessels of every description were frozen up and fixed, in many cases in mid-stream The cold was greatest all along the St. Lawrence, where the thermometer ranged from zero to − 10° 0. Several ocean steamers, even, were placed in a very precarious position, and altogether it is estimated that 800 vessels laden with grain, potatoes, fruit, and other produce were frozen up, and many deaths have occurred in consequence of the frost So early and intense a frost has not been experienced in Canada since 1873 Closely following it occurred a remarkable depression of temperature in the British Islands, which as regards certain districts in North Britain was unprecedented at so early a period in the winter months. It was an accompaniment of a wide-spread area of high pressure which appeared off the north-west of Scotland on the 20th as shown by the English and German daily weather maps. On this day temperatures fell low for the season, particularly along the west from Cornwall to Shetland. On the 21st the high-pressure area had advanced a considerable way towards the south east, and under the clear skies and light winds which characterised it, the temperature fell in many places in Scotland to a degree which would have been noteworthy in the depth of winter. The protected thermometer fell at Aboyne Castle on Deeside to zero, and to 1° 0 at several places, viz., at Lanark in Clydesdale, at Stobo Castle near the head of the Tweed, and at Thirlestane Castle on the Leader. These low temperatures were approximated to at a considerable number of the other stations of the Scottish Meteorological Society situated in the larger valleys in in-

land situations. As on similar occasions, the influence of the sea in arresting the fall of temperature was strikingly seen. Thus the minimum temperatures on the 21st were 31°·7 at Portpatrick, 8°·3 at Drumlanrig Castle on the Nith, 1°·0 at Stobo Castle and Thirlestane Castle, 11°·7 at Milne Graden near Coldstream, and 17°·7 at Eyemouth on the East Coast. At Douglas Castle and Thirlestane Castle the unprotected thermometer fell to −6°·0.

MR. H. S EATON has rendered a great service to meteorology by a paper on the average height of the barometer in London, which has just appeared in the *Journal* of the Meteorological Society for October. The great value of the paper consists not so much in the long period of 100 years for which the monthly averages of each year are given, as in this, combined with a careful and laborious elimination of instrumental errors and errors arising from breaks of one or more days in the observations of the months. The series is sufficiently extended as to entitle it to be considered one of the most valuable we possess in dealing with questions of secular meteorological variations. The mean atmospheric pressure at 32° and sea-level for London is 29·952 inches, the mean monthly maximum 29 996 inches occurring in June, and the minimum 29 900 inches in November, the mean for October being nearly as low, viz., 29 909 inches. In a discussion which followed the reading of the paper Mr Strachan remarked that even another 100 years' observations would not alter the positions of these points of the London curve—a remark no doubt quite true for London On advancing however to the south-west the means for June and July approach towards equality, and ultimately the July mean becomes the larger as we advance into the region of high pressure which occupies the Atlantic to the south-west during this month On the other hand, as we proceed northward, the means for May and June approach towards equality till about the south of Scotland the mean for May becomes the maximum for the year, and the further north the more decidedly is May the maximum, till in Iceland it exceeds the mean of any other month by the tenth of an inch. Attention was drawn to the dips in the curve of pressure for April and July. These in all probability are permanent features in the London curve of pressure for March-April and July when drawn from a long average, since the former is connected with the east winds of spring and the latter with the great summer barometric depression which falls to the lowest point in July in the interior of the Europeo-Asiatic continent.

IN the same number Mr. Marriott gives a brief *résumé* of three years' observations made by Mr. F. E. Cobb at Stanley, in the Falkland Islands, which, from the geographical position of the place, possess some interest The results show a mean annual pressure of 29 604 inches, the maximum occurring in winter, and the minimum in summer. A singular feature of the monthly means is their comparative steadiness from year to year, the highest being 29 819 inches for August 1876, and the lowest 29·342 inches for February of the same year The difference of these two extremes is only 0·477 inch. It would be difficult to select from Mr. Eaton's 100 years mean pressures for London any consecutive three years which would show so small a variation between their two extreme monthly means as do these Falkland Islands' observations The prominent features of pressure in those islands would appear to be its variability, the constant recurrence of rapid changes, and the comparative absence of protracted periods of very low, but especially very high pressures—occasioned in all likelihood by there being no great mass of land in that quarter of the globe. A like equableness from year to year characterises the temperature and rainfall of the climate. The rainfall is surprisingly small, amounting only to twenty inches in the year; but the falls, though not heavy, are frequent, there being 236 rainy days in the year. The lowest mean temperature of any of the thirty-six months was 35°·4, and the highest 52°·6. The climate is eminently a dripping one, and when the range of its temperature is taken into consideration, and its high winds, it is one of the most disagreeable climates of the globe.

GEOLOGICAL NOTES

NAINI TAL LANDSLIP.—In NATURE, vol. xxii. p. 505, attention was directed to landslips in connection with the catastrophe at Naini Tal on September 18. We have just received part 4 of vol. xiii. of the *Records* of the Geological Survey of India, containing a paper by Mr. R. D. Oldham, of the staff of that Survey, who was deputed to examine and report on the landslip to the Director. From this paper and a note appended to it by Mr. Medlicott, it appears that we were in error in supposing Naini Tal to stand upon Tertiary rocks. It lies just to the north of the younger formations, and is situated upon "more or less imperfectly-cleaved clay slates." These rocks are subject to a decomposition which penetrates deep into their mass, and it would seem to have been the cover of loose, decomposed detritus which, thoroughly saturated with water from the heavy rains, slid down the hill, and gave rise to the catastrophe.

THE "CHALLENGER" WORK —Steady progress is being made in the investigation of the deep-sea deposits dredged up by the *Challenger* Expedition. M. Renard has established himself at Edinburgh, where, in concert with Mr. J. Murray, he is busily engaged in subjecting the various dredgings to chemical and microscopic analysis. In the first volume, devoted to an account of the bottom of the ocean, will be gathered together the facts amassed during this laborious study. It will avoid all speculation, but will contain such a body of data for the explication of the sedimentation and chemistry of the ocean abysses as has never before been available In a subsequent volume the authors will develop the views to which their prolonged and minute investigations have led them No part of the work of the *Challenger* promises to possess a profounder interest in geology.

GEOLOGICAL SURVEY OF BELGIUM —The dual organisation for the Geological Map of Belgium is likely to lead to some curious reduplications and complications Besides the staff under the direction of M Dupont, there are other geologists independently at work under the Ministry of the Interior who are determined to lose no time in bringing out sheet after sheet of the geological map as surveyed by them. In particular the Baron O Van Ertborn and M Paul Cogels have been eminently energetic. The Baron made a convention with the Ministry towards the end of last year to complete six sheets with their explanatory texts before June 1 of the present year. He has been able to keep his engagement except as regards the Lubbeek sheet, for which he obtained a delay until the close of this year We have just received the Boischot and d'Aerschot sheets Meanwhile M Dupont makes no sign. Specimens of his map were seen at the Paris Exhibition in 1878, and also at the Dublin meeting of the British Association last year But so far as we are aware, nothing has yet been issued The Director is understood to be resolved to make his map the most perfect geological map that has ever been published. It is being chromolithographed at Leipzig. Considerable interest is naturally felt among geologists to see the first completed specimens of this long-expected work. We are curious also to know what will happen when the Official Survey and the free-lances meet on the same ground Will the Government publish two different geological maps? The position reminds us of that which roused the activity of the Congress of the United States a few years ago, when it was discovered that the same Territory in the far West was sometimes independently surveyed by two or three different organisations, all paid out of the public purse. Only in Belgium things are worse, for the country is small, and the certainty of reduplication must have been foreseen from the beginning.

GEOGRAPHICAL NOTES

AT the meeting of the French Geographical Society on November 19, M. Henri Duveyrier read an important memorandum which he had drawn up on the subject of the sources of the Niger. After going carefully into the question of Major Laing's prior discovery and various matters relating to the hydrographic system of the Niger basin, he thinks it very doubtful if any other stream will ever be discovered having a right to be deemed the chief source of the river, than the Tembi-Kundu visited by MM. Zweifel and Moustier. M Duveyrier's remarks will no doubt be published in an early number of the French Geographical Society's *Bulletin*, and it may be hoped that it will be illustrated by a large scale map. At the annual meeting of the Society last Friday, M. Maunoir read his usual report on the work of the Society and the progress of geographical knowledge. It was announced that the Society had now about 2100 members, being an increase of about 100 in the year.

HEFT 3 of vol. ii. of the *Mittheilungen* of the German African Society contains a brief report of the work of the year. The

most striking feature of the work is the successful journey of Dr. Lenz from Morocco to Timbuctoo and thence to St. Louis in Senegal. In the region to the south of the Congo some good work has been done. Dr. Buchner has probably got beyond the district known as the kingdom of Muata Yanvo, while Major von Mechow has reached the Coango from Malange by following down the valley of the Cambo, a tributary of that river. The navigation above the junction is obstructed by cataracts, but Major von Mechow did not expect to meet with any difficulty in sailing down the Coango to its mouth in the Congo. Dr. Pogge is on his way out to Portuguese West Africa to proceed to the interior to found a station at Mussumba, the chief town in Muata Yanvo's kingdom. Herr Flegel has been exploring the Niger in the *Henry Venn*, and expects shortly to reach Sokoto. Dr. J. Hann has a paper in this number on the meteorological and hypsometrical results of Rholfs' expedition to the Kufra Oasis. The Society have received instructions from the Imperial Government regarding the manner in which the 3750*l.* granted by the Reichstag is to be divided. Dr. Gerhard Rohlfs' expedition to Abyssinia will receive 1600*l.*, and 150*l.* is to form a reserve fund for this same undertaking. The expedition now being organised at Zanzibar under the leadership of Herr von Scholer will receive 800*l.*, and the remaining 1200*l.* are for Dr. Pogge, who is attempting to reach the capital of Muata Yanoo, in Central Africa, in order to found a station there. The Society has also granted 250*l.* to Herr R. E. Flegel, who ascended the Binue River this year.

THE new number (No. 9 of vol. vii.) of the *Verhandlungen* of the Berlin Geographical Society contains papers by Herr Gustav Niederlein on some of the scientific results of an Argentine expedition to the Rio Negro in Patagonia, and by Dr. Nachtigal on the ethnological place of the Tubu and Kanuri.

THE December number of *Petermann's Mittheilungen* contains an interesting paper by Dr. Rholfs on the Libyan Desert, in which he shows that it is the eastern part of the Sahara, and not the western, that is the real desert, broken only here and there by oases. Indeed the extreme west of the Sahara, for a distance of from 400 to 500 kilometres from the coast, does not strictly belong to the desert at all, and even the eastern half, the more we know of it, the more numerous are its oases found to be. There is an eclectic article on the Liu-Kiu Islands, by Dr. v. Kloden, a paper on the New Volcano on Lake Ilopango, and a map of the South Coast of Franz Josef Land, based on Mr. Leigh Smith's recent discoveries. In the *Monatsbericht* some interesting details are given of Dr. Junker's journey to and his sojourn in the Niam-Niam country. A letter from Dr. Emin Bey, the Governor of the Egyptian Equatorial Province, informs us that Mtesa, King of Uganda, whom Mr. Stanley so whitewashed, is as tyrannical and bloodthirsty as ever, and does not intend to be either Christianised or Mohammedanised, but to adhere to the ways of his forefathers. Dr. Emin is anxious that explorers should turn their attention to the Equatorial Province, which forms a splendid field for botanists, zoologists, and other specialists.

NOTWITHSTANDING the belief in some quarters that the American Arctic steamer *Jeannette* has been lost with all hands, it is thought in San Francisco that Capt. De Long and his staff and crew may have only abandoned her, and be waiting succour at some point. An attempt is therefore being made to get a small schooner sent out next spring to search Wrangell Land.

EARLY in the present year Mr. W. H. Cornish, of the Surveyor-General's Department at Adelaide, was engaged for some two months in examining the country in the far interior for the extension of the trigonometrical survey and traverse of the Herbert River. In about lat. 30° 59′ near that river he crossed a piece of country which by his account almost baffles description; it was flood country of the Herbert, and was completely rotten. "Cracked ground," he reports, as a term is scarcely applicable, for there were yawning chasms from four to five feet deep, and even deeper, and eight to twelve inches wide at every few feet. The country indeed was so bad that it took the camels six hours to travel seven miles, and Mr. Cornish's difficulties were increased by the unusually intense heat of the weather. Mr. Cornish believes that before long the cattle-trade from the part of Queensland which he visited will go southwards to Australia as soon as the settlers who are beginning to open up the country on the Herbert, Diamantina, and Mulligan become sufficiently acquainted with the means of communication. During his journey Mr. Cornish did not see more than 300 natives, who were all friendly, but he believes there are large numbers in the region he travelled through, and that it would not be prudent to trust them.

DR. LAWS, the head of the Livingstonia station on Lake Nyassa, is actively engaged on linguistic work. He has translated various portions of the New Testament into Chinyanja, and the Laing trustees have agreed to publish his translation of St. Mark's Gospel. Dr. Laws has also begun the Yahitonga language spoken at Bandawi, and he has collected a short vocabulary of the Chungu dialect at the north end of the lake. The Livingstonia and Foreign Missions Committee of the Free Church of Scotland have recently agreed that, on the assurance that there will be no difficulty there as to civil government, owing to the presence of powerful chiefs, Bandawi shall be made the principal port of the mission on Lake Nyassa, while sanitary out-stations are to be sought on the neighbouring hills among the Angoni. As soon as possible however the east side of the lake is to be explored, in the hope of finding a better sanitarium on the so-called Livingstone Mountains.

MESSRS. GRIFFITH AND HUTLEY, who lately established the first mission station on the west side of Lake Tanganyika at Mtowa, near the mouth of the Lukuga Creek, have sent home to the London Missionary Society some information respecting the religious notions of the Waguha. There appears to be a marked difference on this point between the tribes on the opposite shores of the lake. Those on the east side have no images or idols, but on the west shore they have them in great numbers, and have certain beliefs connected with them. Mr. Griffith observes that the first thing which strikes the African traveller on entering the western half of the continent is an image at the entrance of every village, besides many others inside it. The image is in imitation of the human figure, and is called *Mkisi*, which is the same as the Mzimu of the Swahili, and means spirit.

THE new *Bulletin* of the Belgian Geographical Society contains reports relating to the International African Association's expeditions in East Africa, including tables of meteorological observations taken by M. Popelin. There is also a report on the "Conférence Géodésique Internationale de Munich," and an essay by Col. Verstraete on biological geography.

THE *Bulletin* of the Norman Geographical Society contains a paper by M. G. Gravier on M. Paul Soleillet's journey to Adrar between December, 1879, and May, 1880, as well as the continuation of M. Ch. Benner's journey from M'ruli to the capital of Unyoro.

THE Italian Expedition to the Antarctic Regions will not set out till 1882, but Lieut. Bove will shortly set out on board a whaling vessel to make a voyage of reconnaissance.

TWO Englishmen, with sixteen men belonging to an Indian convoy, are reported to have arrived at Yarkand from the direction of Tibet, whither they returned after visiting Kashgar.

M. RABOURDIN, who accompanied Col. Flatters on his survey for the proposed Trans-Saharan Railway, reports that he discovered numerous remains of cut flints, not less than eighteen manufactories being found in a length of 800 kilometres from Wargla. He also found remains of the great horned oxen which, according to Herodotus, were found in the country of the Garamantes.

DR. NACHTIGAL has furnished the *Tour du Monde* with a *résumé* of the concluding portion of the forthcoming volume of his "Reise in Afrika" in advance of publication, and it now appears in that periodical under the title of "Voyage du Bornou au Baguirmi," accompanied by a sketch-map and some very interesting illustrations.

WE hear that the Geographical Society of Marseilles have awarded their gold medal to Major Serpa Pinto for his journey across Africa.

ACCORDING to the *Echo du Japon* the King of Corea has been induced to make an offer of entering into treaties with foreign powers, through his fear of his kingdom being annexed by Russia, and he has despatched two envoys to open negotiations. Though the opening of Corea will hardly be of any great commercial importance, it will pave the way for interesting geographical researches in a country which is almost unknown, except from the imperfect accounts of Roman Catholic missionaries.

THE first volume of Lowenberg's "Geschichte der geographischen Entdeckungs- und Forschungsreisen," which treats

of voyages of discovery made during antiquity and the middle ages, as far as Magellan's first voyage round the globe, will be shortly published by Herr Spamer of Leipzig It will contain some 100 illustrations, besides maps, charts, &c.

CRITICAL TEMPERATURE OF ETHYLENE

M. AMAGAT (*Compt. rend.*[1] [1879], lxxxix. p 437, corrected *Beiblätter* [1880], iv. p. 19) has submitted hydrogen, oxygen, nitrogen, air, carbon monoxide, methane, and ethylene at temperatures from 18° to 22° to pressures ranging between 28 and 431 atmospheres, and finds that, except for hydrogen, the product $p v$ first diminishes and then increases as p increases, the most marked case being that of ethylene, for which the values of $p v$ at 31 58, 84 16, 398 71 atmospheres are proportional to 2 29, 1, 3 13 respectively. Dr. van der Waals deduced this general peculiarity theoretically in 1873, and showed that its markedness is the greater, the less the temperature of compression exceeds the critical temperature concluding, therefore, that for ethylene the critical temperature is not far below 18°, as M. Amagat has also surmised, he has recently (*Meded. der k Akad. van Wetenschappen in Amsterdam*, Mei 1880)[2] determined it directly by a Cailletet compression-apparatus, finding it to be 9° 2, and the critical pressure 58 atmospheres

On p. 55 of his dissertation "Over de Continuiteit van den Gas- en Vloeistoftoestand" (Leiden, 1873), van der Waals finds the characteristic equation of a gas in the form—

$$\left(p + \frac{a}{v^2}\right)(v - b) = R(1 + \alpha t),$$

where a, b, R are constants and α the coefficient of expansion, and on p. 79 *et seq* it is shown that at the critical temperature all three values of v given by this equation, which may be written

$$v^3 - \left\{b + \frac{R(1 + \alpha t)}{p}\right\}v^2 + \frac{a}{p}v - \frac{a b}{p} = 0,$$

are equal hence, if V is put for this common value of v, and T, P for the corresponding values of t, p, *i e* for the critical temperature and pressure, the theory of equations gives

$$3V = b + \frac{R(1 + \alpha T)}{P},\quad 3V^2 = \frac{a}{P},\quad V^3 = \frac{a b}{P},$$

whence

$$P = \frac{a}{27b^2},\quad V = 3b,\quad P V = \frac{a}{9b},\quad 1 + \alpha T = \frac{8a}{27 b R},$$

and also

$$a = 3PV^2,\quad b = \tfrac{1}{3}V,\quad R = \tfrac{8}{3}\frac{PV}{1 + \alpha T}.$$

The minimum value of $p v$ at any temperature t may be determined in the usual way by $\frac{d\, p v}{d v}$ being equated to zero, and, if p', v' are written for the corresponding values of p, v, there result

$$v' = \frac{V}{3(1 - \tau)},\ p' = 27(1 - \tau)(2\tau - 1)P,\ p'v' = 2(2\tau - 1)PV,$$

where

$$\tau^2 = \frac{b R(1 + \alpha t)}{a} = \tfrac{8}{27}\frac{1 + \alpha t}{1 + \alpha T}.$$

Thus a minimum value of $p v$ exists only when

$$1 > \tau > \tfrac{1}{2},$$

i e. only at temperatures that lie between

$$\frac{a}{b R \alpha} - \frac{1}{\alpha} \text{ and } \frac{a}{4 b R \alpha} - \frac{1}{\alpha}.$$

If p_1 represents the pressure of the gas when occupying unit volume at t, then

$$(p_1 + a)(1 - b) = R(1 + \alpha t),$$

and, p_1 being the value of $p v$ in this initial state, the markedness of the minimum value of $p v$ is greater the less

$$\frac{p'v'}{p_1} \text{ or its equivalent } \frac{(1 - b)(2\tau - 1)}{\tau^2 - b(1 - b)},$$

that is, since the sign of the t differential coefficient of this expression is the same as that of $(\tau - b)(1 - b - \tau)$, the less t, provided that

$$1 - b > \tau > b,$$

or that the temperatures lie between

$$\frac{a(1 - b)^2}{b R \alpha} - \frac{1}{\alpha} \text{ and } \frac{a b}{R \alpha} - \frac{1}{\alpha}.$$

If v represents the volume of the mass of gas which occupies unit volume at 0° under unit pressure, then

$$R = (1 + a)(1 - b),$$

as is taken in the following calculations.

In the case of ethylene van der Waals' experiments give $T = 9 2$ and $P = 58$; hence, by the above relations with $\alpha = 0 00367$,

$$\frac{a}{b(1 + a)(1 - b)} = 3\,489,\quad \frac{a}{b^2} = 1566,$$

which lead to a cubic equation that gives

$$a = 0\,00786,\ b = 0\,00224,\ R = 1{\cdot}0056,$$

so that the characteristic equation is

$$p = \frac{0\,0037(272{\cdot}5 + t)}{v - 0\,00224} - \frac{0\,00786}{v^2},$$

the pressure being reckoned in atmospheres, hence too $V = 0\,0067$ and $P V = 0\,39$ Further, when $t = 20$, the mean temperature in Amagat's experiments, $\tau = 0\,5547$, and thus by calculation $p' = 76{\cdot}25$, while Amagat's direct observations give $p' = 84$ approximately, so far justifying the the theory The temperatures for which $p v$ has a minimum value range from 678° to − 35°.

The intimate agreement between Amagat's experiments and van der Waals' formula (which is entirely independent of them) is shown by the following table, wherein the first column contains the pressures (expressed in atmospheres) employed by Amagat, the second his experimental values of $p v$ divided by 23500, and the third the values of $p v$ calculated for $t = 20$ from the formula —

p	$p v$ observed	$p v$ calculated
31·58	0·914	0·895
45·80	0 781	0 782
59 38	0 522*	0 624
72 86	0 416	0·387
84 16	0·399	0 392
94·53	0·413	0 414
110 47	0 454	0 456
133 26	0 520	0 520
176 01	0 643	0 642
233 58	0 807	0 805
282 21	0 941	0 940
329·14	1·067	1 067
398 71	1 248	1 254

The only serious discrepancy occurs for $p = 59\ 38$, and van der Waals accounts for this by supposing that in Amagat's table 12263 is misprinted for 15263, so that the asterisked number should be 0·650; for by experiment he finds that the ratio of the values of $p v$ for $p = 45\ 80$ and $p = 59\ 38$ is 1 26 (the calculated ratio being 1 25), while Amagat's actual numbers give 1 50, but, when corrected, 1·20

For methane the equation of van der Waals' form that best satisfies Amagat's experimental values has for constants $a = 10^6 \times 2{\cdot}9$, $b = 53$, $R = 25525$, if $t = 20$, $\alpha = 0{\cdot}00367$, pressures being measured in metres of mercury, and this gives $-99\tfrac{1}{2}°$ for the critical temperature and $50\tfrac{1}{4}$ atmospheres for the critical pressure. The constants have large values here, for, as calculation shows, the mass of the gas considered is about $24\tfrac{1}{4}$ grams, which would occupy, at 0° under one atmosphere, about 33518 c c.

This discussion—with the numbers recalculated—by Dr. van der Waals of M. Amagat's experiments in connection with the critical temperature is here reproduced, together with the brief *résumé* of his theory (which has not hitherto appeared in an English dress), for ready application in other cases.

September 17 ROBERT E. BAYNES

[1] Since the following was written, M. Amagat has published further results, which do not however affect its main point

[2] Mr Dickson seems to have independently discovered (*Phil Mag* for July, 1880) the principles laid down by Dr. van der Waals in his above mentioned dissertation, pp 79-93, which is not sufficiently known in England

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

CAMBRIDGE —The Natural Science Tripos Class List has just been issued There are eight names in the first class, eight in the second, and fifteen in the third Of those in the first class three attain their first class for Physics and Chemistry, viz.: Fleming, St. John's (distinguished in Physics); S L. Hart, St. John's, and Heycock, King's. Two attain their first class for

Botany: Hillhouse, Trinity, and Hoffmeister, Caius (distinguished), and three for Zoology, Anatomy, and Physiology: Caldwell, Caius; Pigeon, Christ's, and Shaw, Sidney

Mr. J. A. Fleming, B.A., of St John's, has been appointed to the new post of Demonstrator of Mechanism and Applied Mechanics, Mr Fleming is a distinguished graduate of London University, as well as having attained distinction in Physics, with first class honours in the Natural Science Tripos of this year

Mr. J. J. Lister, B A, of St John's College, has been appointed Demonstrator of Comparative Anatomy, in place of Mr A C Haddon, who has been appointed to the Professorship of Zoology and Comparative Anatomy in the Royal College of Science, Dublin, vacated by Prof. Bridge

Mr. A H Cooke, B A, Fellow of King's College, has been appointed Curator of the Zoological Museum.

SCIENTIFIC SERIALS

SOCIETIES AND ACADEMIES

London

Zoological Society, December 14.—Prof W H Fowler, LL.D., F.R.S., president, in the chair.—Mr. Sclater exhibited and made remarks on a skin of a brown female of *Pauxis galeata*, formerly living in the aviary of the late Mr G. Dawson Rowley, F Z S.—Dr. A. Gunther, F R S, exhibited and made remarks on a skin of a new species of *Rhynchocyon* from Eastern Africa, discovered by Dr Kirk.—Prof. T. H. Huxley, F.R S, read a paper on the application of the laws of evolution to the arrangement of the Vertebrata, and more particularly of the Mammalia.—Lieut. Col. H. H Godwin-Austen, F R.S, read a paper on the anatomy of *Ferussacia gronoviana*, Risso, from Mentone, pointing out its general relationship with *Lovea tornatellina*, Lowe, of Madeira, and with *Ferussacia folliculа*, Gronov., from Algiers.—Mr Arthur G Butler read a paper on a second collection of Lepidoptera made in Formosa by Mr. H. E Hobson. Thirty-three new species were found in this collection.—Mr Oldfield Thomas, F.Z.S., read a paper containing the description of a new species of *Reithrodon*, obtained in Venezuela by the late Mr D. Dyson, which was described as *Reithrodon alstoni*.—Dr. A. Gunther read a paper containing notes on some rare reptiles and batrachians now or lately living in the Society's Gardens.

Physical Society, December 11.—Prof. W. G. Adams in the chair.—New Members: Mr. W. R. Brown, Mr. T. Mightson, C.E.—Lieut L. Darwin read a paper on the rate of loss of light from phosphorescent substances. His experiments were made at Chatham on Balmain's luminous paint, by comparing the intensity of the phosphorescent light with the light of a sun-burner; the luminous surface being kept cool by placing ice and water near, as a slight increase of temperature in the surface considerably increases the quantity of light given off in a certain space of time. The supply of light was communicated to the paint from a mirror reflecting sunlight. A table and a curve exhibited to the meeting showed the rate of loss found by Lieut. Darwin. It is independent of the original intensity of the illumination. According to the curve the light diminishes very nearly in proportion to the square of the intensity of the light. In a report on the use of Balmain's paint in mines, it had been stated that the phosphorescence became brighter a few minutes after exposure in the dark, but the curve showed this to be an error, due probably to the fact that the eye becomes more sensitive to light after being a few minutes in the dark. Mr Pearsall emphasised the advantages of such a light in fiery mines. Prof Guthrie inquired if the phosphorescent power grew weaker by time, and Lieut. Darwin instanced a specimen eighty years old to the contrary, but Dr W Crookes stated that these luminous substances give off sulphuretted hydrogen in damp air and deteriorate. If sealed in a vacuum they would not. Dr. Crookes remarked that in Balmain's patent it was stated that the phosphorescence died out sooner when exposed to a strong light for a short time than to a weak light for a longer time; but Lieut. Darwin thought this was explained by the slow decrease in the lower part of the curve when the phosphorescence became faint. Mr R J. Lecky mentioned that Evelyn in his Diary (1650) describes a phosphorescent powder as "bottling up" sunlight. Dr Coffin inquired if short exposure to strong light was equivalent to long exposure to feeble light. Lieut Darwin thought not.—Dr C R Alder Wright read a full paper on the determination of chemical affinity in terms of electromotive force. He considered first the value of the B A unit of resistance, which from different experimenters might be taken as really 1.005 earth quadrants per second, or not more than half per cent. out. Clark's element when carefully prepared was practically correct at 1.457 volts, and it kept constant for three or four months after being made, but deteriorated thenceforth some 3 per cent in about two years. The deterioration was assisted by air, which could not be well excluded by the paraffin cork, as it cracked. If sealed in a Sprengel vacuum the element lasted better. Joule's mechanical equivalent of heat (*J*) he estimated at 42×10^6, or not over 1 per cent greater than Joule's water value. The chief result of Dr Wright's researches was the conclusion that the action of a current in electrolysis is to decompose the electrolyte into "nascent" products which evolve heat in changing into ordinary products of electrolysis. These nascent products may be the ultimate atoms composing the molecules of the ordinary products, and the heat is given out in these atoms coming together to produce molecules, say of oxygen and hydrogen in the case of water. A number of deductions from this theorem are verified by experiment. One of these is that no gas battery can give a higher E M F than 1·5 volts. A result, not before published, is that the E M.F of a Daniell cell is a function of the current and is a maximum when the current is indefinitely small. The variation may amount to 10 degrees. Therefore all methods of determining resistance by means of two currents of different strength are inaccurate. Dr Wright's experiments also verified Faraday's law that conduction in an electrolyte is always accompanied by electrolysis. Prof. Adams inquired if Dr Wright had seen the letter of Prof Rowland's assistant to the effect that Dr. Wright's former estimate of the ohm was on the wrong side of unity. He had been too busy to see it. Prof Foster thought that the variation of E M F in a cell with the current was to be expected, and was probably due to the slowness of diffusion. Dr Wright thought diffusion would account for it. Dr Lodge said that there was no way of measuring the resistance of a cell except by employing two currents of different strength, and therefore it was necessary to know the law of variation of E M F. with current strength. Dr Wright stated that he had found two methods of proceeding with currents of the same strength. With regard to the deduction of Dr Wright that no current passes without producing electrolysis, Mr Walenn inquired if the ordinary law of solution held when there was no evolution of hydrogen, and was answered in the affirmative.—Prof. Guthrie cited the experiments of Mr. C V Boys and himself on the conductivity of liquids as an instance of a current passing without electrolysis, or if there was decomposition it was followed by instant recomposition. Dr. Wright thought there must be electrolysis in Dr. Guthrie's experiments (which were conducted by rotating a glass vessel filled with the liquid between the poles of a magnet, after Arago's experiment), because some two parts of the rotating vessel would be at different potentials, and a current would be set up in the liquid.—The Society then adjourned till after Christmas.

Paris

Academy of Sciences, December 13.—M. Edm. Becquerel in the chair.—The following papers were read:—Solid and

liquid products which continued issuing in April, 1880, from a crater of Dominica (English Antilles), by M. Daubrée. The lake of boiling water which filled the crater in January had shrunk to a boiling-spring, the dark liquid from which joined a river. The weight of solid matter is nearly half the liquid, and mainly consists of silica and alumina; there is also iron oxide, with carbonate of lime, &c. Chloride of potassium abounds in the water.—Order of appearance of the spikelets in the ear of Lolium, by M. Trécul.—On the orbit described by a material point which is attracted by a spheroid, by M Gyldén.—M. Abria was elected Correspondent in Physics in place of M. Lissajous —Application of the theory of germs to parasitic champignons on plants, and especially to diseases of the vine, by M Cornu. In some cases the diseased leaves may be variously utilised, after such treatment as will prevent the spores being disseminated when their time of vegetation comes. Other kinds of parasites do not allow of the leaves being used as food for cattle, compost, or litter. Their dormant spores are not killed by digestion or putrefaction of tissues; after prolonged burial they may produce new germs. The *débris* in that case should be burnt. Oïdium and anthracnose exemplify the former, *peronospora* the latter —On the discovery of the winter egg in the Eastern Pyrenees, by M. Campana He found three in the end of September.—On a process of preparation of sulphide of carbon in the solid state for treatment of phylloxerised vines, by M. Lafaurie. He solidifies the sulphide by making an emulsion of it with a solution of algæ (Japanese moss does very well). The proportion of sulphide may be varied up to 80 per cent. It evaporates very slowly, so that vapours can be thus maintained a long time about the roots —Swift's comet (*e* 1880), by MM. Schulhof and Bossert.—Influence of the slope of refringence on astronomical refraction, by M. Glasenapp. By this term he denotes the effect of atmospheric layers of equal density not being generally distributed in concentric surfaces on the earth's surface (as they are supposed to be in all theories of astronomical refraction) He proposes to investigate the influence of this phenomenon and its law of variation; to find whether it have an annual period, and if so, of what nature, to study the influence of this on the annual parallax of fixed stars and their aberration, also to study lateral refraction.—On the contact of conics and surfaces, by M. Darboux —On a class of linear differential equations, by M Appell.—On the integration of equations with partial derivatives of the first order, by M. Collet.—On linear differential equations of the second order, by M Mittag Leffler.—Reclamation of priority on the subject of the law of corresponding boiling temperatures, by M Duhring —On radiophony (second note), by M Mercadier The sounds may be got from oxyhydrogen lamps and gas lamps without concentrating lenses, if the lamps be brought very near the (glass) interrupting wheel, and the rays limited by a diaphragm with aperture. A copper disc (0 002 m. thick) was placed near the wheel, and heated on the side opposite to that of the wheel with an oxyhydrogen blowpipe. Sounds were heard when the disk still remained invisible in the dark (though louder when the disk was raised to a dark or bright red).—On new and economic methods of producing intermittent luminous signals, by M. Mercadier. Instead of using a diaphragm with a constant source of light, he varies the source; *e g* by introducing oxygen suddenly into a low flame This is done by pressing a key, and so releasing from pressure a tube conveying the oxygen.—On the absorption-spectrum of ozone, by M. Chappuis. Eleven dark bands are observed in the visible spectrum, and several correspond with telluric bands of the solar spectrum.—Action of hydrochloric acid on metallic chlorides, by M. Ditte —Action of hydrofluoric acid on bichromate of ammonia, by M. Varenne.—On chlorised derivatives of strychnine, by MM Richet and Bouchardat They have isolated three such compounds, retaining in different degrees the chemical properties of strychnine.—On the cause of spontaneous alteration of the raw sugar of cane, by M. Gayon. He gives reasons for thinking this process a true fermentation.—On the variations of luminous sensibility according to the extent of the retinal parts excited, by M. Charpentier. One region, seventeen to eighteen hundredths of a millimetre in diameter, and corresponding to the *fovea centralis*, requires a determinate quantity of light, independent of the extent of surface, to excite it. In other parts the minimum illumination is proportional to the surface.—Anatomic researches on *Onchidium*, Cuv. (*Oncidiella celtica*, Gray), by M. Joyeux Laffine.—Serpentines of Corsica, their age and origin, by M. Dieulafait. M. Hebert dissented from some of the results in this paper.

VIENNA

Imperial Academy of Sciences, December 16.—Herr v. Burg in the chair.—Table of the most important relations of astronomy and geography, by Herr Letoschek.—Further researches on identity of the comets 1869 III. and 1880 *e*, by Herr Zelbr and Dr. Hepperger —On leucæmia, by Herr Ludwig.—Fourth report of the Prehistoric Commission, containing (1) Szombathy on this year's prehistoric investigations and excavations at Kiritein and Mokrau in Moravia; (2) Luschau on several old burial-places in Bosnia and Dalmatia; (3) Heger on skeleton graves of Tlonic, grave-mounds at Tschemin (Bohemia) and at Wassering in Lower Austria, and tumuli at Mars in Hungary.—Theoretical researches on the displacements of the radiation-points of dissolved meteor-streams, by Herr v. Riessl.—Application of hyposulphate of soda to separation of copper from cadmium, by Herr Vortmann —Some experiments on an earth-magnetic inductor, by Herr Stefan.

BERLIN

Geographical Society, December 4 —Dr. Nachtigal in the chair.—It was stated *inter alia* that Herr Flegel, who is busy in the Niger region, had gone from Lukodja to the King of Nupe or Nife, seeking letters of introduction to the rulers of the Haussa States, so as to make a safe journey up the Niger, especially on the stretch between Tawa and Sai. He had a friendly reception, and wrote in good hopes (October 10). From Sai he means to go to Sokoto, the chief town of the Haussa States, and there to get letters for the ruler of Adamaua. A large collection of ethnological objects of the Niger region is looked for in Berlin —Rumours of the death of Herr Hildebrandt in Madagascar prove false A letter from him dated Krabé in Betsileo (Central Madagascar), September 2, 1880, states that he had made a journey, rich in results, from the West Coast to the Central Plateau, but his health broke down, when he was two hours' journey from the capital, to which however he was shortly brought by Herr Cousins and tended for a time in the Norwegian mission-house till able in July to visit the hot springs of Siralé (for health). He discovered in the moor at Siralé the skeleton of an extinct species of hippopotamus —Dr Kiepert gave details of Mr. Doughty's expeditions in Central Arabia, which have cleared up much of the physical geography of that region.—Dr. Holub spoke on the Maruthameich in southern interior Africa, north of the lower, and about the middle course of the Zambesi

PERUVIAN BARK

Peruvian Bark: a Popular Account of the Introduction of Chinchona Cultivation into British India. By Clements R. Markham, C.B., F.R.S. 1860–1880. (London: John Murray, 1880.)

"THE enterprise undertaken by me in 1859 of introducing the cultivation of Peruvian bark trees into British India and Ceylon is now an assured success." With these words Mr. Markham begins his preface, and a perusal of the convenient history he has put together of the gradual steps by which during the past twenty years this success has been reached, enables us to fully share the satisfaction with which they must have been written. Not merely has a cheap supply of febrifuge alkaloids been brought within reach of the fever-haunted population of India, but a new and highly-profitable industry has been opened to the planters of our tropical colonies, and the yield of an inestimable drug placed beyond risk of exhaustion.

Enthusiasm is in most enterprises essential to success. If a certain tinge of impracticability often accompanies it, a moderate experience of human nature disposes us to regard this with a good deal of toleration. We may as well confess at once therefore that the pleasure with which we have studied Mr. Markham's pages would have been greater but for his insistance throughout on two grievances, in neither of which do we find ourselves in any way persuaded by his advocacy. One of these—the other is more serious, and must be adverted to further on—is irritating in inverse proportion to its importance. The names of genera employed in systematic botany are Latinised forms, very arbitrary, and often, it must be allowed, unscholarly in their construction. But they are symbols or dockets under which scientific information can be arranged. If there is one thing about which botanists, of whatever nationality, are agreed, it is that the docket, having once been promulgated and brought into use, shall not be meddled with. It may be abolished or merged in some other, but being a mere symbol it cannot be tampered with without disturbing all kinds of mechanical aids to study, such as indexes and catalogues, and so adding to the worry of life. From a literary point of view the correction of *Cinchona* into *Chinchona* may be desirable, but the trouble of having two spellings in circulation is too great a price to pay for the mere satisfaction of literary propriety. It cannot be said therefore that this is merely a literary question like such spellings as those of diocess and chymistry affected by the *Times*, while from a technical point of view it has been already discussed and conclusively decided against Mr. Markham in the pages of this journal.

The genus *Cinchona*—as we must still beg leave to call it—includes all the plants at present known to yield quinine and allied alkaloids. It has rather more than thirty species, some of which however are medicinally valueless, while the rest vary individually in the amount and character of the alkaloids they yield. The native habitat of the genus is very restricted; it is only found on the Andes between 10° N. and 19° S. lat., and between 2500 and 9000 feet of elevation. Besides this the several species are closely limited to particular portions of the general area.

The native inhabitants seem to have set little store on the febrifugal properties of the cinchonas, and indeed to have been little aware of them except in the neighbourhood of Loxa, where a Jesuit was cured in 1600 of a fever at Malacotas by Peruvian bark, and to this day the local prejudice against its use is very strong. In 1638, however, the Countess of Chinchon, wife of the Viceroy of Peru, was cured of intermittent fever by bark sent by the Corregidor of Loxa. The remedy, whose reputation was now established, was carried by her to Spain in 1640, and became known as *Pulvis comitissæ*. In 1670 it was sent to Rome by the Jesuits and distributed to members of that order throughout Europe. Hence it came to be called Jesuit's bark, and it is interesting to find that its merits became accordingly a party question between Protestants and Catholics.

For more than a century (till 1776) the only bark met with in commerce was that brought from the neighbourhood of Loxa. This was called Quinquina, from the Indian name *quina-quina*, *quina* meaning bark, and the reduplication the possession of medicinal properties. The plant producing the bark was described by Linnæus under the name of *Cinchona officinalis*, to be rechristened afterwards by Humboldt and Bonpland *Cinchona condaminea*, a change correctly rejected by Mr. Markham, following Sir Joseph Hooker, and, be it remarked, on precisely the same grounds as those on which the rechristening of the genus as *Chinchona* must also be rejected.

As early as 1735 Ulloa represented to the Spanish Government that the Loxa forests could not long survive the reckless treatment to which even then they were subjected. And this was in spite of the intelligent efforts of the Jesuits, who endeavoured to enforce replanting as a religious duty. The Loxa bark, eventually distinguished as Crown bark from being reserved, when other kinds became known, for use in the Royal Pharmacy at Madrid, is represented in old collections of Materia Medica, such as that of the College of Physicians, by massive fragments which must have been detached from very old trees. Mr. Markham tells us that it is now only found in commerce in the minutest quills. As the Loxa bark became scarce the search after other supplies of cinchona bark was stimulated. The botanical expedition of Ruiz and Pavon sent by the Spanish Government in 1777 resulted in the discovery of seven species of *Cinchona*, yielding grey bark, near Huanuco in Northern Peru. Mutis, another Spanish botanist, believed that he first detected a *Cinchona* in Columbia in 1772, though a resident in Bogota challenged his claim to priority.

The well-known "red bark" of the slopes of Chimborazo seems to have been known early in the last century, and later to have found its way into European markets, though it was not till 1857 that the plant yielding it was clearly identified by Dr. Klotzsch. The yellow or Calisaya barks of Bolivia, first discovered by Haenke in 1776, did not become of commercial importance till 1820, when quinine, the most important active principle of Peruvian bark having been isolated by the French chemists, Pelletier and Caventou, yellow bark was recognised as richer in it than any other kind.

It is not necessary to follow in detail the interesting account given by Mr Markham of the recklessness with which the natural supplies of Cinchona bark were drawn upon The inconvenience of a precarious dependence upon the South American forests has for at least forty years occupied the attention of scientific men in Europe Royle, in 1839, urged the introduction of Cinchonas into India, and pointed out the Nilgiri Hills as a suitable locality The Dutch botanists had been no less urgent that the experiment should be made in Java, and Hasskarl was commissioned to proceed to Peru in 1852 to obtain seeds. In this he succeeded, but the bulk of the seeds eventually proved to belong to a species worthless medicinally, which was afterwards named *C. Pahudiana* He also obtained, by the aid of a Bolivian named Henriquez, 400 plants of the yellow bark, *C Calisaya*, only two of which unfortunately survived in Java. The mishaps of the Dutch enterprise cannot be followed here, instructive as they are to any one interested in the cultivation A happy accident, to be presently alluded to, was a kind and well-deserved turn of fortune in its favour, and a greater measure of success than could ever have been hoped for now seems assured to it

The Government of India in 1852 first proposed the introduction of cinchona into that country, and several abortive attempts to effect it were made with the aid of the Foreign Office, but without success In 1859 Mr Markham was officially employed by the present Lord Derby, who was then Secretary of State for India, to undertake a mission to South America for the purpose His previous travels in the Cinchona region, though for ethnological and not for botanical inquiry, and his knowledge of the Spanish and Quichua languages singularly fitted him for the task The plan laid down by him was extremely comprehensive, and has at last been fully carried out, or nearly so It was nothing less than the introduction into India of all the species of *Cinchona* yielding bark of known commercial value This plan was adopted as it was *à priori* uncertain which kinds would turn out best adapted for Indian cultivation, and it was desirable that all should be tried, it involved no less than five distinct expeditions to the different districts of the Andes already mentioned.

Mr Markham visited himself in 1860 the yellow bark region in Southern Peru and Bolivia, accompanied by a young gardener named John Weir, recommended by Messrs Veitch The plants collected reached England in fifteen Wardian cases, but the heat of the Red Sea was fatal to them and they all eventually died A supply of seed which Mr Markham had arranged for at Caravaya arrived in India in 1865 and germinated satisfactorily

Mr Pritchett, who had travelled in the Huanuco district, was employed to make a collection of the grey bark plants, and to these also the Red Sea was fatal, but the loss again was retrieved by the safe transmission to India of seed which grew well The red bark region was visited, at the suggestion of Sir William Hooker, by the well-known botanical traveller, Dr Spruce, who was residing in South America at the time, and he was accompanied by Robert Cross, a Scotch gardener, recommended by the Kew authorities. The plants collected by Dr Spruce were more fortunate, and reached India in good condition in 1861 under Mr. Cross's charge. This skilful collector then returned to South America and obtained the seed of the crown bark from the Loxa forests, which reached India in 1862 and germinated abundantly Before returning to Europe he visited the Columbian forests in 1863 and secured seed of Pitayo bark (*C. Pitayensis*), which however had lost its vitality before it arrived in India He was therefore sent again in 1868, and this time secured both plants and seeds, which were transmitted to India in a living state The only remaining kinds of importance which had not been introduced into India were the Calisaya de Santa Fé, yielding soft Columbian bark, and *Cinchona cordifolia*, yielding hard Carthagena bark, to procure these Mr Cross was despatched on another mission, from which he returned in 1878, bringing cuttings of both kinds, and these were successfully propagated at Kew, which had indeed in every case been made the depôt for the receipt of the successive consignments and their despatch to India The Carthagena bark is now well established in India, Jamaica, and it is hoped in Ceylon But the fate of the Calisaya de Santa Fé is still doubtful, as one consignment succumbed to the heat of the Red Sea, which is so great an obstacle to the transport of plants, intolerant of great heat, and no news as to the second instalment taken out in charge of Mr Cross has yet reached this country

We must but very briefly hurry over the interesting pages in which Mr Markham describes what has been done in India Red bark has everywhere taken the lead Next to this, in the Nilgiris, crown bark has succeeded best, the other kinds have made but little progress Unfortunately little care seems of late to have been taken in Southern India to keep the different kinds distinct, and as the species hybridise very freely it is not easy to say what some of the plants actually in cultivation precisely are. In the Himalayas, however, besides red and crown bark-plants, *C. Calisaya* (yellow bark) and *C micrantha* (one of the species yielding grey bark) also do well

The share taken by Kew in this important enterprise enabled the advantages secured by the Indian Government to be extended to other tropical possessions in the Empire Sir William Hooker was allowed to transmit a share of the seeds and plants to Ceylon, Jamaica, Trinidad, Mauritius, and St Helena In the three latter islands the cultivation has made but little progress, in the first it is now one of the staple resources of the planters, while in Jamaica the crown and red bark bring in an annual revenue to the Government, which leaves an ample surplus after paying the whole expenses of the botanical department

One of the most singular incidents in the whole story has still to be told Mr Charles Ledger, who had long resided in South America, hearing of Mr. Markham's enterprise, employed a native servant, Manuel Mamani, to collect seed of the best Calisaya or yellow bark tree Four years elapsed before he succeeded, as each year the blossom of the trees was destroyed by frost These seeds were transmitted to London to the care of Mr. Ledger's brother, and it is believed were offered to the Indian Government, who refused to purchase them. Half was eventually sold to the Dutch Government and half to Mr. Money, a planter on the Nilgiris. This fortunate purchase has put quite a

new face upon the cultivation in Java The bark of some of the trees has yielded as much as 10 per cent of quinine; and the news of this remarkable result has produced much the same effect on Cinchona planters in Ceylon and Southern India as the discovery of a gold-field on the inhabitants of an Australian city The Java officials have however behaved with singular liberality in the matter, and in the course of a few years it cannot be doubted that Ceylon will be abundantly supplied with this valuable kind, which, there seems reason to think, may prove to be a distinct species Part of the seed sent in the first instance to the Nilgiris seems to have found its way to Sikkim, and the Government plantations there are believed to be in possession of a strain of Calisaya, little if at all inferior to that possessed by the Dutch.

The Government of Bengal have effected an enormous saving by using, in hospitals and dispensaries, instead of quinine imported from Europe, the febrifuge manufactured at the Sikkim plantations The Government estimated that in consequence, by the end of 1879, "the plantations will have cleared off the entire capital that has been invested in them"

And this leads us to what is really the painful feature in Mr. Markham's book. He complains in repeated and in bitter terms of the want of justice which has been shown to those whom he employed in the business of collecting "Those who did the work have not received fair recompense for most valuable services" It is rather singular to find that he adduces in support of this statement the case of Mr Ledger, who was not even in any way commissioned to do what he did But the remuneration which his actual agents received was the ground of no complaint on their part, and was in point of fact liberal compared with that which is given to the collectors who are constantly employed by the great nurserymen, and who too often lose their lives in their arduous pursuits without the satisfaction of feeling that they are doing so in an enterprise like this of lasting utility But we fear that if Mr Markham's assistants have reason to complain the blame must, on his own showing, be laid at his own door He tells us (p 271) "The system I adopted was to include very slight remuneration in the original agreements. *Thus the loss to Government would be insignificant if the work was not executed satisfactorily* If, on the other hand, the arduous tasks were successfully performed . I anticipated no difficulty in obtaining fitting recognition for such distinguished services" We leave our readers to judge of the probability of such a scheme answering Mr Markham's expectations. We may go further, and ask how the claims would have stood if, notwithstanding all the pains that were taken, the cultivation of Cinchonas had fared in India—as might even have happened—no better than it at first did in Java.

But there are many other things pleasanter than this which we should like to touch upon if this review had not already run to an inordinate length. So many Englishmen are now in one way or other interested in colonial industries that it will be strange if this interesting book does not find as many readers as it deserves. Besides a complete history of the Cinchona enterprise in the Old World, it gives, in an appendix, accounts of some other South American vegetable products, notably india-rubber. The steps taken at Mr Markham's instance for the introduction into India of the most important rubber-yielding plants of the New World have been from time to time recorded in our pages We have only to repair one inadvertent omission on Mr Markham's part, and point out that the transmission of the Para rubber plant to India was secured by the exertions of Mr Wickham, as recorded in the Kew Report for 1876, p 8

PRACTICAL BLOWPIPE ASSAYING

Practical Blowpipe Assaying By George Attwood. With Seventy-four Woodcuts (London: Sampson Low, Marston, Searle, and Rivington, 1880)

THIS book shows many signs of carelessness on the part of the author At the very outset, in the Introduction, we meet with strange statements Mr Attwood divides the elements into those which are of commercial value and those which are of no commercial value In the latter class we find Uranium and Tungsten, surely the author does not intend to deny the value of pitchblende and wolfram He classifies zirconium among the non-metallic elements.

The first part of the work describes the reagents and apparatus, the second, we are told, contains the modes of determining any one of the sixty-four well-recognised elements, and in the third part we have the methods adopted by the author for making quantitative assays by the blowpipe Finally, Part IV. contains some tables showing the English and American values of gold according to its fineness, and the value of gold coins in the United States

The apparatus employed is much the same as that recommended by Plattner Like Neumann, Mr Attwood very wisely uses riders with his balance instead of the very small weights supplied by some of the other Freiberg opticians, but the balance would be improved by the addition of a movable arm for shifting these riders The steelyard devised by the author will probably be of use to explorers From practical experience with the batea I can fully endorse all that is said in its favour, but why are the merits of the iron pan ignored? It has the advantage that it will stand rougher usage than the batea Again, for washing a sample of tin ore nothing will beat the Cornish vanning shovel

I regret to see no mention of the useful little pastilles and crucibles made out of charcoal powder, proposed by Griffin thirty or forty years ago and adopted by Plattner Col. Ross's aluminium plate for sublimates seems also to have escaped Mr Attwood's notice.

With reference to the list of reagents I must remark that the author does not name all the reagents which his tests require, whilst others are inserted which he does not appear to put to any use I should be glad to know what he means by inserting "nitrous acid" among his reagents. This is not a misprint for "nitric acid," because that acid has been already named

The plan of the second part of the work is not one which I should recommend. It simply contains a list of tests for the various elements, but gives no systematic scheme for making the examination of an unknown substance. I fear that the "direct" method advocated by Mr. Attwood will often prove a very tedious one Many of the tests themselves are not so complete as they

ought to be In describing the tests for barium it is said that the bead "can be flamed," but no explanation is given of the process of flaming The capital test for bismuth with potassium iodide and sulphur is entirely ignored

I now come to the third part, which treats of quantitative assays. Mr Attwood's plan of making a check assay in every case with a small quantity of the pure metal is certainly calculated to give the operator confidence in his results The author adopts $1\frac{1}{2}$ grain as the amount of ore to be taken for an assay. I think he would have done better to have followed Plattner and used the French weights, because there is less chance of making errors where each milligramme means 1 per cent

For the silver assay Mr. Attwood employs pieces of ordinary charcoal instead of the far more convenient and portable charcoal crucibles designed by Plattner He also describes a crucible assay for silver ores, which does not appear to possess any advantage over Plattner's scorification method

There is one most unfortunate error in the book to which I feel bound to call attention. Mr Attwood gives some tables for calculating the number of ounces of gold or silver per ton from the results of assays of $1\frac{1}{2}$ grain of the ore In an unlucky moment he forgot that gold and silver are weighed by *troy* weight, and calculated his tables for *avoirdupois* ounces. The consequence is that these tables are not only valueless, but also highly misleading Let us take one case as an example Suppose that $1\frac{1}{2}$ grain of ore had yielded 0·01 grain of fine metal We look down the table (p 117), and find, according to Mr. Attwood, that the yield would be 238·93 oz per ton, in reality the yield should be 217·77 oz

Some neat little retorts have been designed by the author for distilling ores of mercury and amalgam, but he does not mention Kustel's assay

On coming to the tin assay we have the peculiar statement that silica may be separated from tin ore by boiling it with hydrochloric acid "The assay being finely powdered, the silica is dissolved." "The dissolved silica is decanted off" (p 158). Cornish mine agents will be surprised when they are told that, in order to obtain correct-results, it is necessary to wash or van as much as *5 lbs.* of an ordinary tin ore (p 159)

Under the head of nickel no mention is made of the valuable ores from New Caledonia.

Small mistakes are numerous The size of a box is said to be "twelve inches square" (p 3), we note also "*a* most useful addend*a*" (p 24), "chloride of ammoni*a*" (p. 33), "manganite" instead of manganate (p 53), and permanganate (p. 54) The term "raw iron" is used frequently instead of "pig iron," and shows that the author has copied Cornwall's translation blindly. Coal, anthracite, and graphite are said to "volatilise" when heated in the platinum spoon (p 82) Sieves are made with 2000 holes per "linear" inch (pp 100 and 137). In the description of cupellation (p 106) we read, "The lead parts with portions of its oxygen to the copper and other base metals."

In conclusion I think that the value of the book would be increased if a list of *errata et corrigenda* were inserted, correcting some of the errors which, I regret to say, impair its general usefulness. C. LE NEVE FOSTER

OUR BOOK SHELF

Uber die von den Trichopterenlarven der Provinz Santa Catharina verfertigen Gehause. Von Dr. Fritz Muller. *Archivos de Museu national.* Vol iii pp. 99-134, and 209-214. Rio de Janeiro, 1880. (Aus dem Portugieischen ubersetzt von dem Bruder des Verfassers, Dr. Hermann Muller in Lippstadt)

DR FRITZ MULLER has for some years been engaged upon an investigation of the habits of the Caddis-flies of Santa Catharina, and has shown extraordinary skill in breeding these insects, a matter always difficult, and especially in the case of those that inhabit running water The results of his researches were foreshadowed in various notes published in the *Zoologischer Anzeiger* and in the *Transactions* of the Entomological Society of London for 1879 But it was well known that the extended information and figures would be given in the Rio de Janeiro *Archivos* As this publication is somewhat difficult to obtain, and as most of us are not familiar with Portuguese, Dr Hermann Muller has conferred a great boon by publishing a translation of the paper (accompanied by the two folded plates) in the *Zeitschrift fur wissenschaftliche Zoologie* for the present year (pp 47-87, plates iv and v.). It is needless to state that the details are of the greatest interest, and we have here the most important contribution to the natural history of *Trichoptera* that has appeared since the publication of Pictet's "Recherches" on the species of Geneva, and worked out in a far superior manner. We cannot here even allude to most of the many marvels of insect-architecture and habits that Dr Fritz Muller has revealed. Some of the most interesting are the numerous forms of *Helicopsyche*, which build little sand-cases so like shells that they have been described as such, those *Dentalium*-like cases, originally noticed by Aug. St Hilaire as *Grumicha*, which name our author retains, those instances of parasitism (or worse) in which a larva of one species dispossesses that of another of its house and converts it to its own purposes, those very numerous forms of *Hydroptilida*, the most minute of all *Trichoptera*, with cases of the most varied and wonderful structure, above all, that most interesting fact that the rain-water which collects at the bases of the leaves of some *Bromeliaceae* has a special fauna of its own, including at least one Caddis-worm The descriptions of these and many others will be read with delight by every biological student, and we hope Dr Muller will follow up the paper by records of further discoveries, for here, as in all his works, the evidences of superior powers of observation strike one on every page

The plates are excellent, and aid much in a realisation of the descriptive portion Dr Muller's artistic powers are so marked that we cannot but regret he has not furnished details of the form and structure of the perfect insects also, which would have greatly aided systematists; in fact the perfect insects are only alluded to in a casual manner

Voyages of the Elizabethan Seamen to America Thirteen Original Narratives from the Collection of Hakluyt, Selected and Edited, with Historical Notices, by E J. Payne, M.A. (London. De La Rue and Co, 1880)

WE do not quite understand Mr Payne's reason for publishing this selection from Hakluyt's classical collection of voyages The selection is, however, judicious, and cannot fail to be interesting, and at the same time instructive, to those who desire to become familiar with the first beginnings of English conquest in America Mr. Payne's familiarity with the subject of British colonisation, as exemplified in his excellent little "History of European Colonies," specially qualifies him for making such a selection as the present. His brief Historical Introduction enables the reader to understand the special significance of the voyages contained in this volume. He

shows the various causes in operation at the time to instigate such voyages, causes mainly political and commercial. Other influences were however at work, not the least of which was "the total transformation which astronomy and geography had undergone" during the sixteenth century. The narratives here given are those of Hawkins's and Frobisher's three voyages, Drake's voyages of 1577 and 1585, Gilbert's voyage of 1583, Amadas and Barlow's voyage, 1584, Cavendish's first and last voyages, and Raleigh's voyage to Guiana. Prefixed to each narrative is a short historical introduction.

LETTERS TO THE EDITOR

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.

The Editor urgently requests correspondents to keep their letters as short as possible. The pressure on his space is so great that it is impossible otherwise to ensure the appearance even of communications containing interesting and novel facts.]

Black Sheep

THE following extract of a letter from Mr. Sanderson of Chislehurst, who permits me to publish it, seems worth placing on record. It relates to the former frequent appearance of spotted or black sheep in the Australian flocks, as long as animals thus coloured were of use to man, although they were never, as far as Mr. Sanderson knows, separately bred from, and certainly not in his own case. On the other hand, as soon as coloured sheep ceased to be of use they were no longer allowed to grow up, and their numbers rapidly decreased. I have elsewhere assigned reasons for the belief that the occasional appearance of dark-coloured or piebald sheep is due to reversion to the primeval colouring of the species. This tendency to reversion appears to be almost difficult quite to eradicate, and quickly to gain in strength if there is no selection. Mr. Sanderson writes:—"In the early days before fences were erected and when shepherds had charge of very large flocks (occasionally 4000 or 5000) it was important to have a few sheep easily noticed amongst the rest; and hence the value of a certain number of black or partly black sheep, so that coloured lambs were then carefully preserved. It was easy to count ten or a dozen such sheep in a flock, and when one was missing it was pretty safe to conclude that a good many had strayed with it, so that the shepherd really kept count of his flock by counting his speckled sheep. As fences were erected the flocks were made smaller, and the necessity for having these spotted sheep passed away. Their wool also being of small value the practice soon grew of killing them off as lambs, or so young that they had small chance of breeding, and it surprised me how at the end of my sheep farming experience of about eight years the percentage of coloured lambs produced was so much smaller than at the beginning. As the quantity of coloured wool from Australia seems to have much diminished, the above experience would appear to be general."

CHARLES DARWIN

The Nature of the Chemical Elements

DR. ARMSTRONG'S article in NATURE, vol. xxiii. p. 141, has brought to my mind some calculations I made more than a year ago to test a theory I had long previously entertained. Most of us who have paid much attention to the subject are agreed that the elements are capable, under exceptional circumstances, of profound chemical change. Mr. Lockyer is searching, with success as it appears, for contemporary evidence of this by examining the condition of the solar surface. The other line of evidence is historical, and turns mainly on the classification of the numerical values of chemical symbols. It is of course only with the latter that I have to deal.

The classifications proposed by Newlands and Mendelejeff are comprehensions of much similar preceding work. They appear to me to be faulty in two ways: (1) on account of the seriously large number of elements they wholly fail to include, and (2) because of the strong stress they lay upon arithmetical series of a rough *per saltum* character. As I do not know of any real case of *per saltum* chemical change, I do not think the elements should be classified on such a basis. What is wanted is a system capable of including—with exactness and not mere approximation—the whole of the elementary numbers, that system to be represented in the mathematical symbols of ordinary chemical change, and therefore free from a *per saltum* character. I have to a great extent succeeded in finding such a system, and the results of testing it at many points are as follow:—1. There is probably only one fundamental form of matter, and this, as has been previously supposed, yields our ordinary elements and many others by ordinary polymerisation. 2. Almost all the elementary numbers have been tried, and, with the exception of H and Cl, which are a little troublesome, they fall into order very exactly. 3. This order exhibits no discontinuity, and is similar to a case of ordinary chemical change. 4. There is clearly an upper limit to this order, in other words, elementary numbers of more than a certain magnitude appear to be impossible.

Sir B. C. Brodie's method is really a classificatory one; and I with others had been very desirous to read the Third Part of the Calculus, in which it was promised ampler play. It will be a matter for much regret if his premature death should have prevented this. But what he did publish was sound and sure: the first real symbols chemistry has yet enjoyed, and the only ones hitherto proposed whereby the process and the results of chemical change admit of unitary as well as kinetical representation.

EDMUND J. MILLS

Smokeless London

As I hope soon to have an opportunity of reading a paper on this subject before a scientific audience I need not occupy your valuable space by replying to your correspondents of last week in detail. I may say however that the scheme has been carried out in practice at a gas-work to which I shall afterwards refer. When it was found that the apparatus for making gas on an extraction of six hours was insufficient for supplying the wants of the long winter evenings the distillation was stopped when gas had been removed to the extent of 5000 cubic feet per ton. The larger quantities obtained from the coal per unit of time and the superior illuminating power obtained per unit of volume tided over the difficulty and rendered the existing plant sufficient. No practical obstacles were discovered in discharging the retorts. I do not think the difference between an extraction of 5000 and 3333 cubic feet per ton would make a material change in this respect. Mr. Mattieu Williams points out a much more serious obstruction in the plethoric indifference of the gas companies. In reply to E. R. F., I may say that the fuel resulting from a uniform extraction of 3333 cubic feet per ton is practically smokeless if it is taken hot from the retorts and immediately quenched with water.

Westminster, December 27 W. D. SCOTT-MONCRIEFF

Colliery Explosions and Coal-Dust

ACCEPTING Mr. Galloway's view that in many mines the extent and destructiveness of colliery explosions are due to the distribution of coal dust in the air, may I suggest the possibility of preventing the explosion from spreading beyond the sphere of the fire-damp by sprinkling the floors throughout, at certain regular intervals, with mineral oil? A shady road, with one such sprinkling, may be kept free from dust for several weeks during the summer, and the corridors of a mine, not being open to wind and rain, would of course remain wet for a longer period. A saucer filled with dust and treated with mineral oil will retain the oil for months even when exposed to sun and rain. The mixture of coal dust and oil is quite uninflammable. The experiment may perhaps be worth trying in one of the drier coal-mines.

December 27 R. RUSSELL

Geological Climates

PROF. DUNCAN is under the impression that the claim of *Araucaria Cunninghami* to have flourished at Bournemouth during the Eocene, rests on "a bit of a leafy part of a tree," and that this bit is "squashed." The foliage is however abundant there, occurring almost wherever vegetable remains are found, from the east of Bournemouth Pier to half a mile beyond Boscombe. In one place, where a bluff is literally full of it, the disarticulated branchlets are perfect, and not in the least degree compressed. Again, the determination was not made by Prof. Haughton, but rests upon my statement that this foliage and that of *A. Cunninghami* cannot be distinguished one from the other. That it is Araucarian foliage I am perfectly satisfied, but whether the existing Australian species is identical and unmodified, must remain doubtful until other

organs besides foliage are found, it being by no means absolutely certain that because the foliage is identical the species are so. The discussion raised by Prof. Haughton, and continued by Prof. Duncan and Mr Wallace, seems therefore hardly worth prolonging, since it is based upon an assumption that is only probably correct. But even if the identity were proved, a single species is not satisfactory evidence of former temperature

I am indebted to Mr Winslow Jones for the only information that I have yet obtained about the growth of either species in England. He recollects a small tree of *A excelsa*, growing near the water's edge in a garden on the upper portion of Falmouth Harbour, which he believes died three years ago. He has seen *flourishing trees* at Naples, Cintra, Malta, and Algiers, but even Northern Italy seems beyond the range of successful cultivation. Of the two *A Cunninghami* seems the more tender, though possibly its less symmetric growth may have excluded it from many gardens In Madeira it grows generally best close to the sea and in sheltered places.

Lindley was mistaken in regarding the two species as one. All the needle-leaved (Eutacta) section of Araucaria are certainly closely allied, for the species, however distinct in other respects, possess two kinds of foliage, that of the young plants being identical in all yet otherwise the species are clearly and distinctly marked off from each other.

With further regard to the identification of the Bournemouth foliage with Araucaria, I find that Massalongo[1] gives an excellent photograph of the same foliage from Chiavon, in North Italy, and of an immature cone consisting of 250 scales Although existing Sequoias have cones with from 16 to 20 scales, Schimper says "Il est sans aucun doute un *Sequoia* et peut être identique au *S. Sternbergii*. Les cônes ont la plus grande ressemblance avec ceux du *S gigantea*" (Pal. Végétale," vol III. p 573). I am beginning to lose all faith in the so-called science of palæo-botany as worked out by our Teutonic brethren Not only is the above quotation an absurdity, for which Heer is responsible, but I fail to see any good evidence to support the change made by Heer from *Araucaria*[2] *Sternbergii* to *Sequoia Sternbergii*. The foliage is more Araucaria like than Sequoia-like, and has been found associated with an Araucaria cone, but never with any Sequoia cones It has nothing to do with the Icelandic foliage, neither with the Upper Miocene foliage from Turin, nor that from Bilin nor Oeningen. The true *Araucaria Sternbergii* characterises a well-marked horizon, that of the Newer Eocene or Oligocene in Central Europe, and has been found at Barton in Hampshire, it differs from the Middle Eocene form (*A venetus*, Mass) of England and Italy in the needle-like leaves hugging more closely to the branchlet, as the latter differs in its turn from the Araucaria of the Grès du Soissonnais, which has needles very widely opened out This progressive change may have taken place *pari passu* with the changing climate At Sheppey, where foliage is plentiful, I have met with a beautifully-preserved axis of an Araucaria cone with the basal scales attached, exactly as we find them in the existing species

Now with regard to Mr. Wallace's letter, I pointed out in NATURE, vol xix p 126, that the Tertiary fossil plants, even of the Eocene, require at most an increase in temperature of 20°, and that the land connection between Europe, Greenland, and America, which there is reason to suppose existed then, would, by shutting out Arctic currents, have produced more than the required increment If this theory appeared for the first time in my article, however clumsily I may have worded it, and if it has been of use to Mr Wallace, it is only fair that the fact should be acknowledged, while if it has escaped his notice he will perhaps pardon my now drawing his attention to it At the same time the publication of the Tertiary flora of North-East Siberia, which I had not then seen, and of Saghalien, has modified the views I put forward in a manner which I trust I may shortly find time to explain.

J. STARKIE GARDNER

Chalk

MR. WALLACE's theory that chalk was deposited in comparatively shallow water requires careful examination before it is accepted by geologists I do not think he has given sufficient evidence to bear out his views which are necessary to his theory of continents.

Mr Wallace cites the resemblance between chalk and Globigerina-ooze, namely—

The similarity of the minute organisms found to compose a considerable portion of both deposits; several species of Globigerina appearing to be identical in the chalk and the modern Atlantic mud; the presence of Coccoliths and Discoliths in both formations, the abundance of Sponges in both; the presence of *Porifera vitrea*, the nearest representative of the Ventriculites of the white chalk, the resemblance of the forms of Echinoderms, and without attempting to reconcile these with a shallow sea-deposit, he proceeds to state the case on the other side. This consists of the difference in analysis between chalk and Globigerina-ooze, the former containing more carbonate of lime and less alumina, the presence of silica in the Globigerina-ooze being perhaps counterbalanced by the flints in the chalk. The greater proportion of alumina certainly points to different conditions, which Mr. Wallace considers to be that chalk is the very fine mud produced by the disintegration of coral-reefs, and mentions a deposit resembling chalk at Oahu in the Sandwich Islands and the deposit in several growing reefs, without however attempting to show that there is any probability that the remains found in these would bear any resemblance to the Sponges and Echinoderms of the chalk, or why we find no remains of these Cretaceous coral-reefs.

Mr. Wallace does not state in what the greater resemblance between chalk and Globigerina-ooze of shallow over deep water consists, but he looks on it as "weighty evidence."

Mr. Gwyn Jeffries, he says, finds all the Mollusca of the chalk to be shallow-water forms, many living at forty to fifty fathoms, some confined to still shallower waters, while deep sea forms are absent. The late Dr. S P Woodward considered that Ammonites probably lived in water not over thirty fathoms; and these facts are as difficult to reconcile with Mr Wallace's views that chalk was deposited in a sea of not over a few thousand feet as in a deeper sea.

The rareness of corals and absence of coralline beds of the age of the Lower or Upper Chalk is an important objection to the theory that chalk was deposited similarly to the Oahu chalk, the beds of Maestricht and Faxoe being above the chalk, and the former are not even conformable with it

The point I think is still an open one, whether we shall accept Mr. Wallace's views that chalk was deposited in a comparatively shallow sea and not very far from land, or in a deep sea, the immense break between the chalk and Eocene beds giving ample time for very considerable alteration to have taken place in the disposition of land in the interval. I send this letter in the hope that a discussion on the point may elicit new facts bearing on the subject.

S. N CARVALHO, JUN.

On Estimating the Height of Clouds by Photography and the Stereoscope

THE great practical value of meteorological science and the desirability of extending its usefulness by the collection of data relating to atmospheric current will perhaps be sufficient excuse for asking attention to anything likely to promote this end.

In studying the currents and other peculiarities of the atmosphere a method of estimating the height, motion, and character, as also the position with respect to each other, of each stratum of cloud, is a requirement of almost paramount importance, the value of the means employed being proportional to the number of particulars provided in its record, and the facility with which any set of observations can be compared to another at any future period. With such ever-changing subjects as clouds in constant motion, and having no strongly-defined marks, the use of theodolites is almost out of the question, and the sextant and mirror process for similar reasons would be a very tedious operation.

These considerations have induced me to endeavour to make use of photography and the stereoscope, the former to secure a couple of simultaneously-exposed photographs at the extremities of a base line, and the latter to observe them reproduced apparently solid for the respective distances of the points composing the picture to be measured when superimposed on a scale of distances and placed in it. The base line is thus practically reduced to the width of the eyes, and the difficulties arising from motion eliminated

The recording apparatus consists of a base 50 or 100 feet long, constructed of wood and turning on a pivot at the centre of its length, its extremities being suitably supported by a framework of wood or other material upon which they could easily roll. The small cameras for the ends of this are each to be hinged at the back of its base to a second board having a graduated quadrant and rackwork erected from one of its sides for adjusting

[1] "Specimen photographicum" Verona, 1859 Plate xxi

[2] Actually described as Araucarites, a useless modification in this instance.

the camera to any degree of altitude. These supplementary boards are then pivoted at the centre of part of a divided circle, previously inlaid in the wood at the extremities of the base line, in such a manner that a line passing through the axis of the lenses would cut the pivots. The cameras thus furnished can be adjusted with ease to any vertical or horizontal angle. These angular adjustments of the two instruments must always coincide, with the slight exception that the horizontal ones must make internal angles with the base included between them, or, in other words, the lenses of both require to be directed to a point opposite to the centre of the base line.

The cameras also require their rapid exposing shutters to be electrically connected, to ensure the pair of sensitive plates being impressed at the same instant, and each dark slide employed to have a fine wire strained at its centre from top to bottom immediately in front of the prepared plate, and as close as possible to it without touching. The transparent lines produced in the developed negatives by these wires will constitute the zero of distance of any pair, and during the operation of reading off must be made to agree with similar ones on the scale of measurements obtained as follows:—

Upon a large cardboard rule a number of squares in fine black lines, one inside the other, and each one slightly out of the centre of its predecessor to the right hand, the outside square being then divided with a line at a tenth part of its diameter to the left of its centre. This line will indicate the zero of the scale. After placing a distinguishing mark or number in the corner of every square for purposes of identification, the cardboard will be ready to be photographed and reduced at the same time to the intended size of the cloud negatives. Two transparent positives copied from this and observed when placed side by side in a suitable stereoscope with the edges representing the left-hand one of the cardboard together, will appear in that instrument with the lines composing the zero only a few inches away, and the squares as a succession of vertical planes commencing some distance from that and receding from the eye in the order of greater to less, each one representing its own distance in space.

To find the value of these distances it will be necessary to focus the two cameras upon some terrestrial objects whose distances can be measured by any of the known methods, and negatives taken. The two resulting landscapes, when placed in the stereoscope, each superimposed face to face upon its respective scale, and the fine vertical lines of the whole made to occupy one apparent distance, an operation offering but little difficulty, every object or point of the landscape will be found to stand out in the vertical plane suited to its own distance, the relation between them being noted for the values found by measurement of the one to be marked upon the other. As a scale prepared thus would be of no value for any other angle at which the cameras might be placed, it would be most convenient to make use of two or three angles only, more being quite unnecessary, and prepare a scale for each, or one with a reference table of values for the respective angles would suffice. Again, in respect of altitudes: As the terrestrial measurements would only be absolutely accurate for those of clouds in the zenith, or of them, if it were possible, from the earth's centre in any direction, the tables of reference would have to include calculated corrections for altitude, or the graduations could be valued for the most useful degrees by experimental means.

It will be gathered from the above that the constancy of length of the base line can be ascertained, and corrected if necessary, by taking a couple of views of the same landscape for comparison with the preceding pair; slight fluctuations of length would not however be of much consequence in dealing with the comparatively coarse measurements of thick masses of cloud floating in so short a distance as the few miles of atmosphere capable of forming them consists.

To ascertain the height of clouds photograph a pair of negatives, and place these in the stereoscope with a pair of scale plates agreeing with the angle at which they were taken, and adjust as for the landscapes described above. The data required may then be read off by noting the vertical plane each stratum occupies.

Prints of these negatives should afterwards be made for the particulars of height, direction of motion of the respective layers, point of compass, wind rate, state of barometer, thermometer, and general remarks upon the weather, to be recorded upon them for comparison or circulation.

Meteorological observatories fitted with such an addition to their present splendid collection of instruments would have their powers of dealing with the atmosphere and weather changes greatly reinforced JOHN HARMER

Wick, near Arundel

Correction of an Error in "Island Life"

MY friend Dr. Gunther has kindly called my attention to an extraordinary error at p. 322–323 of my "Island Life," where I state that the Loch Killin Charr (*Salmo Killinensis*) inhabits a lake in Mayo County, Ireland, instead of a small lake in Inverness-shire, 2000 feet above the level of the sea, as given in Dr. Gunther's original description in the *Proceedings* of the Zoological Society, 1865, p. 698. On referring to my MSS. notes for this part of my work, I find that the habitat was first correctly given, but subsequently scored out and altered to the erroneous Irish locality! Why this was done I cannot now discover, and I can only regret that I should have fallen into so palpable an error, and request such of the readers of NATURE as possess my book to make the necessary alterations.

ALFRED R. WALLACE

Natural Science for Women

WILL you allow me to supplement your kindly reference to the instruction in physical science given to women in Bedford College, London, by the statements that for the last two sessions a class in biology has been conducted there by Mr. Charles Stewart of St. Thomas's Hospital Medical School. The course of study is in every sense a practical one, with special reference to the Preliminary Scientific and First B.Sc. examinations at the University of London, and the best testimonial to the excellence of the instruction in these various subjects is furnished by the remarkable success during the present year of the Bedford College pupils at the University examinations, a success not less marked in the Science than in the Arts examinations.

ALFRED W. BENNETT

Movements of Leaves

A YEAR ago we had in our conservatory a healthy young plant of *Acacia mollissima*. It bore no flowers, but consisted of a simple axis adorned with the soft feathery leaves of its genus, which closed up at night. Our gardener however thought it would improve in appearance if it could be made to bear a few branches, and with that view he cut it back. His end was achieved: a new stem shot up from the section, and graceful limbs were thrown out in turn by it. But along with this a strange result followed: the fresh leaves borne by the new stem and by the branches now closed at night, while the old leaves below the section ceased to do so. These lower leaves have long since fallen off, but the upper ones kept to their habit, and at the present time all fold up at dusk save a few of the very oldest, which only partially shut, or, in one case, do not shut at all. When our plant was cut back it stood three feet high, now it stands seven: which shows that the vigour of the plant as a whole in no wise diminished by the operation.

Chislehurst, December 23 M. L. ROUSE

ON DUST, FOGS, AND CLOUDS[1]

DUST, fogs, and clouds seem to have but little connection with each other, and we might think they could be better treated of under two separate and distinct heads. Yet I think we shall presently see that they are more closely related than might at first sight appear, and that dust is the germ of which fogs and clouds are the developed phenomena.

This was illustrated by an experiment in which steam was mixed with air in two large glass receivers; the one receiver was filled with common air, the other with air which had been carefully passed through a cotton-wool filter and all dust removed from it. In the unfiltered air the steam gave the usual and well-known cloudy form of condensation, while in the filtered air no cloudiness whatever appeared. The air remained supersaturated and perfectly transparent.

The difference in the behaviour of the steam in these two cases was explained by corresponding phenomena,

[1] Abstract of a paper read to the Royal Society of Edinburgh, December 20, by Mr. John Aitken. Furnished to NATURE by the Council of the Society.

in freezing, melting, and boiling. It was shown that particles of water vapour do not combine with each other to form a cloud-particle, but the vapour must have some solid or liquid body on which to condense Vapour in pure air therefore remains uncondensed or super-saturated, while dust-particles in ordinary air form the nuclei on which the vapour condenses and forms fog or cloud-particles

This represents an extremely dusty condition of the air, as every fog and cloud-particle was formerly represented by a dust-particle, which vapour by condensing upon it has made visible When there is much dust in the air but little vapour condenses on each particle, and they become but little heavier, and easily float in the air If there are few dust specks each gets more vapour, is heavier, and falls more quickly

These experiments were repeated with an air-pump, a little water being placed in the receiver to saturate the air The air was then cooled by slightly reducing the pressure. When this is done with unfiltered air a dense cloudiness fills the receiver, but when with pure air no fogging whatever takes place, there being no nuclei on which the condensation can take place In this experiment, and in the one with steam, the number of cloud-particles is always in proportion to the dust present When the air is nearly pure and only a few dust-particles present, then only a few cloud-particles form, and they are heavy and fall like fine rain.

The conclusions drawn from these experiments are (1) that whenever water vapour condenses in the atmosphere it always does so on some solid nucleus, (2) that dust-particles in the air form the nuclei on which the vapour condenses, (3) that if there was no dust there would be no fogs, no clouds, no mists, and probably no rain, and that the supersaturated air would convert every object on the surface of the earth into a condenser on which it would deposit, (4) our breath when it becomes visible on a cold morning, and every puff of steam as it escapes into the air, show the impure and dusty condition of our atmosphere

The source of the fine atmospheric dust was then referred to, and it was shown that anything that broke up matter into minute parts would contribute a share The spray from the ocean, when dried and converted into fine dust, was shown to be an important source Meteoric matter also probably contributed a proportion Attention was then directed to the power of heat and combustion as a source of this fine dust.

It was shown that if there is much dust then each particle only gets a little vapour condensed upon it, that when the particles are numerous they become but little heavier, and easily float in the air, and give rise to that close-packed but light form of condensation which constitutes a fog, and therefore whatever increases the amount of dust in the air tends to increase fogs, and that when the dust-particles are not so numerous the cloud-particles are larger and settle down more quickly.

It was shown that by simply heating any substance, such as a piece of glass, iron, brass, &c, a cloud of dust was driven off, which, when carried along with pure air into the experimental receiver, gave rise to a dense fog when mixed with steam So delicate is this test for dust that if we heat the one-hundredth of a grain of iron wire the dust driven off from it will give a distinct cloudiness in the experimental receiver, and if we take the wire out of the apparatus and so much as touch it with our fingers and again replace it, it will again be active as a cloud-producer. Many different substances were tried, and all were found to be active fog-producers. Common salt is perhaps one of the most active

Heat, it is well known, destroys the motes in the air, and it might be thought that flame and other forms of combustion ought to give rise to a purer air. Such however is not the case. Gas was burned in a glass receiver, and supplied with filtered air for combustion, and it was found that the products of combustion of pure air and dustless gas gave rise to an intensely fog-producing atmosphere It may be mentioned here that the fog-producing air from the heated glass, metals, and burning gas were each passed through the cotton-wool filter, and the air was in all cases made pure, and did not give rise to cloudiness when mixed with steam

It will be seen that it is not the dust motes which are revealed to us by a beam of sunlight when shining into a darkened room, that form the nuclei of fog and cloud-particles, as these may be entirely removed by heat, and yet the air remain active as a cloud-producer. The heat would seem to break up the larger motes which reflect the light into smaller and invisible ones When speaking of dust, it is to these infinitesimally small and invisible particles we refer. The larger motes which reflect the light will no doubt be active nuclei, but their number is too small to have any important effect.

It is suggested, and certain reasons are given for supposing, that the blue colour of the sky is due to this fine dust.

Other experiments were made to test the fog-producing power of the air and gases from different sources The air to be tested was introduced into the experimental receiver and mixed with steam, and the relative densities of the fog produced were noted It was always found that the air of the laboratory where gas was burning gave a denser fog than the air outside, and that the air outside varied, giving less fog during wet than during dry weather. The products of combustion of gas burned in a Bunsen flame, a bright flame, and a smoky flame, were all tested and found to be about equally bad, and all much worse than the air in which they were burned. Products of combustion from a clear fire and from a smoky one gave about equal fogging, and both much worse than the air of the room.

Experiments were made by burning different substances. Common salt when burned in a fire or in alcohol flame gave an intensely fog-producing atmosphere, but burned sulphur was the most active substance experimented on It gave rise to a fog so dense it was impossible to see through a thickness of 5 cm of it

The vapours of other substances than water were tested to see if they would condense in the cloud form without nuclei on which to deposit All the substances experimented on, which included sulphuric acid, alcohol, benzole, and paraffin, only gave a cloudy condensation when mixed with ordinary unfiltered air, and remained perfectly clear when mixed with filtered air, all these acting like water vapour

Before referring to fogs, which have now become so frequent and aggravated in our large towns, it was pointed out that caution was necessary in applying the results of the experiments

The conditions of a laboratory experiment are so different, and on so small a scale, that it is not safe to carry their teaching to the utmost limits and apply them to the processes which go on in nature. We may, however, look to the experiments for facts from which to reason, and for processes which will enable us to understand the grander workings of nature.

It having been shown that vapour, by condensing on the dust-particles in the air, gives rise to a fogging, the density of which depends on the amount of fine dust in the air, the more dust the finer are the fog-particles, and the longer they remain suspended in the air. It having been also shown that all forms of combustion, perfect and imperfect, are producers of fog nuclei, it is concluded that it is hopeless to expect that, adopting more perfect forms of combustion than those at present in use, we shall thereby diminish the frequency, persistency, or density of our town fogs More perfect combustion will, however, remove the pea-soup character from the fogs

and make them purer and whiter, by preventing the smoke which at present mixes with our town fogs and aggravates their character, and prevents them dissolving when they enter our rooms Smoke descends during a fog, because the smoke particles are good radiators, and soon get cooled and form nuclei on which the water vapour condenses. The smoke thus becomes heavier and falls. This explains why falling smoke is often a sign of coming rain It indicates a saturated condition of the atmosphere

Sulphur when burned has been shown to be an intensely active fog-producer. Calculation shows that there are more than 200 tons of sulphur burned with the coal every winter day in London, a quantity so enormous as quite to account for the density of the London fogs It is suggested that some restriction ought to be put on the amount of sulphur in the coal used in towns

Before utterly condemning the smoke and the sulphur, it was pointed out that it would be necessary thoroughly to investigate and fully to consider the value of smoke as a deodoriser, and also the powerful antiseptic properties of the sulphurous acid formed by the burning sulphur The air during fogs is still and stagnant There is no current to clear away the foul smells and deadly germs that float in the air, which might be more deadly than they are, were it not for the suspended soot and burned sulphur We must therefore be on our guard lest we substitute a great and hidden danger for an evident but less evil.

ON THE SPECTRUM OF CARBON

ALTHOUGH fifteen years have passed since the possibility of one substance possessing more than one spectrum was first suggested by Plucker and Hittorf, the question of the existence of double spectra cannot yet be considered as decided One of the elements to which multiple spectra have been attributed is carbon, which was at one time supposed to possess four different spectra of these one has been shown to be due to oxide of manganese, a second to oxides of carbon, the origin of a third (obtained only from oxides of carbon) has hardly been discussed (though it may prove to be one of the true carbon spectra), and the other "carbon" spectrum—the best known of all—is the one first attributed to carbon by Attfield, but ascribed to acetylene by Angstrom

In a paper read before the Royal Society, and of which an abstract is given in NATURE, vol xxii p 620, Professors Liveing and Dewar describe experiments to prove that this spectrum is that of a hydrocarbon, and not of carbon itself, and also that certain blue bands, best seen in the flame-spectrum of cyanogen, are due to compounds of carbon and nitrogen, and not to carbon itself. They attribute to hydrocarbon (amongst others) the yellowish-green group, which we will call γ, of wave-lengths from about 5635 to 5478, and the emerald-green group, which we will call δ, of wave-lengths from about 5165 to 5082, and they attribute to nitro-carbon the two blue groups of wave-lengths 4600 to 4502 and 4220 to 4158, which we will call θ and ζ respectively

As these result are directly opposed to my own experience, I have thought it necessary to repeat two of the experiments described in my paper on the carbon spectra in the *Philosophical Magazine* for October, 1869, under such conditions as to exclude (as far as lay in my power) all trace of hydrogen in the one case, and of nitrogen in the other

The difficulty of supposing carbon to be present in the state of vapour at any temperature which we can command seems to be the chief reason why so many investigators think it necessary to attribute the spectrum in question (with experimental evidence or without it) to compounds of carbon I am not aware that Ångström ever gave any experimental proof of his assertion that this spectrum was caused by acetylene

On the other hand, the evidence that the spectrum is due to carbon is that first stated by Attfield, that if these lines "are absent in flames in which carbon is absent, and present in flames in which carbon is present," if they are "observable equally in the flame of the oxide, sulphide, and nitride as well as in the hydride of carbon," and if "present whether the incandescence be produced by the chemical force, as in burning jets of the gases in the open air or by the electric force, as when hermetically-sealed tubes of the gases are exposed to the discharge of a powerful induction-coil," then they "must be due to incandescent carbon vapour" , and if this is borne out by experiment the conclusion that the lines are due to carbon (as gas, liquid or solid) cannot be resisted, whatever may be the apparent impossibility of volatilising or even liquifying carbon, even by the most powerful current of electricity directed through it

We must bear in mind how very small a quantity of a gas is often sufficient to give us a spectrum, and when the carbon spectrum is obtained by the decomposition of olefiant gas or cyanogen by passing sparks through the gas, the carbon certainly exists as gas in the compound which is decomposed, and before the liberated atoms unite together to form the molecules of the solid, there is surely no impossibility in their existing for the moment as gas—as gaseous carbon

On an examination of Professors Liveing and Dewar's paper to ascertain the experimental evidence upon which the bands γ and δ are attributed to hydrocarbon and not to carbon itself, we find it stated that "the green and blue bands characteristic of the hydrocarbon flame seem to be always present in the arcs, whatever the atmosphere. This is what we should expect if they be due, as Angstrom and Thalén suppose, to acetylene, for the carbon electrodes always contain, even when they have been long heated in chlorine, a notable quantity of hydrogen"

Since then it is impossible to completely expel hydrogen from the carbon-poles, we must reject all the experiments in which the electric arc was observed in atmospheres of different gases, although "the green and blue hydrocarbon bands were seen more or less in all of them"

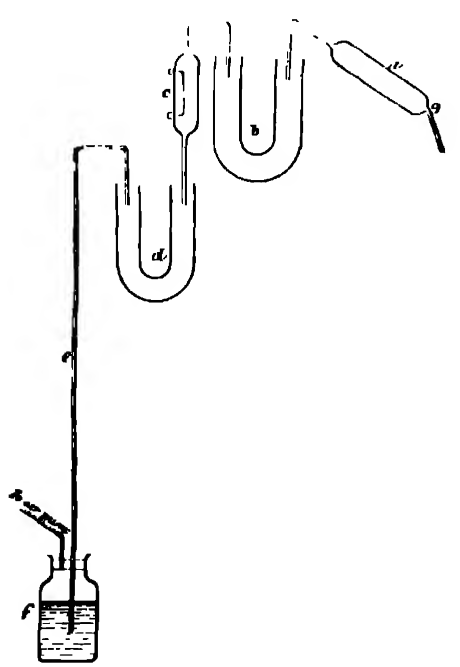
Turning then to other methods of producing the spectrum, we find it stated that in the flame of carefully-dried cyanogen "the hydrocarbon bands were almost entirely absent" (they should have been *entirely* absent), "only the brightest green band was seen, and that faintly." Hence we are to infer, I suppose, that the bands γ and δ, so brilliant in the flame of cyanogen in air or oxygen, are due to the accidental presence of hydrogen (see the extract from Moiren's paper, NATURE, vol. xxii p 7 Dibbits also speaks of this spectrum as "by far the most magnificent" he has seen)

Next we have the experiment of burning hydrocyanic acid, in which, as we have hydrogen present, we expect to find the hydrocarbon bands brilliantly developed But we find the result stated as "very much the same as that of cyanogen" The flames of hydrogen and sulphide of carbon, and of hydrogen and carbonic oxide, do not give the hydrocarbon bands (their spectra being continuous), a mixture of hydrogen and carbon tetrachloride gives them faintly, and a mixture of hydrogen and chloroform gives them strongly

In all this we have no *proof* of the point in question, nor even any special probability that the bands are due to hydrocarbon , and yet, in the face of experiments in which the spectrum is obtained from cyanogen, when care has been taken to exclude hydrogen, we are asked to attribute the bands to the hydrocarbon formed by combination with some trace of hydrogen (as water or otherwise), supposed to be present as impurity. In the same way the presence of the bands θ and ζ obtained under circumstances when nitrogen has been intentionally excluded, is to be explained by "the extreme difficulty of

removing the last traces of air." So that in the case of cyanogen with a trace of hydrogen present, the spark persists in giving us the spectrum of hydrocarbon; and when we have naphthalin with a trace of nitrogen present, it gives us the spectrum of nitrocarbon!

Attfield states that the spectrum in question is obtained from *pure dry* cyanogen. "The ignition of the gases having been effected in air, it was conceivable that hydrogen, nitrogen, or oxygen had influenced the phenomena. To eliminate this possible source of error the experiments were repeated out of contact with air. A thin glass tube one inch in diameter and three inches long, with platinum wires fused into its sides and its ends prolonged by glass quills having a capillary bore, was filled with *pure dry* cyanogen, and the greater portion of this gas then removed by a good air-pump. Another tube was similarly prepared with olefiant gas. The platinum wires in these tubes were then so connected with each other that the electric discharge from a powerful induction-coil could pass through both at the same time. On now observing the spectra of these two lights in the simultaneous manner previously described, the



characteristic lines of the hydrocarbon spectrum were found to be rigidly continued in that of the nitrocarbon. Moreover, by the same method of simultaneous observation the spectrum of each of these electric flames, as they may be termed, was compared with the corresponding chemical flames, that is with the oxyhydrocarbon and oxynitrocarbon jets of gas burning in air. The characteristic lines were present in every case."

"The spectrum under investigation having then been obtained in one case when only carbon and hydrogen were present, and in another when all elements but carbon and nitrogen were absent, furnishes to my mind sufficient evidence that the spectrum is that of carbon."

Morren also adopted this method of producing the spectrum by taking the spark of an induction coil in a sufficiently rapid current of pure cyanogen at atmospheric pressure.

I have again repeated this experiment with cyanogen under conditions which would seem to ensure that the gas should be dry (see also *Phil Mag*, 1875).

The cyanogen was prepared by heating pure cyanide of mercury, which was finely powdered and placed in a piece of combustion-tubing (*a*) drawn out at both ends. In this it was repeatedly heated to the temperature of incipient decomposition whilst a current of dry air was drawn over it. One end of the tube was then closed by fusion at the point *g*, and the other bent round and fitted, as shown in the figure, to a U-tube (*b*) containing phosphoric anhydride—the discharge-tube *c* was interposed between this U-tube and a second U-tube *d* also containing phosphoric anhydride, the other branch of which was connected to one end of a vertical tube *e* of more than thirty inches in length, the lower end of which passed into mercury contained in the bottle *f*, the upper portion of which could be exhausted by means of the air-pump. The connections with the U-tube were made by means of perforated india-rubber stoppers, and the joints were surrounded during the experiment by melted paraffin.

The apparatus having been exhausted, the mercuric cyanide was heated till the apparatus was filled with cyanogen at atmospheric pressure, it was then again exhausted and again filled with cyanogen. After having been thus exhausted and re-filled five or six times, the spectrum of the spark between the wires at *c* was examined at various pressures. The spectrum figured in my paper in the *Philosophical Magazine* for October, 1869, was obtained, the groups γ and δ, with which alone we are at present concerned, being the brightest in the whole spectrum. Next careful search was made for the red hydrogen line. The cross-wires of a one-prism spectroscope were accurately adjusted to the red line, as seen in a hydrogen vacuum tube, and the spectroscope was then directed upon the spark in the cyanogen. No trace of the line could be observed.

A second experiment was devoted to the examination of the spark in an atmosphere of naphthalin vapour, from which nitrogen had been excluded as far as possible, in order to ascertain whether the bands ζ and θ, which Professors Liveing and Dewar attribute to cyanogen, would be produced. Professors Liveing and Dewar are somewhat in error in saying that I laid much stress on the occurrence of these bands in carbonic oxide. They were never obtained very brilliantly from carbonic oxide (except under pressure), but they are obtained brilliantly from a naphthalin vacuum tube. I have obtained them also from a vacuum tube containing pure marsh-gas (my note-book remarks "θ very bright"), and as confirmation by an independent observer, I would remark that Plucker maps them in the spectrum of a vacuum tube containing *methyl*.

The vacuum tube in this second experiment contained pure solid naphthalin fused on the sides of the tube, this was placed in position so that the upper end passed through one hole in an india-rubber stopper into a flask filled with carbon dioxide, a vertical tube of thirty inches length passed through the second hole in the stopper of the flask, and its lower end dipped below mercury. The whole of the vacuum tube except the lowest portion was surrounded by a wider tube containing melted paraffin.

When the apparatus had been arranged, the experiment was commenced by passing a rapid current of carbonic acid through the vacuum tube, so as to fill the flask and escape through the mercury. After passing the gas for a considerable time, the lower end of the tube was closed by fusion, the naphthalin all melted down into this end, where it was made to boil violently, while the paraffin was maintained at a temperature of about 220° C. After the current of naphthalin vapour had lasted some time, the upper end of the tube was closed by fusion, the tube removed and cooled, and its spectrum examined. It gave a spectrum in which the groups ζ and θ were plainly seen.

It is to be hoped that some independent observer will repeat these experiments, so as finally to settle the question of the origin of these bands of what I must still call the "carbon" spectrum. W. M. WATTS

THE INDO-CHINESE AND OCEANIC RACES—TYPES AND AFFINITIES

I

THE ethnological area here under consideration comprises the south-eastern corner of the Asiatic mainland, and nearly the whole of the Indian and Pacific Oceans. Of the three great divisions of the human family—the black, yellow, and fair—the two former alone are usually supposed to be represented in this region, the black by the Australians, extinct Tasmanians, Melanesians or Papûans, and Negritos, the yellow by the Indo-Chinese (Annamese, Siamese, Burmese, &c.), of the mainland, and the so-called "Malayo-Polynesians" of Oceanica. But it will be one of the main objects of these papers to show that room must here be henceforth made for the third also, and that most of the difficulties associated with the mutual classification of the other two are due to the omission or neglect of this third factor in the problem. It has long been an accepted doctrine of ethnologists that this fair or Caucasian type, using the term "Caucasian" in Blumenbach's sense, is limited by some mysterious law of nature or providential arrangement to the western portion of Asia, to the northern section of its African, and to nearly the whole of its European peninsula. But anthropology is a very young science, and as facts accumulate and knowledge expands, many of its conclusions too hastily arrived at will have to be modified or abandoned. The time seems to have already arrived for very materially modifying the views hitherto entertained regarding the geographical limits of the Caucasian species, which, instead of being confined to a western corner of the Old World, will be found to have been diffused in prehistoric times eastwards to within 2,500 miles of the American continent.

But the acceptance or rejection of this new doctrine will of course depend largely on the various senses in which the terms type, species, race, are understood by the different monogenist and polygenist schools. For the orthodox monogenist these words can obviously have but a relative meaning, for if all are necessarily sprung of one created pair, all have also necessarily become differentiated into the now existing types, these types thus sinking to the category of mere varieties. But to polygenists of all shades such expressions may naturally convey an absolute sense, the fundamental species now existing having presumably been evolved in so many independent centres, and for these the only question will be in *how many* centres? Yet even they cannot consistently base their theory on the eternal fixity of species, for they are all of them otherwise, and necessarily believers in evolution. They must therefore admit the abstract possibility of such comparatively slight transformism as the development of the dark from the yellow, the fair from either, lank from woolly hair, dolichocephaly from brachycephaly, the tall stature of the Tehuelch Patagonian from the pygmy Akka, or the reverse of all these processes. They may say that, assuming independent development from various anthropoids, such transformism is unnecessary to account for the present state of things, but they can never deny its inherent possibility, for it still remains a very trivial modification compared with the evolution of any given human from any given anthropoid type. Nor will they deny that in general differentiations of this sort are far more easy and explicable than independent growths, which involve so much more fundamentally radical changes. Consequently unorthodox monogenism, that is monogenism not starting from a created pair, but from one evolutionary centre, seems more rational and philosophic than any conceivable form of polygenism. This view seems in other respects to harmonise best with the actual conditions, and an effort has accordingly been made to give it expression in the subjoined definition of species, which differs in some important respects from those hitherto proposed. *Species is an aggregate of units resembling each other in all salient points, producing offspring of the same type in the same surroundings, or of continuously modified type in continuously modified surroundings, and themselves evolved of previous species similarly modified indefinitely.* Thus any given species or race (terms practically identical when used with scientific precision) exists only for the time being, is not and cannot be permanent, for it has become what it is by slow modification under slowly modified outward conditions, has had a beginning, may have an end. The best vindication of this truth is the geological record, which can only be explained either with Cuvier by the unwarranted assumption of successive fresh creations, or with common sense by regarding type or species as relative, not absolute concepts. Between the two views there seems to be no logical middle term.

It is therefore in this relative sense only that race or species are here to be understood, and in this sense it will be seen that all the three most fundamental types of mankind have existed from the remotest times in the wide area above defined. With their diverse modifications and intercrossings these three types form altogether seven main groups, which it will be convenient to take *seriatim* in the order adopted in the subjoined

General Scheme of Indo-Chinese and Oceanic Races

A.—DARK TYPES

I. NEGRITOS. Aetas, Andamanese, Samangs, Kalangs; Karons.

II. PAPÛANS.
- Central branch—Papûans Proper.
- Western branch—Sub-Papûans West (so called "Alfuros").
- Eastern branch—Sub-Papûans East (Melanesians).

III. AUSTRAL. Australians, Tasmanians (?)

B.—CAUCASIAN TYPE (Fair and Brown)

IV. CONTINENTAL BRANCH. Khmêr or Cambojan Group.

V. OCEANIC BRANCH. Indonesian and Sawaiori or Eastern Polynesian Groups.

C.—MONGOLIAN TYPE (Yellow and Olive Brown)

VI. CONTINENTAL BRANCH. Indo-Chinese Group.

VII. OCEANIC BRANCH. Malayan Groups.

A.—DARK TYPES

I. THE NEGRITOS. *Aetas, Andamanese, Samangs; Kalangs, Karons.*

Of the three divisions of this type shown in our scheme the Negrito is probably the most primitive. It seems to have formed the aboriginal element in South-East Asia and Malaysia at a time when the Archipelago was still connected with the mainland, but it is now represented only in a fragmentary way by the wild tribes in the Philippines collectively known as Aetas, Aitas, or Itas, the so-called "Mincopies" of the Andaman Islands, the little-known Samangs of Malacca, probably the Karus or Karons[1] of the Arfak Hills behind Geelvink Bay, New Guinea, and a few surviving members of the Kalangs of East Java. From a number of specimens recently brought to Europe, the osteology of the Aetas and Andamanese has been carefully studied, the former by Virchow in Germany, the latter by Prof. Flower in England, with parallel and in many respects identical results. Virchow[2] describes the Aetas as "a brachycephalous race differing altogether from the Papuans and Australian Negroes, and no less so from the African Negroes." He adds that they are "strongly prognathous," the profile of some

[1] Described by M. Raffray ("Tour du Monde," April 26, 1879) as essentially distinct from the Papûans. "Ce ne sont pas des Papous, mais bien des Negritos plus semblables aux sauvages aborigènes des Philippines qu'aux Papous Mélanésiens qui les entourent."

[2] In "Correspondenz-Blatt der deutschen Gesellschaft für Anthropologie," &c. 1872, p. 58.

crania consequently presenting an almost "orang-utan physiognomy." So also Prof. Flower[1] tells us that the Andamanese cranium is "as distinct as possible" from the Melanesian, and on all the available evidence he seems disposed to regard these islanders as "representing an infantile, undeveloped or primitive form of the type from which the African Negroes on the one hand, and the Melanesians on the other . . . . may have sprung." The relations of the Negritos to the Papûans, long a vexed question in anthropology, may thus be regarded as finally settled by the most competent authorities. One

Fig. 1.—Ape-like Type, Java. Ardi of Buitenzorg.

doubtless, originally, they must now be regarded as two distinct species in the relative sense involved in our definition of that term. C. Staniland Wake also points out another important feature in which the two races differ. The Papûans proper, and especially the Melanesians of Fiji, New Caledonians and Solomon Islanders, are frequently furnished with well-developed beards, whereas the Andamanese and all other true Negritos, are absolutely beardless. "The absence of the beard seems to be characteristic of all the Negrito peoples, and this trait may in my opinion be safely added to the con-

clusions of de Quatrefages touching the small black races of the Archipelago."[2]

The ape-like appearance of the Aetas, already spoken of by de la Gironnière, and now insisted on by Virchow, receives a startling illustration from the accompanying portrait (Fig. 1) of a Javanese Kalang named Ardi, recently if not still employed as a workman in the famous Buitenzorg (Sans-Souci) Botanic Gardens near Batavia. Here he was seen by C. B. H. von Rosenberg in 1871, and reproduced at p. 569, vol. iii. of that naturalist's work on the "Malay Archipelago" from an original photograph by van Musschenbroek, which has also been

Fig. 4.—Full-blood Papûan Type. North-west Coast New Guinea.

figured on an enlarged scale in Dr. A. B. Meyer's monograph on the "Kalangs of Java." Notwithstanding its startling ape-like appearance all doubt as to the correctness of the portrait is removed by the independent testimony of von Rosenberg and van Musschenbroek, the latter of whom informs me through Prof. Veth of Leyden

Fig. 5.—Full-blood Papûan Type. North-west Coast New Guinea.

(Letter, October 16, 1880), that "he has met with the same type in other parts of Java, though not so pronounced, and that it could always be traced to a Kalang origin." He adds that "this race is fading away and that the intermixture with Common Javanese has become

[1] In paper "On the Osteology and Affinities of the Natives of the Andamanese Islands," in *Journal* of Anthropological Institute, November, 1879, pp. 132-3.

such that in most instances only faint traces of the peculiar type have been left." Meyer agrees with van Musschenbroek in regarding the Kalangs as a remnant of the aborigines of Java, possibly allied to the other

FIGS 6, 7.—Malayo-Papûan Mixed Types. Body-guard of the Sultan of Ternate

Negrito peoples of the Archipelago, and "occupying Java before it was peopled by the Malays" Ardi had come from the eastern parts of the island, where a few still linger no longer as a distinct tribe, but dispersed, like Ardi himself, amongst the general population Hence

the reader will doubtless be glad to have this authentic specimen of perhaps the very lowest type of mankind, now all but extinct.

Our next illustration (Fig. 2) is that of an Andamanese Negrito in a mourning head-dress, from a photograph sent to Europe by Mr. Man, and originally published in the *Anthropological Journal*, vol vii (1877) p. 416. It presents a singular resemblance to an Australian woman (Fig. 3) also in mourning, reproduced in the same place

FIG. 9.—A Motu Youth.

from a picture in Angus' "South Australia Illustrated", (plate 51)

The Negrito and Hottentot hair is usually described as growing in separate woolly tufts, or, as Topinard puts it, "in little peppercorn masses, separated by bald spaces" In his "Genealogical Classification" of the Human

FIG. 10.—Maori Type

Races and Languages" Venzel Kriżhek revives the well-known classification of Friedrich Muller which makes this feature the basis of one of the main divisions of mankind, including the Hottentots, Papûans, and Negritos. Yet the phenomenon has absolutely no existence in nature. But such is the tenacity of errors of this sort that

it seems impossible to dispel the delusion, although, as Prof. Flower well remarks, "the report of a committee of the Paris Anthropological Society on the growth of the hair of a Negro in one of the hospitals of that city, published last year (1879) in the *Bulletin* of the Society, ought to set the question at rest for ever" It is curious that evolutionists should have discovered in man a trait which is characteristic of none of the anthropoids

The Negritos, whether those described by Jagor and Meyer in the Philippines, or those visited by E. H. Man in the Andaman group, are all alike socially on the lowest level They are all nomadic, though not pastoral, moving about from hill to hill, from coast to river-bank, in search of food or shelter from the weather or their enemies. They live on the fruits and roots of the tropical woodlands, on wild honey, snakes, frogs, fish, or such game as their feeble weapons (mostly spear and bow and arrow) are able to procure them Yet, although indolent and incapable of providing for the future, they do not lack intelligence, for their brain capacity (index No 74) is still immensely greater than that of the highest anthropoid ape The Aetas often acquire a knowledge of the neighbouring Tagalog and Bisayan (Malayan) dialects, and the speech of the Andamanese seems from Man's specimens to belong to a highly agglutinating type. They appear to have no shrines or idols of any sort, in this greatly differing from the Papuans, and their religious thought is limited to a blind awe or fear of the powers of nature, for them doubtless supernatural manifestations But our knowledge of their inner life is still far too restricted to pronounce very positively on these points The Negritos are not generally suspected of cannibalism, but the Karons of New Guinea are certainly addicted to the practice One of them, although quite a youth, admitted to M Achille Raffray that he had already eaten fifteen men, treating it as quite a matter of course They appear, however, to confine themselves to the bodies of their enemies slain in battle, and do not regard every stranger as so much "meat," like the Negroes of the Lualaba-Congo

II. THE PAPÛANS. *Papûans proper, Sub-Papûans West ("Alfuros"), Sub-Papûans East (Melanesians)*

The Papûan domain is entirely oceanic, stretching in its widest sense from the island of Floris, Malaysia, eastwards to Fiji (120° – 180° E long), and from about the equator southwards to New Caledonia, at this point approaching the Tropic of Capricorn In our scheme are shown three branches, a central, western, and eastern, which grouping has the convenience of being at once geographical, and to a large extent ethnical The type itself, so named from the Malay word پُپُوَه (*papûwah* = frizzly), denoting one of its most striking characteristics, retains everywhere a considerable degree of uniformity in all essentials. But it is largely mixed with two distinct elements, the Malay in the west, the brown Polynesian or Sawaiori in the east No doubt there are mixtures in New Guinea or the central region also, and notably on the south-east coast, to which the brown Polynesians seem to have penetrated in more recent times But on the whole the bulk of the New Guinea people, including the adjacent Aru, Waigiu, Salwatty, Mysol, and Ké islanders, may be taken as the most typical branch of the race The western division, composed of Malayo-Papûans, and often vaguely spoken of as "Alfuros," but whom I name Sub-Papûans West, comprises the Malaysian islands of Floris, Jilolo, Ceram, Buro, Goram, Timor, Wetter, Timor Laut, and neighbouring islets, without prejudice to the question of Papûan blood in Borneo and Celêbes. The eastern division, composed mainly of Sawaiori-Papûans, and whom I name Sub-Papûans East, comprises all the South Pacific Islands grouped as Melanesia. This term, Melanesia, referring to the prevailing black colour of the natives, is in every way convenient, so that Sub-Papûan East and Melanesian may be taken as practically synonymous. Here the chief groups are the Admiralty, New Britain, New Ireland, Solomon, New Hebrides, New Caledonia, Fiji, and it is to be noted that there are some, possibly many, Melanesians who betray no trace of mixture with the brown Polynesians, and who must consequently be regarded as pure Papûans. Such are the Vanicoro and Mallicolo people in the New Hebrides, and especially the Kai Colos of Viti Levu in Fiji, some specimens of whose crania Prof. Flower has recently shown to be absolutely the most dolichocephalous on the globe. As brachycephaly is a distinctive mark of the Negrito, so dolichocephaly is of the Papûan type Consequently on this easternmost verge of the Papûan area we would seem to have, as far as is known, the very purest specimen of the race This harmonises with the view I have ventured elsewhere to express, that the type was developed in a now submerged South Pacific Continent, moving westwards with the gradual subsidence of the land For a long way east of New Guinea and North-East Australia, in fact quite as far as Samoa, the water is very shallow, averaging probably not more than 500 fathoms.

The accompanying illustrations may be taken as typical specimens of the three great divisions of the Papûan family Characteristic full-blood Papûan types are those of two members of the Wosaoni tribe, North-West Coast of New Guinea (Figs 4 and 5), from portraits by M. Raffray, originally figured in the *Tour du Monde*, for April, 1879 p 267 In Figs 6 and 7 we have good specimens of the so-called "Alfuros," or mixed Malayo-Papûans of the Archipelago, from sketches by M. Rosenberg, reproduced in his "Malay Archipelago," vol. ii. p 401. The Vanikoro chief (Fig 8), from Stanford's "Australasia," p. 476, represents a pure Melanesian head, extremely narrow and high, with long straight, but somewhat broad (platyrhine) nose and frizzly hair. In this front view the prognathism and dolichocephaly are of course not so perceptible as they would be in profile The Motu youth (Fig 9), from Stone's work, "A Few Months in New Guinea" (Sampson Low and Co), illustrates the sub-Papûan East type, the moppy head being thoroughly Papûan, while the broad face, implying brachycephaly, must be referred to Sawaiori influences. The Motu people occupy a strip of about sixty miles on the south-east coast of New Guinea about Port Moresby, and speak a language of the Sawaiori type, apparently more allied to Samoan than to Malay. O C. Stone's statement that they reckon up to one million must be received with caution, for the Samoans themselves cannot get beyond 10,000, while the Malays draw the line at 100,000 The familiar Maori (New Zealand) head (Fig 10), from Stanford's "Australasia," p 565, seems to support the now generally accepted view that the Maoris are not pure brown Polynesians, but a mixture of Rarotongans (Sawaiori stock) and Melanesians, the former predominating According to some of their traditions on their arrival, probably some 600 years ago, they found the islands occupied by an aboriginal people, who must have been Melanesians, and who were partly exterminated and partly absorbed.

In point of culture the Papûans take a far higher place not only than the Negritoes and Australians, but even than most of the African Negroes. They build houses preferably on piles, cultivate the land with great care and intelligence, are everywhere settled in fixed tribal communities governed by well-understood usages. Alfred R. Wallace, a careful observer of this race, ranks them intellectually higher even than the Malays, accounting for their social inferiority by their less favourable surroundings and remoteness from the civilising influences of more highly-cultured peoples. A very pleasing account is given by Cook of his visit to the New Caledonians, who are generally regarded as an unfavourable branch of the

family. He describes the land about the villages as "finely cultivated, being laid out in sugar-canes, plantations, yams, and other roots, and watered by little rills conducted by art from the main stream, whose source was in the hills. . . Some roots were baking on a fire in an earthern jar which would have held six or eight gallons, nor did we doubt its being their own manufacture." And further on "The plantations were laid out out with great judgment, and cultivated with much labour." The reference to earthenware is curious, because the Polynesians are generally supposed to be ignorant of the potter's art. But a taste for art in general, and especially for decoration, is one of the most distinguishing features of the Papûans Their arms, idols, houses, boats, and other objects are often adorned with very tasteful and elaborate designs, and some of their tatooing presents extremely elegant patterns They have domesticated the pig, dog, and poultry, and they cultivate the yam, sweet potato, banana, sugar-cane, taro, bread-fruit, and mango Amongst their arms, besides the spear and bow, are the bamboo blowpipe, and flint knives and axes like those of the neolithic age in Europe. Cannibalism seems to be extremely rare in the West and in New Guinea, but until suppressed was universal in New Zealand and Fiji, and is still prevalent in New Britain and many other parts of Melanesia From this division of the family it seems to have passed to the brown Polynesians, many of whom were formerly addicted to the practice It reached its climax in Fiji when, shortly before the annexation of these islands to Great Britain, a whole tribe was condemned to be roasted alive and eaten. As they were too numerous to be consumed at one meal, it was arranged that at the annual taro harvest one family should be baked and eaten with that esculent, and the arrangement was scrupulously carried out until the annexation seasonably intervened to save a remnant of the tribe (*De Rici*)

A H KEANE

(*To be continued*)

PROF. HUXLEY ON EVOLUTION

AT the meeting of the Zoological Society on December 14, among the papers read was one by Prof Huxley on the application of the laws of evolution to the arrangement of the vertebrata, and more particularly of the mammalia.

We take the following report of the paper from the *Times* —

Prof Huxley began by saying.—There is evidence, the value of which has not been disputed, and which, in my judgment, amounts to proof, that, between the commencement of the Tertiary epoch and the present time, the group of the Equidæ has been represented by a series of forms, of which the oldest is that which departs least from the general type of structure of the higher mammalia, while the latest is that which most widely differs from that type In fact, the earliest known equine animal possesses four complete sub-equal digits on the fore-foot, three on the hind-foot, the ulna is complete and distinct from the radius, the fibula is complete and distinct from the tibia; there are forty-four teeth, the full number of canines being present, and the cheek-teeth having short crowns with simple patterns and early-formed roots The latest, on the other hand, has only one complete digit on each foot, the rest being represented by rudiments; the ulna is reduced and partially ankylosed with the radius, the fibula is still more reduced and partially ankylosed with the tibia, the canine teeth are partially or completely suppressed in the females; the first cheek-teeth usually remain undeveloped, and when they appear are very small, the other cheek-teeth have long crowns, with highly complicated patterns and late-formed roots. The Equidæ of intermediate ages exhibit intermediate characters. With respect to the interpretation of these facts, two hypotheses, and only two, appear to be imaginable. The one assumes that these successive forms of equine animals have come into existence independently of one another The other assumes that they are the result of the gradual modification undergone by the successive members of a continuous line of ancestry. As I am not aware that any zoologist maintains the first hypothesis, I do not feel called upon to discuss it. The adoption of the second, however, is equivalent to the acceptance of the doctrine of evolution so far as horses are concerned, and, in the absence of evidence to the contrary, I shall suppose that it is accepted.

Since the commencement of the Eocene epoch, the animals which constitute the family of the Equidæ have undergone processes of modification of three kinds. (1) there has been an excess of development of one part of the oldest form over another; (2) certain parts have undergone complete or partial suppression, (3) parts originally distinct have coalesced. Employing the term "law" simply in the sense of a general statement of facts ascertained by observation, I shall speak of these three processes by which the Eohippus form has passed into Equus as the expression of a three-fold law of evolution. It is of profound interest to remark that this law, or generalised statement of the nature of the ancestral evolution of the horse, is precisely the same as that which formulates the process of individual development in animals generally, from the period at which the broad characters of the group to which an animal belongs are discernible onwards. After a mammalian embryo, for example, has taken on its general mammalian characters, its further progress towards its special form is effected by the excessive growth of one part in relation to another, by the arrest or suppression of parts already formed, and by the coalescence of parts primarily distinct This coincidence of the laws of ancestral and individual development, creates a strong confidence in the general validity of the former, and a belief that we may safely employ it in reasoning deductively from the known to the unknown. The astronomer who has determined three places of a new planet calculates its place at any epoch, however remote, and, if the law of evolution is to be depended upon, the zoologist who knows a certain length of the course of that evolution in any given case, may with equal justice reason backwards to the earlier, but unknown stages. Applying this method to the case of the horse, I do not see that there is any reason to doubt that the Eocene Equidæ were preceded by Mesozoic forms, which differed from Eohippus in the same way as Eohippus differs from Equus. And thus we are ultimately led to conceive of a first form of the equine series, which, if the law is of general validity, must need have been provided with five sub-equal digits on each plantigrade foot, with complete, sub-equal antebrachial and crural bones, with clavicles, and with, at fewest, forty-four teeth, the cheek-teeth having short crowns and simple-ridged or tuberculated patterns. Moreover, since Marsh's investigations have shown that the older forms of any given mammalian group have less-developed cerebral hemispheres than the later, there is a *primâ facie* probability that this primordial hippoid had a low form of brain. Further, since the existing horse has a diffuse allantoic placentation, the primary form could not have presented a higher, and may have possessed a lower, condition of the various modes by which the fœtus derives nourishment from the parent Such an animal as this, however, would find no place in any of our systems of classification of the mammalia. It would come nearest to the Lemuroidea and the Insectivora, though the non-prehensile pes would separate it from the former, and the placentation from the latter group

A natural classification is one which associates together all those forms which are closely allied, and separates them from the rest. But, whether in the ordinary sense of the word "alliance," or in its purely morphological sense, it is impossible to imagine a group of animals more closely

allied than our primordial hippoids are with their descendants Yet, according to existing arrangements, the ancestors would have to be placed in one order of the class of mammalia and their descendants in another It may be suggested that it might be as well to wait until the primordial hippoid is discovered before discussing the difficulties which will be created by its appearance. But the truth is that that problem is already pressing in another shape Numerous "lemurs," with marked ungulate characters, are being discovered in the older Tertiaries of the United States and elsewhere, and no one can study the more ancient mammals with which we are already acquainted without being constantly struck with the insectivorous characters which they present In fact, there is nothing in the definition of either Primates, Carnivores, or Ungulates, which affords any means of deciding whether a given fossil skeleton, with skull, teeth, and limbs almost complete, ought to be ranged with the Lemurs, the Insectivores, the Carnivores, or the Ungulates.

In whatever order of mammals a sufficiently long series of forms has come to light they illustrate the three-fold law of evolution as clearly, though perhaps not so strikingly, as the equine series does Carnivores, Artiodactyles, and Persso-sodactyles all tend, as we trace them back through the Tertiary epoch, towards less modified forms which will fit into none of the recognised orders, but come closer to the Insectivora than to any other It would, however, be most inconvenient and misleading to term these primordial forms Insectivora, the mammals so-called being themselves more or less specialised modifications of the same common type, and only, in a partial and limited sense, representatives of that type The root of the matter appears to me to be that the palæontological facts which have come to light in the course of the last ten or fifteen years have completely broken down existing taxonomical conceptions, and that the attempts to construct fresh classifications upon the old model are necessarily futile The Cuvieran method, which all modern classifiers have followed, has been of immense value in leading to the close investigation and the clear statement of the anatomical characters of animals But its principle, the association into sharp logical categories defined by such characters, was sapped when Von Baer showed that, in estimating the likenesses and unlikenesses of animals, development must be fully taken into account, and if the importance of individual development is admitted, that of ancestral development necessarily follows. If the end of all zoological classification is a clear and concise expression of the morphological resemblances and differences of animals, then all such resemblances must have a taxonomic value But they fall under three heads (1) those of adult individuals; (2) those of successive stages of embryological development or individual evolution, (3) those of successive stages of the evolution of the species, or ancestral evolution. An arrangement is "natural," that is, logically justifiable, exactly in so far as it expresses the relations of likenesses and unlikenesses enumerated under these heads Hence, in attempting to classify the Mammalia, we must take into account not only their adult and embryogenetic characters, but their morphological relations, in so far as the several forms represent different stages of evolution And thus, just as the persistent antagonism of Cuvier and his school to the essence of Lamark's teachings (imperfect and objectionable as these often were in their accidents) turns out to have been a reactionary mistake, so Cuvier's no less definite repudiation of the principle of Bonnet's "*échelle des êtres*" was no less unfortunate. The existence of a "scala animantium," is a necessary consequence of the doctrine of evolution, and its establishment constitutes, I believe, the foundation of scientific taxonomy. Many years ago, in my lectures at the Royal College of Surgeons, I particularly insisted on the central position of the Insectivora among the higher Mammalia; and further study of this order and of the Rodentia has only strengthened my conviction that any one who is acquainted with the range of variation of structure in these groups possesses the key to every peculiarity which is met with in the Primates, the Carnivora, and the Ungulata Given the common plan of the Insectivora and of the Rodentia, and granting that the modifications of the structure of the limbs, of the brain, and of the alimentary and reproductive viscera which occur among them may exist and accumulate elsewhere, and the derivation of all Eutheria from animals which, except for their diffuse placentation, would be Insectivores, is a simple deduction from the law of evolution. I venture to express a confident expectation that investigation into the mammalian fauna of the Mesozoic epoch will, sooner or later, fill up the blanks which at present exist in the "scala mammalium" Prof. Huxley proceeded to give details on which his conclusions were based, and dwelt on the fact that much further careful work is needed to clear up problems before us

NOTES

We are enabled through the courtesy of the Council of the Royal Society of Edinburgh to present our readers with an abstract of a remarkable paper by Mr John Aitken, on Dust, Fog and Mist The paper opens up new lines of inquiry, and indeed a new future, to what has hitherto been one of the most difficult branches of meteorology, viz the investigation of the vapour of the atmosphere, which we may safely predict meteorologists will not be slow in following up Mr. Aitken continues the prosecution of the inquiry, and we learn that last week he has experimented with temperatures as low as 14°·0 F. with the result that equally as at higher temperatures, there is no cloudy condensation when there is no dust, but, when there is dust, cloudy condensation takes place on the dust nuclei, the amount of cloudiness being of course relatively small at such low temperatures on account of the small amount of vapour present. Taken along with Prof. Lister's experiments, in which it was shown that a single drop of rain developed organisms in sensitive solutions which would otherwise have remained for months unaltered, it shows that germ-producing matter, or germs themselves, form at least a part of the cloud- and fog-producing dust. Hence a cotton-wool respirator may prove a protection against disease We have said enough to show that the paper is one of interest, not only to the physicist and the meteorologist, but also (and perhaps even specially) to the physiologist and the sanitarian.

We are pleased to learn that Dr. W. De La Rue, F R S, has been chosen a Corresponding Member of the Paris Academy of Sciences in the Section of Astronomy

Baron de Chaudoir, Mr. McLachlan, and Baron C. R. Osten-Sacken have been elected honorary members of the Entomological Society of Belgium, filling the vacancies in the list caused by the deaths of Dr. Boisduval, M. Mulsant, and Dr. Snellen van Vollenhoven.

It is proposed to hold a meeting of the Association for the Improvement of Geometrical Teaching on Friday, January 7, in the Botanical Theatre of University College, Gower Street, at 11 a.m. The sub-committees appointed January 11, 1878, have prepared, and circulated amongst the members, draft syllabuses of solid geometry, higher plane geometry, and geometrical conics, and will present their Reports at the meeting. All persons interested in the elementary teaching of geometry are invited to attend.

According to a resolution of the St. Petersburg Society of Naturalists, the work of Prof. Wagner on "Medusæ and

Hydroids of the White Sea," will be published in German and French, with fifty tables of engravings.

THE Peabody Academy of Science (Salem, Massachusetts, U.S.A.), after a forced suspension of its publications for six years, announces that the *Memoirs* will be resumed at an early date.

DR. HOEK of Leiden writes us that a first part of the Zoological Results of the Dutch Arctic Cruises with the 60-ton Schooner *Willem Barents* will shortly be published. These results—a preliminary report of which Mr. D'Urban has given in the October number of the *Ann. and Mag. of Nat. Hist.*—will be published as an extra volume of the *Niederlandisches Archiv fur Zoologie* (Leiden, E. T. Brill). The different articles will be written in English, French, or German, and the distribution of the material has been as follows:—Sponges, Dr. G. C. J. Vosmaer; Echinoderms, Prof. C. K. Hoffmann; Hydroids and Polyzoa, Dr. W. J. Vigelius; Nemertineans, Dr. A. A. W. Hubrecht; other Worms, Dr. R. Horst; Pycnogonids and Crustaceans, Dr. P. P. C. Hoek; Lamellibranchiate Mollusks, Mr. D. van Haren Noman; Gastropodous Mollusks, Mr. Th. W. van Lidth de Jeude; Fishes, Dr. A. A. W. Hubrecht; Birds, Prof. H. Schlegel. The first part contains the Worms, the Pycnogonids, the Lamellibranchiate Mollusks, the Fishes, and a description of the only mammal captured, and will be issued before the end of January.

THE death is announced of Prof. Karl B. Heller of the K. K. Theresianum at Vienna, a naturalist well known by his numerous writings.

REPORTS from Honolulu describe an eruption of the Mauna Loa Volcano (Hawai) as the grandest which has ever been observed. It began on November 5 at some nine kilometres distance from the summit of the crater. The eruption of lava was accompanied by terrible explosions.

EARTHQUAKES are reported (1) from Brescia, where a shock was observed on December 10 in the afternoon; (2) from Schloss Trakostyan and environs (in the mountains of Northern Croatia), where three violent shocks occurred in the night of December 10-11; (3) from Smyrna, where, on December 12 at 9.40 p.m., a tolerably powerful shock was noticed. On the 23rd inst., about 5 p.m., a shock of earthquake was felt at Bucharest, Rustchuk, Kustendje, Galatz, Berlad, and Jassy. In the night of December 16-17 two earthquake shocks were felt in Agram, in close succession, about 11 p.m. About the same hour shocks were observed in various parts of Carniola and Styria, *e.g.* in Gurkfeld at 11.4 and 11.9 p.m., in Grossontag, near Friedau, three quickly-successive shocks; in Pragerhof two pretty sharp shocks; in Peltau and in Marburg one strong shock each. In Csakathurn (Hungary) and neighbourhood strong earthquake motions were likewise observed the same night about 11.20 p.m. In the night of December 21-22 shocks were again felt in Agram, of which one about 1 a.m. was pretty violent. In the environs of Agram slight earth-vibrations are still constantly being experienced. At about ten minutes past five o'clock p.m. on December 25 two rather severe shocks of earthquake occurred at Odessa within a very short interval of each other. They appear to have come from the direction of the Middle Danube, and, passing through Roumania and Bessarabia, spent themselves here on the shores of the Black Sea in South Russia. They seem to have been most strongly felt at the Bessarabian towns of Bieletz, Kishineff, and Tiraspol, for the walls of some of the houses were cracked in consequence. At Odessa the effects were limited to buildings and furniture being more or less roughly shaken, or light articles such as vases, bottles, and glasses, being thrown down. The weather was extremely mild and calm at the time, and the sky but very partially clouded.

FALB's theory is gaining in favour with the population, especially as he predicted fresh earthquakes in the Agram region from December 15 to 31. Falb has enunciated his theory in a newly-published popular work entitled "Die Umwälzungen im Weltall" (Revolutions in the Universe). These are treated under three heads: (1) in the star regions, (2) in the region of clouds, and (3) in the depths of the earth.

THE tomb of Immanuel Kant at Konigsberg will soon be decorated in a worthy manner. Upon a suitable pedestal a marble bust of the great philosopher will be placed. The bust is the work of Prof. Siemering.

"ALLERLEI gesammelte ornithologische Beobachtungen" is the title of a new book from the pen of Rudolf, Crown Prince of Austria, just published in a limited number of copies, which have been presented by the author to his friends.

A MONUMENT of the celebrated ornithologist Naumann was recently unveiled in the Schlossgarten at Kothen upon the occasion of the centenary of Naumann's birth.

THE German Fisheries Union have, according to the proposal of Prof. Nitsche of Tharand, resolved to offer a prize of 500 marks (25*l.*) for the best treatise on the following subject:—Of the ova of fish which are sown out for breeding, and particularly of the ova of the Salmonidæ, a large percentage is completely destroyed by fungi, well-known to pisciculturists as byssus or "mould," and belonging partly to the family of Schizomycetæ and partly to that of Saprolegniaceæ. A detailed botanical description of the respective genera and species, their biology and propagation, as well as an account of the manner of their introduction into the piscicultural apparatus, of the conditions which favour their development and of the way in which they destroy the ovum, is now required. At the same time the questions are to be discussed whether and by what means it would be possible to prevent their introduction, and what measures would best stop a continued spreading of the evil when once introduced into a breeding place. The treatises are to be sent, under the usual formalities, to the office of the German Fisheries Union, 9, Leipziger Platz, Berlin. The competition for the prize is to be an international one, and the treatises may be written in German, English, or French. The final term is October 1, 1882.

WE have received specimens of the diaries published by Messrs. De La Rue. While their beauty and convenience commend them to everybody, they ought to be of special value to lovers of science, as they contain so many scientific data. Their get-up and general utility are beyond praise.

THE *Comptes rendus* of the Paris Academy of Sciences for December 20 is entirely occupied with the discourses pronounced at the funeral of M. Michel Chasles by representatives of the various bodies with which the deceased member was connected—MM. J. Bertrand, Bouquet, Laussedat, Dumas, and Rolland.

AT the last meeting of the St. Petersburg Society of Gardening M. Grigorieff made an interesting communication on Japanese gardens. The Japanese are most passionate lovers of gardening, which is carried on by all classes of society, from the great palaces to the most humble houses. Gardening, as well as the art of making bouquets, is taught in schools, and nowhere else in Europe are there so many gardens as in Japan. The species cultivated in the small private gardens are mostly miniature representatives of great trees. All new species and varieties of garden flowers and trees are sold at high prices and become known throughout the country with great rapidity. M. Grigorieff exhibited during his lecture a most interesting collection of photographs of Japanese gardens.

THE Russian scientific bodies continue to express their sympathy with Prof. Mendeleeff on the occasion of the refusal

by the Academy of Sciences to admit him as Member of that body. The Russian Chemical and Physical Society, while electing him Honorary Member, has presented him with an address in which it is stated that the Society considers him "to be a chemist who has no equal among Russian chemists" Many scientific bodies, as the University of Kieff, the Society of Hygiene, &c, have elected him Honorary Member or President. A public subscription has been opened for the institution of a prize bearing his name, and a great dinner was given in his honour by the St Petersburg *savants*, among whom we notice the most eminent Russian Members of the Academy of Sciences It is worthy of notice that Professors Korkin and Setchenoff, as well as the late M. Hilferding, the Panslavist explorer of Slavonian literature, met at the hands of the Academy of Sciences the same fate as M. Mendeleeff.

THE law for the isolation of the French National Library has been adopted by both Houses of the French Parliament, and the necessary expropriation for the great work will begin immediately

AT a recent sitting the Municipal Council of Paris voted a sum of 400*l*. for the establishment of a School of Chemistry. It will be opened free to the pupils of the several Municipal schools who are desirous of practice in chemical industrie.

THE French Government is to establish in Egypt a school of Egyptology, which will be directed by M Maspero, now Professor of Egyptology to the College of France This creation will be the third school established abroad at the expense of the French Budget. The two others are one at Rome and the other at Athens.

THE Thirteenth Annual Report of the Eastbourne Natural History Society testifies to the Society's continued prosperity At the meeting of November 19 Dr Royston Pigott read an interesting paper on "The Limits of Human Vision"

THE *Proceedings* of the Belfast Natural History and Philosophical Society for 1878-80 contains, besides several general papers, a few natural history papers of local interest, including one (with illustrations) on Irish Spiders, by Mr Thomas Workman.

A BALNEOLOGICAL and a patent protection exhibition will be held at Frankfort-on the Main in 1881.

OUR ASTRONOMICAL COLUMN

VARIABLE STARS—Amongst the stars which, from a comparison of the various catalogues, exhibit more or less strongly signs of variability, may be mentioned the following, which we take in order of right ascension, the positions are for the year 1880:—

1 Lalande 2037-8. R.A. 1h. 3m. 24s, N P.D. 38° 30′ 5. On September 29, 1790, Lalande rated this star 10m., and on December 27 following, 8·9; the B.D. (by which letters we refer to the Bonn *Durchmusterung*) has 7 0. Harding marks it a ninth.

2 40 Cassiopeæ. R A. 1h 28m 57s, N.P n Lalande calls this star 4m. in September, 1789, and 6 i 1790. In Argelander's zone No. 167 on January 1, 1843, i was estimated 7, yet in the B.D. it is 5 2 In the first Radcliffe catalogue, where great attention was given to the magnitudes, it is 4 7, Piazzi has 6, Groombridge 5 6, and Heis the same.

3 Lalande 4864 5. R.A. 2h 32m. 15s., N.P D 40° 57′·4 Estimated 9 in September, 1790, and 7½ in January following; but it has since been discerned with the naked eye, Heis calling it 6 7. The B.D. has 6·7 It is not in Houzeau

4 Bradley 396. R.A 2h. 53m. 13s., N P.D. 8° 59′ 8. Lalande rated this star 4 5 in November, 1789, and 7 in March, 1790. Groombridge, who made six observations for position, estimated it 7, Heis and Carrington 6, while it is 5·5 in the B.D

5. 35 Camelopardi. We have already referred to the marked discordances in the estimates of the magnitude of this star in the various catalogues Dembowski has directed attention to the probable variability of the principal component, and the star certainly deserves more regular attention at the hands of observers than it has yet received. R.A. 5h. 54m 58s., N P D. 38° 25″5 The estimated magnitudes vary from 5 5 to 8.

6. Attention may be once more directed to the star which Rumker compared with Encke's comet at Paramatta, N S W., on June 19, 1822, and which he rated at the time 4 5 Whether it really attains this degree of brightness is not yet certain, it is however 6·0 in the *Uranometria Argentina*, and was observed as low as 8m. in 1873. The B D says 6 5. Its light is a full yellow R.A 7h 23m 15s, N.P D 91° 39′ 5.

7 65 b^3 Geminorum. R A 7h 22m 21s, N.P.D 61° 50′ 3. Lalande rated this star as low as 8¼ in March, 1794, but calls it 5½ in February following Bessel estimated it 7, all other observers say 5 or 5 6.

8 16 Leonis Minoris R A. 9h 42m 51s., N P D. 49° 48′ 7. D'Agelet has 5 and 7 8, Lalande 6½, Piazzi 8, the first Radcliffe Catalogue 6 6, Bessel, Taylor, and the B D 7, Houzeau 5 6, but neither Argelander nor Heis included it amongst the stars visible to the naked eye

9 Lalande 19034. R.A 9h. 34m. 49s, N.P D. 113° 2′ 7. It appears strange that a star isolated as this is should not have been more frequently observed on the meridian, if always as bright as say 5m. D'Agelet and Piazzi have not got it, Lalande calls it 4½ on March 21, 1797, Argelander has 6 on March 6, 1850, 4 on February 16, 1851, and 5 on March 8, 1852, Heis and Houzeau call it 5, and Gould 5 2.

If we may rely upon the observations of Kirch early in the last century there would appear to be sensible changes in the relative brightness of β and δ Scorpii, on January 17, 1704, he writes "β und δ erschienen fast im gleicher Grosse, jedoch δ ein wenig heller (jetzt ist β 2, δ 3 grosse)," while on April 1 following he records "δ merklich grosser als β" Argelander and Heis estimate β and δ respectively 2 and 2 3, Gould has no sensible difference.

10 Lalande 38405. R.A 20h, 0m. 16s, N.P D. 94° 45′ 4. This star was rated 6 on July 15, 1794, 7 on August 15, 8 on August 20, and 7½ on August 30 of the following year It is 8 in Bessel, 7 in Wolfer's map, one of the series of the Berlin Academy, and 6·7 in Heis and Houzeau Gould does not give it It might be inferred from Lalande's observations that the period is not very long

11 33 Capricorni. Chacornac says of this star. "Observée tantot plus brillante, tantot moins qu'une étoile de 7me grandeur dont elle est voisine" the seventh magnitude alluded to being, it may be presumed, O A 21386, which follows 2m. 12s., 9′·4 to the south 33 Capricorni is 5 6 in Argelander, 6·5 in Heis and Behrmann, and 5·7 in Gould, it is one of Chacornac's red stars, Gould also calls it red The evidence of variability in this case seems to rest with Chacornac R A 21h 17m 21s., N P D. 111° 21″5.

12. 17 ι Andromedæ, a star previously noted in this column as variable In the "British Catalogue" it is rated 4, Bradley and Piazzi call it 7; Lalande's three estimates are 5, 5 and 4, D'Agelet has 3 4 and 6, the first Radcliffe catalogue 3 9, and the B.D. 4 2; estimates from 4 to 7 are therefore sufficiently confirmed, the variation may be slow, but the star certainly deserves attention R A 23h 32m. 15s, N P D 47° 24′ 1.

THE COMET 1873 VII—The comet discovered by Coggia at Marseilles on November 10 and by Winnecke on November 11 was soon lost in Europe from its rapid southerly motion; indeed the observations extend over less than a week. The elements exhibited a similarity to those which had been assigned to a comet detected by Pons in February, 1818, but very imperfectly observed, and Prof. Weiss, the present director of the Imperial Observatory at Vienna, was at the trouble of examining the question of possible identity as closely as the data permitted. He formed three normal positions from the small number of observations—for November 11, 13, and 15—and under the condition that the first and third normals should be exactly represented he ascertained how the second one was represented on the assumption (1) that the orbit was parabolic, (2) that the period of revolution corresponded to the interval between the perihelion-passages in 1818 and 1873, or 55 82 years, and (3) that the comet had completed eight revolutions in this interval, or that the period extends only to 6 977 years. As a matter of figures the agreement was found to be slightly closer for hypothesis (3) than for the other two, the parabola showing the largest differ-

ence. Hence so far as the paucity of data in 1873 enabled any judgment to be formed, the preference appeared to belong to the revolution in 6·977 years. On this supposition there would be a very near approach to the orbit of Jupiter near the ascending node, which would render possible an amount of perturbation at some past time, that might have fixed the comet in an orbit of such limited dimensions.

If the comet were really revolving in an elliptical orbit with this period of revolution, neglecting perturbations, which might however be sensible since 1873, it would be again due at perihelion about November 24 in the present year, in which case its track in the heavens would not be very different from that followed in 1873. We are not aware if any search has been made for the comet. It would have been possible to have decided in 1873 if a short period were admissible could observations have been obtained in the southern hemisphere: this was not done, and the identity of the comets of 1818 and 1873 remains therefore open to conjecture; but it must be borne in mind that the data in the former year are in a high degree uncertain.

PECHULE'S COMET.—Elements computed by the discoverer from observations at Copenhagen on December 16, 17, and 20, have a general resemblance to those of the comet of 1807, so elaborately discussed by Bessel, but after his resulting period of many centuries, and considering the position of the orbit in the system, there can be of course no question of identity of these bodies. At Greenwich noon on January 1 the comet's position will be, by Pechule's elements, in R.A. 20h. 1·9m., N.P.D. 70° 24′, and on January 5 in R.A. 20h. 19·6m., N.P.D. 68° 30′.

CHEMICAL NOTES

MM. HAUTEFEUILLE AND CHAPPUIS, in continuing their investigation of the conditions under which oxygen is transformed into ozone, have shown in *Compt. rend.* that the character of the electric discharge to which the oxygen is subjected largely influences the quantity of ozone produced. If the discharge assume the character of a luminous shower the maximum amount of ozone is produced, the temperature of such a discharge being lower than that of the ordinary *effluve*. The production of this special form of discharge is ensured by mixing with the oxygen a small quantity of a foreign gas whose physical properties are dissimilar from those of oxygen; of the gases experimented with silicon fluoride has given the best results. If nitrogen be the foreign gas the transformation into ozone is greater than when pure oxygen is employed, but the discharge is not altogether luminous. Hydrogen is more effective than nitrogen. The presence of carbon dioxide also insures a large amount of ozonation. In their earlier experiments on the liquefaction of ozone the authors only succeeded in obtaining a mist in the Cailletet tube when the pressure was suddenly withdrawn. They now find that if a mixture of carbon dioxide and oxygen which has been ozonised at a low temperature be submitted to the action of the silent discharge at − 23°, and be slightly compressed, the gas acquires a deep blue colour, and after a time a blue liquid is produced. At − 88° the liquid is very dark blue. When carbon dioxide is decomposed by the electric spark at − 23° a blue gas is produced, and at a certain pressure (exact pressure is not mentioned) the undecomposed carbon dioxide condenses to a blue coloured liquid. By this experiment the authors think they have proved that ozone is one of the products of the decomposition, by the spark, of carbon dioxide.

THE heat of formation of benzene has recently been measured by Thomsen (*Berliner Berichte*) and by Berthelot (*Compt. rend.*). The results show considerable differences, but from the accounts of the experiments, Thomsen's number seems the more trustworthy. For the heat of combustion of gaseous benzene Thomsen finds the number 805,800 heat units; Berthelot the number 776,000. For the heat of formation of gaseous benzene, at constant volume, from amorphous carbon and hydrogen, Thomsen finds − 20,120 heat units; Berthelot, on the other hand, finds + 5800. Berthelot does not state whether this number is calculated for constant volume or constant pressure. Thomsen makes certain theoretical deductions from the value which he has found for the heat of formation of benzene, basing these on his calculations for the heat of formation of "singly- and doubly-linked" carbon atoms (see NATURE, vol. xxii. p. 608): he concludes that the generally accepted hexagon formula for benzene is probably incorrect, and that a formula in which each carbon atom is "singly linked" to three others is to be preferred.

BERTHELOT finds the heat of formation of gaseous dipropargyl—C_6H_6—a metamer of benzene—from amorphous carbon to be − 64,800 heat units. The instability and easy polymerisation of this body are explained by the great absorption of heat which occurs in its formation. Attempts to transform dipropargyl into benzene were unsuccessful. Berthelot has also determined the heats of formation of various hydrocarbons, and finds certain constant differences between the successive members of homologous series.

HERR V. MEYER describes in the *Berliner Berichte* a very elegant modification of his method of determining vapour densities, whereby the specific gravities of permanent gases may be readily measured at very high temperatures. At the highest temperature of a Schlösing's furnace (about 1400°) the density of hydrogen vapour was normal. It has now been shown that the coefficients of expansion of the following gases are not changed at very high temperatures: tellurium, sulphur, nitrogen, oxygen, hydrogen, mercury, carbon dioxide, hydrochloric acid, arsenious oxide.

THE following numbers for the vapour densities of tellurium and selenium have been recently obtained by Deville and Troost (*Compt. rend.*):—Selenium at 1420° = 5·68 (calculated = 5·54), tellurium at 1440° = 9·0, at 1390° = 9·08 (calculated = 8·93).

IN the *Wien Acad. Berichte* Herr Offer describes the results of experiments which he thinks show that Guthrie's cryohydrates are merely mixtures of various salts and ice: alcohol dissolves the ice, leaving a "skeleton" of undissolved salt; cold water dissolves the salt, and leaves the ice with the form of the cryohydrate. Solution of a cryohydrate is attended with the same thermal change as solution of the salt and ice separately.

THE connection which exists between the opium and cinchona alkaloids, and between both of these groups of compounds and pyridine, has been recently made more apparent by the work of Herr E. v. Gerichten (*Berliner Berichte*), who has shown that the so-called apophyllenic acid—obtained by oxidising the opium alkaloid cotarnine—is really the acid methyl salt of pyridine dicarboxylic acid, which acid is obtained from the cinchona alkaloid cinchonine, and which when heated with lime yields pyridine.

WHEN an aqueous solution of potassium, sodium, or lithium chloride, or potassium nitrate is kept for some time in a vertical tube, the upper part of which is maintained at a considerably higher temperature than the lower part, diffusion of the salt from the hotter to the colder part occurs, according to M. C. Soret (*Naturforscher*). The amount of diffusion in a given time depends upon the original concentration of the solution, and is also connected with the molecular weight of the salt used.

M. DUFET stated some little time since that the refractive index of a mixture of isomorphous salts in solution is equal to the mean of the indices of the components. Herr Fock (in *Zeitschrift für Crystallographie*) concludes, from measurements of the refractive indices of solutions of thallium and potassium alums, of lead and strontium thiosulphate, and of magnesium chromate and sulphate, that Dufet's statement does not hold good in all cases: for the second pair of salts mentioned above it is approximately correct. In *Compt. rend.* Dufet gives numbers showing that his statement applies to a mixture of magnesium and zinc sulphates.

In *Compt. rend.* M. Demarçay describes two new compounds containing sulphur, nitrogen, and chlorine, viz., SNCl and $(SN)_3Cl$: the former prepared by passing chlorine into a solution of nitrogen sulphide in chloroform, and the latter by adding nitrogen sulphide to a solution, in chloroform, of the compound SNCl. SNCl is partly decomposed by heat, in accordance with the equation $2SNCl = N_2 + S_2Cl_2$.

THE relation between the total energy developed in the chemical reactions which occur in various kinds of galvanic batteries and the energy which appears in the form of current electricity, has been recently studied by Thomsen (*Wiedemann's Annalen*) using a thermal method of measuring the total energy. He finds that the whole of the energy developed in the chemical change appears as electric energy in Daniell's battery (with closed circuit), and in those forms of batteries in which the metallic surface of the negative electrode is not changed by the electrolytic process; when nitric acid is used as electrolyte the same total conversion of one into another form of energy is

nearly realised, but the gradual absorption, by the liquid, of reduction products, tends to cause a deviation from this result.

BERTHELOT has recently studied (*Compt rend*) the action of air and of hydrochloric acid in presence of air, on pure mercury. He confirms the generally accepted fact that pure mercury is very slowly and superficially oxidised by the action of air at ordinary temperatures. If gaseous hydrochloric acid is shaken with mercury in presence of air mercurous chloride and water are produced. This reaction ($Hg_2 + 2HCl + O = Hg_2Cl_2 + H_2O$) is attended with the evolution of 53,400 thermal units, whereas the oxidation of mercury ($Hg + O = HgO$) is attended with the evolution of only 21,100 units. The action of hydrochloric acid in presence of air on copper ($Cu_2 + 2HCl + O = Cu_2Cl_2 + H_2O$) is accompanied by the evolution of 26,500 thermal units, hydrochloric acid in absence of air is, as is well known, almost without action on metallic copper.

IN the course of his investigation into the action of phosphorus on hydriodic acid, Damoiseau (*Compt rend*) describes a method for preparing phosphonium iodide in a state sufficiently pure for general use. Ten parts ordinary phosphorus in small pieces are allowed to react for some time on twenty-two parts of an aqueous solution of hydriodic acid (saturated in the cold), two parts iodine are added, and the phosphorous acid which is produced is separated from the crystals of phosphonium iodide by washing with aqueous hydriodic acid.

A SERIES of compounds, derived from monohydric alcohols, in which the "hydroxylic hydrogen" of the alcohol is replaced by aluminium, is described (*Chem News*) by Gladstone and Tribe. These bodies are prepared by the action of aluminium in presence of aluminium iodide on the alcohol. The new substances are solids, melting to clear liquids which do not solidify at temperatures much below the melting points of the solids, they are decomposed by water with formation of aluminium hydrate and the corresponding alcohol.

THE sulphides of vanadium have been investigated by Kay (*Chem. Soc Journ.*). The compounds obtained by Berzelius by the action of sulphuretted hydrogen on solutions of vanadium salts are shown to contain oxygen in addition to vanadium and sulphur, but no definite formula can be assigned to any of these bodies. Vanadium trisulphide V_2S_3 is obtained by the action of dry sulphuretted hydrogen on heated vanadium trioxide, as described by Berzelius. When this compound is heated to bright redness in hydrogen, it is reduced to the disulphide V_2S_2, and when heated with sulphur to 400° it is converted into the pentasulphide V_2S_5.

IN the *Chem. Soc. Journ* Kingzett describes experiments on the atmospheric oxidation of phosphorus which seem to prove that ozone and hydrogen peroxide are simultaneously produced when air is drawn over phosphorus partially immersed in water.

MANY so called basic sulphates of iron have been from time to time described: of the fifteen which are generally recognised as probably existing it would appear from Pickering's experiments (*Chem Soc. Journ.*) that only one, viz. $2Fe_2O_3\ SO_3$, actually exists.

DR. SYDNEY MARSDEN has recently experimented on the action of boron on various metals at high temperatures. He finds (*Proc R. S. Edin* and *Chem. Soc. Journ*) that silver dissolves amorphous boron, and that on cooling, pure boron is obtained partly in the graphitoidal, partly in the adamantine form. Copper combines with boron to form the compound B_2Cu_3.

PROF. BELLATI has published in pamphlet form, under the title "Proprietà termiche notevoli di alcuni Ioduri doppi," an extended and careful series of observations of the specific gravities, specific heats, thermal expansions, and thermal changes which accompany changes of colour and structure, of several double iodides of mercury, more especially of the three salts $HgI_2 . 2AgI$, $HgI_2 . 3AgI$, and $HgI_2\ Cu_2I_2$.

HERR HAASS describes in the *Berliner Berichte* a simple method of illustrating the existence of the so-called "critical pressure" described in this journal by Carnelley. A small piece of mercuric chloride is placed in a glass tube which is closed at one end, and communicates at the other with a Bunsen pump. So long as the manometer registers less than about 400 mm. pressure it is not possible to melt the mercuric chloride by heating it; the salt passes at once from the solid to the gaseous state. But immediately the pressure rises above about 420 mm. the mercuric chloride melts.

IN studying the condensation products of aldehyde Prof. Lieben has obtained (*Wied Akad. Ber.*) a new alcohol belonging to the same series as glycerin, viz. $C_4H_7(OH)_3$. The new compound, called butenyl glycerin by Lieben, is a syrupy, sweet-tasting liquid, soluble in water, boiling at 172°–175° under a pressure of 27 mm. It forms a triacetin analogous in properties to the natural fats, when heated with oxalic acid its behaviour is similar to that of glycerin: formic acid is produced along with an oily, strongly smelling substance which has not as yet been fully examined.

PHYSICAL NOTES

MONS A ANGOT proposes a new formula for calculating altitudes from barometric observations, based upon that given originally by Laplace. The existing method of calculation from observed monthly or annual means is found, as Plantamour has shown, to be defective, since its results exhibit an uncertainty that varies with the season, an elevated station appearing to be higher by day and in summer than at night or in winter. As an example, when the height of the Great St. Bernard is measured by comparison of barometer observations between that place and Geneva, it would appear that the height of the Great St. Bernard exhibits a diurnal variation of 17 metres in winter and of more than 47 metres in summer, while the mean of the June observations gives a height of 25 metres higher than that found from the January numbers! These anomalies M Angot explains by the facts that the mean temperature between the stations is not exactly equal to the half sum of the two temperatures, and that the weight of the air between the two stations is on the other hand greater when the mean temperature is low. The rather complicated formula proposed by M Angot gives the difference in altitude by calculating directly the height of each station above an imaginary plane at which the barometric pressure is equal to 760 millims. No empirical coefficients are needed in this case, the standard constants of Regnault and others for air and aqueous vapour being taken. M. Angot has recalculated from his formula a new set of tables, involving all the corrections that must be applied to the older tables of the Bureau des Longitudes.

IN a recent number of the *Journal de Genève* M Colladon has pointed out that a poplar or other tall tree may, if its roots strike into damp soil, serve as a lightning-conductor to protect a house, and he thinks he has verified this conjecture by examination of a number of individual cases of lightning-stroke. In the case however where the house stands between the tree and a piece of water, a pond or a stream, the shortest path for the lightning from the tree to the wet conductor may be through the house!

V VON ZOCH has described a new kind of electric dust-figures, which he regards as having an important bearing upon the theory of discharges in vacua, being in opposition to the views of Crookes. Tubes of 1 to 3 centims. diameter, and from 10 to 30 centims in length, were closed at both ends by corks pierced to receive copper wires. In the tubes were placed various powders, bronze powder being chiefly used in preference to others, which being lighter adhered to the sides of the tube. One wire was then connected with the positive conductor of an electric machine; from the other the repelled electricity dissipated itself into the air. In other cases the discharges of Leyden jars were employed. The experiments were all conducted at atmospheric pressure. When thus treated the bronze powder arranged itself in beautifully-marked ridges or strata, varying in regularity according to the original distribution of the powder. A space free from all traces of powder was observed to surround the positive pole. Usually there was a corresponding accumulation about the negative pole. These ridges or striations may be compared to the stratifications observable in Geissler tubes; and Herr Zoch shows that variations in the strength of the electric discharges, in the width of the tubes, &c., produce upon these figures similar effects to those they produce on the luminous striæ of vacuous tubes. In this present case a mechanical repulsion of the particles lying near the poles undoubtedly takes place, and the author of this research believes that the presence of light at the poles of the Geissler tube may be similarly accounted for on the hypothesis that the luminous regions are those of less density than the non luminous. Since the bronze powder is heaped up mostly about the negative pole the inference is that at the negative pole of a Geissler tube the residual gas has a greater density than at

any other part The stratifications produced by electric discharges through flames may be similarly explained; and these researches have an obvious bearing on the structure of Lichtenberg's well-known figures

MONS MERCADIER has been devoting some attention to the subject of the photophone, and more particularly to the production of sounds by the simpler forms of the instrument, in which a selenium receiver with its electrical connections is dispensed with The musical photophone—or, as M Mercadier chooses to style it, the radiophone—may be described as a sort of optical siren, in which a rotating disk pierced with holes is interposed in the path of a period of rays of light, causing intermittences of regular period varying with the speed of the disk Our readers will remember that such a beam falling on a simple disk of metal or of hard rubber throws it into vibration, and it emits a note corresponding in pitch with the frequency of the intermittences of the light In Prof Bell's actual instrument this "siren" was a heavy disk of brass pierced with holes M. Mercadier prefers a disk of black paper gummed upon a glass disk in order to get rid of the whistling sounds which even a gentle current of air produces on the brass disk It may be noted in passing that M Duboscq has independently constructed similar disks The receiving disks were fixed in a suitable holder at the end of a short india rubber hearing-tube M. Mercadier finds that when opaque disks of zinc, copper, and other substances are employed to receive the beams, very little difference in the loudness of the sounds can be perceived, whether the disks are polished or not. But the thickness of the disks is of great importance, thin ones answering much better than those a little thicker With transparent laminæ such as glass and quartz, M. Mercadier obtains strong effects, whereas Prof. Bell found only feeble results with these substances The degree of polish is here unimportant also; but a film of smoke or white paint, or of metallic silver on the front of the disk, diminishes its powers, while, on the contrary, the loudness is augmented by blackening the back of the disk M Mercadier employed as sources of light the lime-light and flames of petroleum fed with oxygen.

HERR F. KLOCKE has lately discovered an anomalous property in hyposulphite of lead in respect of its action on polarised light. This substance usually exhibits circularly polarised light but Klocke has found that plates cut perpendicularly to the optic axis, when viewed in the field of a polariscope by parallel rays of light, appear unequally bright, being divided by dark bands into six sectors, of which opposite pairs are equally bright In convergent light, moreover, the ordinary ring figure of a uniaxial crystal is not seen, but instead there appears in each sector a figure of the form characteristic of the ordinary biaxial crystal, and having the plane of the optic axes perpendicular to the neighbouring edge of the crystal The explanation of this curious phenomenon appears to be that there is some anomaly in the molecular structure of the crystals, by virtue of which the six portions are compressed equally each in direction perpendicular to the neighbouring face of the prism.

IN the Vienna *Berichte* for June, 1880, Victor von Lang describes a form of dichroiscope, in which a small improvement upon the common form has been made Usually the small square aperture through which light is admitted to the rhomb of spar is fixed rigidly to the tubular holder of the latter In the new form the square aperture is cut in a diaphragm fastened to an outer tube, which can be rotated round the inner The advantages gained in permitting the rhomb of spar to be turned independently of the aperture are obvious. A plano-convex lens of small magnifying power is added as usual as an eyepiece at the other end of the rhomb.

M. AMAGAT has experimented on the compressibility of oxygen gas in an apparatus in which the working fluid for transmitting the pressure was mercury. Since the experiments of Regnault it has been commonly assumed that the absorption of the gas by mercury at high pressures and temperatures rendered inexact any such experiments. M. Amagat however finds that the absorption is almost insensible, an oxygen manometer and a nitrogen manometer giving identical indications for several days, even with temperatures varying up to 100°.

MM HAUTEFEUILLE AND CHAPPUIS have continued their researches on the liquefaction of ozone, which they have lately liquefied in the presence of carbonic acid. They believe the point of liquefaction of ozone to be very near that of carbonic acid, and on mixing ozonised oxygen with carbonic acid and submitting it in a capillary tube to a slow pressure at a temperature of $-23°$ (obtained by the evaporation of methylic chloride), they obtained a liquid separated by a distinct meniscus from the gas This liquid was of a clear blue tint, as was the compressed gas above it. If the substance is then allowed to expand gently and immediately compressed, the liquid becomes much more blue, owing to the greater proportion of liquefied ozone The blue tint thus characteristic of ozone under pressure proves it to be present in the gases which result when the silent electric discharge is passed through carbonic acid gas for some hours

EDISON has lately patented a "*webermeter*." This is an instrument for measuring the amount of electric current flowing through a circuit, or in other words a *meter* for electric currents to tell the number of webers that have been supplied. The name is at least in accordance with the inventor's usual abundant ingenuity

IN the *Comptes rendus* M Gouy publishes an extract from a memoir presented by him to the Académie des Sciences, on the propagation of light In this memoir he proposes to examine the particular case of propagation of luminiferous waves, in which, while the direction of the propagation of the movement is constant, the intensity of the waves or of the source of light varies. This problem, which has doubtless been suggested to the author by considerations derived from the photophone, affects the whole question of the measurement of the velocity of light, whether by the methods of occultations of Rœmer and Fizeau, or by that of aberrations (in the rotating mirror), as devised by Foucault The former case only is treated of in M Gouy's paper Setting aside at first the case of dispersive media, and restricting the question to isotropic media, M Gouy investigates mathematically whether the velocity of propagation of the amplitude is the same as that of the wave, and finds that this is the case only for those waves for which the differential equations contain no terms beyond those of the second order—those in which the vibration has virtually attained to the steady condition For such waves moreover in dispersive media the amplitude is not propagated with the same velocity as the waves themselves, but the amplitude itself varies according to a complex function of the wave length according to an ascertainable periodic law. If we remember rightly, a similar hydrodynamic investigation of the rate of propagation of waves in water was made some years ago by Prof Osborne Reynolds, with the result that the effective wave-front only travelled at half the velocity of the steady waves The inference is that that which physicists usually term "the velocity of light" is only the rate of propagation of the wave front, which is slower than the true velocity, the retardation being greatest for the vibrations of greatest wave-length

ANOTHER new property of selenium is claimed as the discovery of M. Blondlot. He states that when selenium is rubbed upon platinum, each metal being connected with a terminal of a capillary electrometer, a current is observed This current, which is observed to pass through the electrometer from the platinum to the selenium, appears therefore to differ from the tribo-electric currents discovered by Becquerel, and which were always in the same direction as the thermo electric currents which would have been produced had the surfaces of friction been directly heated The true thermo electric current of a selenium platinum pair is, according to M Blondlot, from selenium to platinum through the heated junction One curious point stated by M Blondlot is that no indication whatever is obtained upon the capillary electrometer by friction between two metals, or between two insulators, or between a metal and an insulator The electrometer in the selenium experiment indicated a difference of potential about equal to that of one Daniell's cell.

MAGNUS AND TYNDALL found carbonic acid to have a considerable absorbent action on radiant heat. Dr Lecher (*Wien Acad Anz*) has lately made new observations, especially as to absorption of solar radiation by the carbonic acid in the atmosphere. Experiments with a gas lamp and glass cylinder first showed that carbonic acid in a length of 214 mm. gave passage to 94·8 per cent. of the radiation, 536 mm 93·8 per cent , 917 mm 89·0 per cent. At Greifenstein, outside of Vienna (chosen for pure air), the sun's rays also were proved to undergo considerable weakening in passage through carbonic acid gas. A layer of this gas one metre thick absorbed about 13 per cent when the sun had an altitude of 59°, the number however diminished in proportion as the sun got lower This shows that the absorption of solar radiation by carbonic acid is selective, and that the

absorbable wave-lengths become more rare the greater the atmospheric layer the rays have already traversed. The author calculates from his experiments the proportion of carbonic acid in the atmosphere, finding it 3·27 in 10,000 parts by volume; a number agreeing so well with results of chemical analysis as to indicate that this is a good way of determining the carbonic acid in the atmosphere and its variations, applicable, too, at heights where direct measurements are impossible

HERR WINKELMANN proves by experiment (*Wied Ann* No. 11) that the heat conduction of ethylene decreases somewhat with increased pressure The pressure was varied from 10 to 740 mm (Comparative experiments with air showed no influence of pressure) The author explains the phenomenon by the divergence of ethylene from Boyle's law The action of cohesion-forces between the molecules is indicated by that fact, and this will cause, at each collision, a temporary retardation of the straight movements, which effect will occur oftener the greater the number of collisions (*i e* the greater the density) Hence this retardation will increasingly affect the velocity with which two contiguous layers of different temperature exchange the energy of their motions

A REMARKABLE fall of rain in Austria and neighbouring parts on August 11-15 this year, has been closely investigated by Dr Hann (*Wien. Akad. Anz.*), on the basis of data from 260 stations in Austria-Hungary, Bavaria, Switzerland, and Saxony. This fall caused the Danube at Vienna to reach (on the 18th) its highest summer level in this century The rain began in Siebenburgen and south-east Hungary on the 11th, and in general went from east to west It was most extensive on the 12th, and the heaviest fall was in Salzkammergut and neighbourhood The rain-area is found to lie on the west and north-west side of the area of lowest air-pressure, and to stretch westwards far over the border of the minimum region Near the centre of lowest pressure the precipitation was much less than in several parts distant from it The non existence of a minimum producing power of rainfall (contrary to common views), and the incapability of so great rainfall as that in the present case attracting a minimum and influencing its propagation, are noteworthy. The general conclusion arrived at is that no relation is demonstrable between barometric variation and rainfall; the fall of the barometer does not primarily depend on the rainfall, and is not perceptibly influenced by it Dr Hann finds this confirmed by an examination of several other heavy rainfalls in their relation to distribution of air-pressure

THE salt and the ice in cryohydrates have been regarded by Prof Guthrie as in chemical combination In 1877 Herr Pfaundler expressed the view that cryohydrates were merely mixtures of salt and ice. This view is also maintained by Herr Offer, who in a recent paper to the Vienna Academy raises various objections to the existence of cryohydrates as chemical compounds. The numbers expressing the quantities in which the water unites with the salts in various cryohydrates, indicate no stoichiometric law, and tell much rather in favour of chemical mixtures No cryohydrate forms a clear and pure crystal, but always an opaque confused crystalline mass The phenomena which occur when cryohydrates are brought into alcohol and into water are considered to be against Prof. Guthrie's view The heat-absorption of cryohydrates in dissolving, as compared with that of the salt and ice separately, only presents differences which lie within the errors of observation Further, Herr Offer compared the specific gravity of several cryohydrates with those of their constituents, and found pretty close agreement.

FROM recent magnetic researches Herr Auerbach (*Wied Ann.* No. 11) finds the temporary magnetism of cylindrical bodies, *ceteris paribus*, proportional to the mass, greater the greater the length, the less the thickness, the greater the density, dependent only on form, not on size, in the case of nickel, according to density and force, a quarter to half as much as in iron. It increases with magnetising force, first proportionally, then (except with very small density) more quickly, and at last more slowly. The quick increase is greater the denser the body. The turning point is, for the same density, at the same place, but with stronger forces the greater the density, for magnetic saturation of powders extremely strong forces are necessary. Herr Auerbach theorises on these results.

ANOTHER paper on magnetism in these *Annalen* is by Herr Baur, and deals with the "function of magnetisation" for very small magnetising forces; the influence of temperature on it; the magnetisability of iron at very high temperatures; Gore's phenomenon, and the function for varieties of iron. Among other results, the smaller the magnetising force the greater is the influence of temperature on the function in question. Up to a certain force the function increases with increase in temperature, but beyond that it decreases. With weak forces the temporary magnetic moment rises quickly (with rise of temperature) to a maximum at red glow, then sinks quickly to *nil*, with strong forces it gradually sinks, with rise of temperature, to a very low value at red glow. With increased magnetic force Gore's phenomenon becomes more intense and prolonged, and it occurs at a higher glow In ordinary iron the function of magnetisation reaches its maximum very quickly, in iron filings later, and in electrolytic iron very late.

GEOGRAPHICAL NOTES

THE glacier of the Byeloukher Mountain, the chief summit of the Siberian or Great Altay, which has not been visited by men of science during the last fifty years, was recently explored by an expedition engaged in the study of the life of the West Siberian natives After having crossed the 9000 feet high Alps of the Tchouya, the explorers descended into the pretty and wealthy broad valley of the Tchouya, whence, following the Arkhyt River, they soon reached the foot of the mighty Berel glacier The glacier, which forms in its lower parts a *mer de glace* two miles long and 2800 feet wide, was accurately explored and surveyed during a week by the expedition from its lower end to a great ice fall, where the travellers were compelled to stop their work before a moving wall of ice, while mighty masses of snow fell, one after the other, on the glacier from the neighbouring mountains. After having surveyed the glacier and made several drawings of the severe scenery which it affords, the travellers returned to the valley of Ouimon, and thence to the civilised towns

THE astronomical determinations of positions which were made by M Pyevtsoff during his journey from Khobdo through Mongolia to Kalgan, and from Ourga to Kosh agatch, are published by Col Scharnhorst in the last number of the *Izvestia* of the Russian Geographical Society They are most welcome, as they come from a country where exact determinations are very scanty. —The same fascicule of the *Izvestia* contains M. Larionoff's catalogue of seventy-five determinations of heights in the northern and eastern parts of the province of Kouldja and in the mountains which border it north and ea t, and M Severtsoff's map of his route on the Pamir Rang-koul, south-east of the Lake Kara-koul.

THE Russian travellers who have been engaged in the exploration of Central Asia are now returning to St Petersburg Col. Prshevalsky is expected every day, and the Russian Geographical Society, at its last meeting (December 15), elected the indefatigable traveller an Honorary Member M Potanin is already at St. Petersburg, and will soon give a lecture on his journey to Western Mongolia, as also M Pyevtsoff, who travelled with merchants from Biysk to Khou-khou khoto, and who during his journey collected much material for the correction of the map of Mongolia M Mushketoff, who has explored the glacier of Zarafshan (NATURE, vol xxiii p 44), gave a lecture at the last meeting of the Russian Geographical Society on his excursion. This traveller, contrary to M. Severtsoff's experience, did not find in the Thian-Shan any traces of the glacial period

THE *Kouban News* announces the appearance, in the Sea of Azoff, of a new little island, some 150 feet in diameter, and 10 feet above the level of the water Its appearance was accompanied with a kind of marine eruption. It is 150 brasses distant from the shore, where a crevice has appeared.

THE organisation of the Polar meteorological station on the Lena is being actively carried out by Prof. Lentz The director of the station will be M Yurgens.

PROF. NORDENSKJOLD is again thinking of fresh enterprises. At present a ship is being built at the Lena estuary, in which he intends to start on a new Arctic expedition in the summer of 1882

PRINCE BORGHESE, the Italian African traveller, has arrived near Tripolis from Wadai. This is the first time that a traveller from Darfur has reached the Mediterranean by way of Wadai and Bornu.

THE Leipzig publishing firm of Ferd Hirt and Son announce that Major Serpa Pinto's great African work of travel will be published in January, 1881.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

ALFRED C. HADDON, B.A., Scholar of Christ's College, Demonstrator of Comparative Anatomy, and Curator of Zoology in the University of Cambridge, has been appointed Professor of Zoology at the Royal College of Science, Dublin.

THE movement to found a college at Dundee has been revived, and at a meeting last week it was announced by Dr. Baxter, the Procurator Fiscal, that he was in a position to place 125,000*l.* at the head of a subscription for the purpose. Owens College, Manchester, is proposed as the model of the Dundee Institution.

DURING recent years much has been done in Russia by private initiative for primary education in natural science. Now we notice the creation at St. Petersburg of a special institution, the aim of which is to devise and collect apparatus and drawings for the teaching of natural science in primary schools. A special collection of objects intended for the illustration of science will be sent from school to school by the Committee, and lectures will be given in each school on the subject.

THE building of the new Siberian University is being briskly carried on. It will contain twenty large rooms for lectures, as well as spacious halls for the museum and library. The building for anatomy, as well as the hospital for clinical medicine, will be erected in accordance with the latest hygienic principles. A special building will be appropriated for the physical cabinet and the astronomical observatory.

THE Moscow University is closed for an indeterminate time because of the disturbances among medical students, and three hundred students are incarcerated in the town prison.

SCIENTIFIC SERIALS

Journal of the Franklin Institute, December.—Boiler experiments, by Mr. Isherwood.—New electric motor, by Mr. Griscom.—The Sawyer electric light.—Proceedings of Institute, &c.

Bulletin de l'Académie Royale des Sciences de Belgique, Nos. 9 and 10.—Influence of liquids on the sound of sonorous bells which contain them or which are immersed in them, by M. Montigny.—On the chemical composition of the epidote of Quenast, by M. Renard.—On Caels and De Bennie, by M. Mailly.

No. 11.—On the compensation of a chain of geodetic triangles, by M. Adan.—Excretory apparatus of Trematodes and Cestodes (3rd paper), by M. Fraipont.

Rivista Scientifico Industriale, No. 21, November 15.—On spherohedry in crystallisation, by Prof. Bombicci.—On beats, the third sound of Tartini, &c. (concluded), by Dr. Crotti.

No. 22, November 30.—On some singular phenomena of geometrical optics, by Prof. Cassani.

Reale Istituto Lombardo di Scienze e Lettere. Rendiconti, vol. xiii. fasc. xvii., November 11.—On *Peronospora viticola* and the cryptogamic laboratory, by Prof. Garovaglio.—On measurement of the thermo-luminous radiations of the sun, by Dr. Chistoni.—Fourth series of researches and studies on the pelagic fauna of the Italian lakes (short *résumé*), by Prof. Pavesi.—The leprosy of Ancient Italy, especially of Comacchio, by Prof. Sangalli.

Kosmos, September 1880, contains:—Theodor Vuy, on the rehabilitation of shattered authorities; considerations on the education of the future.—Dr. Ernst Krause, sketch of the development history of the history of development, No. 3.—Dr. H. Muller, on the variability of alpine flowers.—Leopold Einstein, apprehension and comprehension, a study in the philosophy of language.—Short notices and extracts from journals. Literary and critical notices.

October.—Prof. Fritz Schultze, the transformation of human fundamental conceptions on the threshold of modern times.—Prof. Dr. Hornes, on phacops and dalmanites, genera of trilobites and their probable genetic connection.—George Potonié, on the purport of the stony particles to be found in the flesh of the pear and generally in the Pomaceæ.—Dr. Fritz Muller, *Paltostoma torrentium*, a gnat with two forms of females, one with a mouth for honey-sucking the other with a mouth for blood-sucking (with illustration).—Short notices and extracts from journals. Literary and critical notices.

SOCIETIES AND ACADEMIES

LONDON

Chemical Society, December 16.—Prof. H. E. Roscoe, president, in the chair.—The following communications, &c., were made:—On the estimation of nitrogen by combustion, including the nitro-compounds, by J. Rufile. The author recommends the use of the following mixture instead of soda lime in the process of Will and Varrentrapp:—Two molecules of sodium hydrate, one molecule of pure lime, and one molecule of sodium hyposulphite, the substance before burning being mixed with about its own weight of a mixture of sulphur and wood charcoal. By this process good results were obtained with sodium nitrate, picric acid, &c.—Dr. Carnelly then showed some experiments as to the effect of pressure in raising the melting-points of ice, camphor, and mercuric chloride. By suspending a cylinder of ice (formed round the bulb of a thermometer) in a Torricellian vacuum and condensing the aqueous vapour by a freezing mixture, so as to keep the vacuum perfect, the author has raised ice to 180° C. before it melted. In the experiment shown, through an accident, the temperature only rose to 30° C. before the cylinder fell off the thermometer. Camphor which was boiling in a tube solidified when the pressure was diminished, though the heating was continued. Mercuric chloride, which under diminished pressure had been raised considerably above its melting-point, melted and boiled as soon as it was exposed to atmospheric pressure.—On some naphthalene derivatives, by Dr. Armstrong and Mr. Graham.

Geological Society, December 15.—Robert Etheridge, F.R.S., president, in the chair.—William Elijah Benton, Rev. George Clements, J. Kerr Gulland, Francis T. S. Houghton, George Bingley Lake, and William Mansell MacCulloch, M.D., were elected Fellows, and Prof. Luigi Bellardi of Turin, and Dr. M. Neumayr of Vienna, Foreign Correspondents of the Society. The following communications were read:—On the constitution and history of grits and sandstones, by John Arthur Phillips, F.G.S. In the first part of this paper the author described the microscopic and chemical structure of a large series of grits, sandstones, and in some cases quartzites, of various geological ages, noticing finally several sands of more or less recent date. The cementing material in the harder varieties is commonly, to a large extent, siliceous. The grains vary considerably in form and in the nature of their inclosures, cavities of various kinds and minute crystals of schorl or rutile not being rare. The author drew attention to the evidence of the deposition of secondary quartz upon the original grains, so as to continue its crystal structure, which sometimes exhibits externally a crystal form. This is frequently observable in sandstone of Carboniferous, Permian, and Triassic age. Felspar grains are not unfrequently present, with scales of mica and minute chlorite and epidote. Chemical analyses of some varieties were also given. The author then considered the effect of flowing water upon transported particles of sand or gravel. It results from his investigations that fragments of quartz or schorl less than one fiftieth of an inch in diameter retain their angularity for a very long period indeed, remaining, under ordinary circumstances, unrounded; but they are much more rapidly rounded by the action of wind. It is thus probable that rounded grains of this kind in some of the older rocks, as, for example, certain of the Triassic sandstones, may be the result of Æolian action.—The chair was then taken by J. W. Hulke, F.R.S., V.P.G.S.—On a new species of *Trigonia* from the Purbeck beds of the Vale of Wardour, by R. Etheridge, F.R.S., president, with a note on the stratigraphical position of the fossil by the Rev. W. R. Andrews. In this paper the author described a species of *Trigonia* discovered by the Rev. W. R. Andrews in the "under-bed" of the Middle Purbeck series in the Vale of Wardour. The specimens were found in the railway-cutting one mile west of Dinton Station. The shell was referred to d'Orbigny's section "Glabræ" of the genus *Trigonia*, and named *Trigonia densinoda*. In its ornamentation it closely resembles *T. tenuitexta*, Lyc., of the Portland oolite, but is more depressed and lengthened posteriorly, and destitute of the antecarinal space which occurs in all known Jurassic "Glabræ." The escutcheon is remarkably large, and possesses transverse rugæ, as in the Neocomian "Quadratæ." The author regarded the species as a transition form connecting the two groups of *Trigoniæ* above-mentioned. The description of the new species was accompanied by a note on the Purbeck strata of the Vale of Wardour by the Rev. W. R. Andrews.

Meteorological Society, December 15.—Mr. G. J. Symons, F.R.S., president, in the chair.—J. Coventry, J. W. Moore,

M.D, W. T. Paulin, J. Porter, and Capt. W. C Smith were elected Fellows —The following papers were read —Report on the phenological observations for the year 1880, by the Rev T. A Preston, M.A., F M.S Agriculturally speaking the year may be considered as disappointing Till June the weather was such as has rarely been experienced for farm operations. The severe cold of the winter broke up and mellowed the soil, and the dry open weather enabled farmers to clean their land from the excessive growth of weeds caused by the damp of the year before The dry May was not favourable for the hay, which suffered severely in some places, but still a crop with far more real nourishment in it than would be obtained from a rank growth would have been secured had it not been for the terrible floods of July in the Midland Counties, which not only seriously injured the crop, so that it was frequently not worth the trouble of removing off the land, but also carried it entirely away in low-lying districts The corn again, which was looking most promising till July, suffered much during that damp period, and had it not been for the subsequent fine weather would have been ruined. But the unfavourable season of 1879 produced very serious effects on vegetation, especially on trees and shrubs and their produce. The young wood of the trees was not ripened, and as a natural consequence the severe winter killed an enormous quantity of some kinds, and greatly injured others "Laurustinus" was generally killed to the ground, and in some districts the destruction of other shrubs was severely felt. The evergreens in many cases lost large quantities of their leaves. Hollies especially are mentioned by several observers, and privet-hedges were sometimes quite leafless With respect to fruit-trees, apples and pears in some localities (but not all) were hardly able to put forth any bloom, and the crops were consequently extremely poor Wall-fruit was also a general failure, but this was partially owing to severe weather when the trees were in bloom, for in some instances the show of bloom was splendid Gooseberries and currants produced enormous crops, and strawberries were very fine, but they lasted an unusually short time Seeds generally ripened with difficulty; much of the corn could not be ground, and a great deal was mixed up with roughly-ground Indian corn and flavoured to induce the cattle to eat it. The crop of ordinary garden seeds was also far below its usual quality, and some of the favourite garden flowers were consequently very poor Among the *special* features of the year may be mentioned the great quantity of certain insects "Aphis" was in astonishing numbers in the early part of the year The apple-shoots, before the leaves expanded, were in almost every case covered with the "green fly," and among wild plants the Mealy Guelder-rose was especially attacked by them. "Wasps," again, have been in extraordinary numbers, and dreadful accounts of them have been sent to the various entomological periodicals, their numbers appear to have exceeded all previous experience The larvæ of the gooseberry moth and of the gooseberry saw-fly have also been extremely destructive, and finally, as an undoubted result of the wet season of 1879, the larvæ of the crane fly have been a perfect plague in some localities, and sheep licks in others. The scarcity of small birds has been universally noticed, some, no doubt, perished from the cold, but vast numbers had migrated The enormous numbers of larks which hastened to the Eastern Counties on the outbreak of cold weather was astonishing.—On the variations of relative humidity and thermometric dryness of the air, with changes of barometric pressure at the Kew Observatory, by G M. Whipple, B.Sc, F.R.A S —On the relative frequency of given heights of the barometer readings at the Kew Observatory during the ten years 1870-79, by G M Whipple, B Sc, F R.A.S.

Mineralogical Society of Great Britain and Ireland, December 23 —Prof M. Forster Heddle, F.R S E, president, in the chair —Prof. F. J Wiik of Helsingfors was elected a corresponding member, and Messrs Baxter, Gray, James Cunningham, R. Shaw Simpson, H. B Guppy, and Stephen Vivian as ordinary members —The following papers were read and discussed:—On Tyreeite, by the President.—On minerals new to Britain, by the President —Note on Gilbertite, and on tin pseudomorphs from Belowda Mine, by J. H Collins.—On Brochantite and its allies, by William Lemmons —On a remarkably fine crystal of Euclase, by L. Guyot —On the action of organic acids on minerals, by Prof. H. C Bolton —Note on artificial Gay-Lussite, by C Rammelsberg —Note on a peculiar carbonaceous substance from the Maesymarchog Colliery, by James S. Merry.

Anthropological Institute, December 14.—Edward B. Tylor, F R.S, president, in the chair.—The election of the Rev R A. Bullen as a member of the Institute was announced. —Mr W. St Chad Boscawen read a paper on "Hittite Civilisation"

Institution of Civil Engineers, December 21.—W. H. Barlow, F R S., president, in the chair —The scrutineers reported that the following gentlemen had been duly elected to fill the several offices in the Council for the ensuing year.—Mr. James Abernethy, president; Sir W G Armstrong, C B, F R.S, Sir J W. Bazalgette, C B, Mr. F. J Bramwell, F R S., and Mr J. Brunlees, vice-presidents; Mr. G. Berkley, Mr. G B Bruce, Sir John Coode, Mr. E. A. Cowper, Mr. A. Giles, Sir Charles A. Hartley, Mr. H. Hayter, Dr W. Pole, F.R S, Mr R Rawlinson, C B, Mr. A. M Rendel, Dr. C. W. Siemens, F R.S, Mr D Stevenson, Sir W Thomson, F R.S., Sir Joseph Whitworth, Bart, F.R.S., and Mr. E Woods, other members of Council.

EDINBURGH

Royal Society, December 20 —Sir Wyville Thomson, vice-president, in the chair —Mr John Aitken read a paper on dust, fogs, and clouds, which we give on another page. —Mr E Sang communicated a note on the solar eclipse of December 31, 1880, which is visible in our islands.—Dr Marsden, in a paper on the preparation of adamantine carbon, intimated that he had at length effected the crystallisation of carbon in the cubical form The crystals he had obtained were however far too minute to be of any commercial value —Prof Blyth described an electric sonometer, consisting of a wire monochord, which, traversed by an interrupted electric current, was set into strong vibrations between the poles of a horse shoe magnet. The notes given out were loudest when they were harmonics of the fundamental interrupted note which was sounded by a vibrating tuning-fork inserted in the circuit—Dr Haycraft communicated an explanation of the amœboid motions of masses of protoplasm, illustrating his theory by an extremely simple mechanical contrivance An india rubber ball perforated with several small apertures was filled with coloured white of egg, and immersed in a solution of sugar of about the same density as the albumen When a gentle pressure was applied, the albumen was forced out in long continuous processes, and when the pressure was relaxed the processes at once retracted inside the ball again, probably in virtue of the action of the viscosity and surface-tension of the gelatinous matter Thus was explained the retraction of the amœboid processes, after they had been expelled by contraction of the internal muscular structure.

THURSDAY, JANUARY 6, 1881

DR. GUNTHER ON FISHES

An Introduction to the Study of Fishes. By Albert C L G Gunther, M A, M D, Ph D, F R S, Keeper of the Zoological Department in the British Museum (Edinburgh, A and C Black, 1880)

A GENERAL work on Fishes could not have been undertaken by a more thoroughly qualified writer than Dr Gunther Twenty years ago and more he commenced studying the collection of this ever-interesting and most important group in the vaults of the British Museum, with what success let not only the present fine collection of fish in the National Museum declare, but also that truly wonderful work, to be the product of one man's labours, "The Catalogue of Fishes," in eight volumes, published by order of the Trustees of the British Museum Fishes have always been a subject of great interest to mankind, their commercial value interests some, others, as keen sportsmen, could not exist without their finny prey, from the earliest times, and among the earliest records, we find them of importance as articles of food To the man of science, be he or be he not a specialist, fishes are of an ever-increasing interest, placed at the very beginning of vertebrate life, and by their study we seem to see more clearly into the evolution of that life which culminated in the production of ourselves

A book to tell us in carefully selected generalities all about fishes such the English reader had no access to, until the publication of this volume If it come not up to a perfect standard how could it be otherwise, for had not the history of the structure of fish, their habits, their distribution, their classification to be condensed within the limit of a few hundred pages, and the wonder is that so much will be found here given, not that a few things have been left unnoticed or but partially touched upon We have looked over each page of the handsomely got-up, well-printed, and well-illustrated volume, and we feel certain that it must find a place on the shelf of all biologists, and that it will find a place in the libraries also of that vastly larger class, the intelligent general reader

The first and slightly smaller half of the volume treats of fishes in general, the second half of fishes from a systematic and descriptive point of view The work opens with an account of the history and literature of the subject beginning with Aristotle, who had a perfect knowledge of the general structure of fish, and who wrote about them some three and a half centuries before the Christian era, which account is continued to the most recent times, the work done by Ray, Artedi, Linneus, Bloch, Lacépède, Cuvier, Agassiz, Muller, being passed in review The next twelve chapters treat of the external morphology of fish and of their internal structure. We would have liked more details about the recent researches into the modifications to be met with in fishes' tails; the description of the electrical organs to be met with in some fish is far too brief, the myology of fishes is dismissed with a little over a page, as if it were not a favourite subject with the author, and yet it is one worth working at and by no means deficient in promise In the chapter on Respiration the subject of the temperature in fishes is scarcely alluded to; the chapter on the Reproductive Instincts of Fish is sure to interest the readers, some of whom may learn for the first time of female fishes taking care of their progeny, and more curious, of male fishes doing the same The chapter on the Growth and Variation of Fishes is well illustrated by woodcuts of some remarkable changes of form in fish The fourteenth chapter treats of domesticated and acclimatised fishes, on the artificial impregnation of ova, tenacity of life and reproduction of lost parts, hybernation in fishes (a misuse of this term), useful and poisonous fishes The uses of fishes to man our author disposes of in twelve lines, and it would almost seem as if he would rather not have referred to such a subject at all in the scientific part of this treatise In these twelve lines we find the following - "In the Polar regions *especially* whole tribes are *entirely* dependent on this class for subsistence" Without venturing on criticism we would ask, Is this so? Do the inhabitants of the Polar regions support their life wholly on fish, or are they not indebted for a large portion of their heat-producing food to the flesh or blubber of mammals? and do not the inhabitants of tropical countries, on the contrary, manage often to support their existence almost entirely on fish food?

While the chapters concerning the distribution of fishes in time leave a good deal to be desired, those on the distribution of fishes in space are most excellent, that on the fishes of the deep sea contains a complete list of deep-sea forms with the depths as ascertained by the dredgings of the *Challenger*, which list contains apparently over 100 species. Before the voyage of the *Challenger* scarcely thirty deep-sea fishes were known Though this number has been now so very much increased yet no new types of families have been discovered Perfectly novel and very interesting modifications of certain organs have been met with, but nothing more than what might have been expected from our previous knowledge of the group The greatest depth reached hitherto by a dredge in which fishes were inclosed is 2900 fathoms, but the specimens then obtained belong to a species (*Gonostoma microdon*), which would seem to be extremely abundant in the upper strata of the Atlantic and Pacific Oceans and were very probably caught by the dredge in its ascent The next greatest depth, 2750 fathoms, must be accepted as one at which fishes undoubtedly do live The fish obtained at this depth in the Atlantic, *Bathyophis ferox*, showing by its whole habit that it is a form living on the bottom of the ocean

"The fish fauna of the deep sea," writes Dr Gunther, "is composed chiefly of forms or modifications of forms which we find represented at the surface in the cold or temperate zones, or which appear as nocturnal pelagic forms" The Chondropterygians are few in number, not descending to a depth of more than 600 fathoms The Acanthopterygians, which form the majority of the coast and surface faunas, are also scantily represented; genera identical with surface types are confined to the same inconsiderable depths as the Chondropterygians, while those Acanthopterygians which are so much specialised for the life in the deep sea as to deserve generic separation, range from 200 to 2400 fathoms Three distinct families belong to the deep sea fauna, viz Trachypteridæ, Lophotidæ, and Notacanthidæ, they

respectively consist of three, one, and two genera. Gadidæ, Ophidiidæ, and Macruridæ are very numerous, ranging through all depths, they constitute about one-fourth of the whole deep-sea fauna. Of Physostomi, the families of Sternoptychidæ, Scopelidæ, Stomiatidæ, Salmonidæ, Bathythrissidæ, Alepocephalidæ, Halosauridæ, and Muræmidæ are represented. Of these the Scopeloids are the most numerous, constituting nearly another fourth of the fauna. Salmonidæ are scarce, with three small genera only Bathythrissidæ includes one species only, which is probably confined in its vertical as well as horizontal range, it (*Bathythrissa dorsalis*) occurs at a depth of about 350 fathoms in the sea of Japan The Alepocephalidæ and Halosauridæ, known before the *Challenger* Expedition from isolated examples only, prove to be true, widely spread, deep-sea types Eels are well represented, and seem to descend to the greatest depths; Myxine has been obtained from a depth of 345 fathoms

In the systematic portion Dr Gunther divides the class of fishes into four sub-classes the first Palæichthyes, the second Teleostei, the third Cyclostomata, and the fourth Leptocardii The description of each order, sub-order, and family is given In addition we have the diagnosis of all the more important genera, and under these are given the names of the species of economic value or special scientific interest. We select the following account of two interesting genera as examples taken from the eighth family of the sharks, Spinacidæ —

"ACANTHIAS—Each dorsal fin with a spine Teeth equal in both jaws, rather small; their point is so much turned aside that the inner margin of the tooth forms the cutting edge Spiracles rather wide, immediately behind the eye

"The two species of 'Spiny Dog Fishes,' *A vulgaris* and *A Blainvillii*, have a very remarkable distribution, being found in the temperate seas of the Northern and Southern Hemispheres, but not in the intermediate tropical zone They are of small size, but occur at times in incredible numbers, as many as 20,000 having been taken in one season on the Cornish coast They do much injury to the fishermen by cutting their lines and carrying off their hooks

"CENTROPHORUS—Each dorsal fin with a spine, which however is sometimes so small as to be hidden below the skin, mouth wide, teeth of the lower jaw with the point more or less inclined backwards and outwards, upper teeth erect, triangular, or narrow, lanceolate with a single cusp, spiracles wide, behind the eye.

"Eight species are known from the southern parts of the European seas and one from the Moluccas, they do not appear to exceed a length of five feet According to the observations of E. P Wright some of the species at least live at a considerable depth, perhaps at a greater depth than any of the other known sharks. The Portuguese fishermen fish for them in 400 to 500 fathoms with a line of some 600 fathoms in length The sharks caught were specimens of *Centrophorus cælolepis*, from three to four feet long, the sharks as they were hauled into the boat fell down into it like so many dead pigs, there was not the smallest motion of their bodies. There can be no reasonable doubt that they were inhabitants of the same great depth as Hyalonema, and that in fact they were killed by being dragged to the surface from the pressure of water under which they lived The dermal productions of some of the species have a very peculiar form, being leaf-shaped, pedunculate, or ribbed or fronded with an impression."

One other quotation must suffice; the Clupeidæ forms the twenty-second family of the Physostomii, which is the fourth order of the second sub-class; after enumerating several genera, among them Engraulis, to which the Anchovy belongs, the hint being given that "lucrative fisheries of Anchovies might be established in Tasmania, where the same species occurs, in Chili, China, Japan, California, at Buenos Ayres, each of which countries possesses Anchovies by no means inferior to the Mediterranean species," the author proceeds to give the particulars of the genus Clapea. After the scientific description he adds —

"This genus comprises more than sixty different species The majority are of greater or less utility to man, but a few tropical species (*C thrissa*, *C. venenosa*, and others) acquire probably from their food highly poisonous properties so as to endanger the life of persons eating them The most noteworthy species are —

"1 *C harengus* (the 'Herring') It is readily recognised by having an ovate patch of very small teeth on the vomer. Gill cover smooth without radiating ridges It inhabits in incredible numbers the German Ocean, the northern parts of the Atlantic, and the seas north of Asia. The herring of the Atlantic coasts of North America is identical with that of Europe A second species has been supposed to exist on the British coast (*C Leachii*), but it comprises only individuals of a smaller size, the produce of a late or early spawn. Also the so-called 'Whitebait' is not a distinct species, but consists chiefly of the fry or the young of herrings, and is obtained 'in perfection' at localities where these small fishes find an abundance of food, as in the estuary of the Thames

"2 *C mirabilis* The herring of the North Pacific

"3. *C sprattus* The 'sprat,' without vomerine teeth. Gill cover smooth, without radiating ridges. Abundant on the Atlantic coasts of Europe

"4 *C. thrissa* One of the most common West Indian fishes, distinguished by the last dorsal ray being prolonged into a filament Hyrtl has discovered a small accessory branchial organ in this species

"5. *C. alosa* The 'shad' or 'Allice shad,' with very fine and long gill-rakers, from sixty to eighty on the horizontal part of the outer branchial arch, and with one or more black lateral blotches Coasts of Europe, ascending rivers

"6 *C finta* The 'shad' or 'Twaite shad,' with stout osseous gill-rakers from twenty one to twenty-seven on the horizontal part of the outer branchial arch, and spotted like the preceding species Coasts of Europe, ascending rivers and found in abundance in the Nile

"7. *C menhaden* The 'mossbanker,' common on the Atlantic coasts of the United States The economic value of this fish is surpassed in America only by that of the Gadoids, and is derived chiefly from its use as bait for other fishes and from the oil extracted from it, the annual yield of the latter exceeding that of the whale (from American fisheries). The refuse of the oil factories supplies a material of much value for artificial manures.

"8 *C sapidissima* The American shad, abundant and an important food-fish on the Atlantic coasts of North America. Spawns in fresh water

"9 *C. mattowocca* The 'Gaspereau' or 'Ale-wife,' common on the Atlantic coasts of North America, ascending into fresh water in early spring and spawning in ponds and lakes

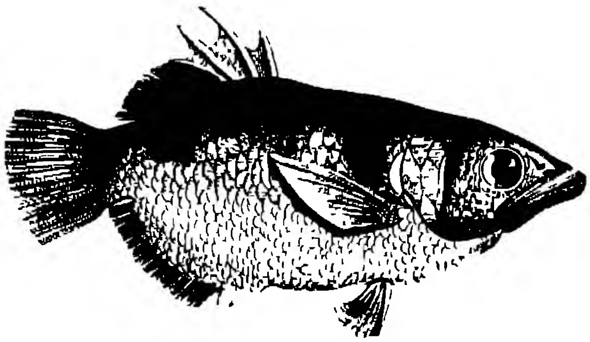
"10 *C pilchardus*. The 'Pilchard' or the 'Sardine,' equally abundant in the British Channel, on the coast of Portugal, and in the Mediterranean, and readily recognised by radiating ridges on the operculum, descending towards the sub-operculum

"11 *C sagax* Representing the Pilchard in the Pacific, and found in equally large shoals on the coasts of California, Chili, New Zealand, and Japan.

"12. *C. toli.* The subject of a very extensive fishery on the coast of Sumatra for the sake of its roes, which are salted and exported to China, the dried fish themselves being sent into the interior of the island. The fish is called 'Trubu' by the Malays, is about eighteen inches long, and it is said that between fourteen and fifteen millions are caught annually.

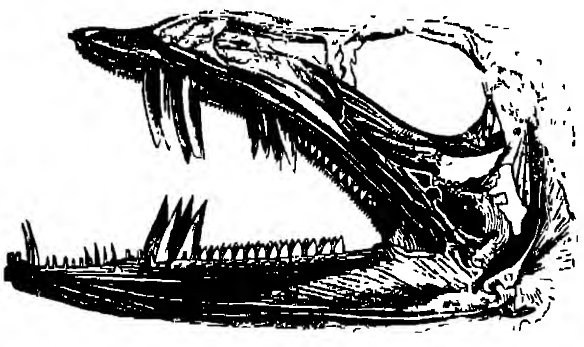
"13. *C. scombrina.* The 'oil sardine' of the eastern coast of the Indian Peninsula."[1]

These quotations will show the value and importance as well as the interest of the systematic and descriptive part of this volume, not a page of which is without some



Toxotes jaculator

lines of most instructive reading, in many cases sufficiently so as to tempt one to turn "Ichthyologist" on the spot. We strongly recommend the reader to turn at once to the pages on the Salmonidæ. This portion too is illustrated with many excellent figures, two of which, through the courtesy of the publishers, we are permitted to reproduce—the first is of a fish belonging to the genus Toxotes. Two species of this genus are known from the East Indies, one of which (*T. jaculator*) is the more common, and it ranges to the north coast of Australia. It has received its name from its habit of squirting a drop of water at an insect which it perceives close to the surface in order to



Skull of *Plagyodus ferox.*

make it fall into it. The Malays, who call it "Ikan sumpit," keep it in a bowl in order to witness this singular habit, which it continues even in captivity.

The second woodcut represents the bones of the head of one of the largest and most formidable of the deep-sea fishes. Of the genus Plagyodus but one species is known (*P. ferox*). It has been found off Madeira and in the sea off Tasmania. Other species have been noticed from Cuba and from the North Pacific, but it is doubtful if they differ specifically from *P. ferox.* The fish grows to a length of six feet, and from the stomach of one specimen have been taken several eight-armed cuttle-fish, Crustacea, Ascidians, a young brama, twelve young boar fishes, a horse-mackerel, and one young of its own species. The stomach is coecal, the commencement of the intestine has extremely thick walls, its inner surface being cellular, like the lung of a reptile, it has no pyloric appendage. All the bones are extremely thin, light, and flexible, containing very little earthy matter. Very singular is the development of a system of abdominal ribs symmetrically arranged on both sides and extending the whole length of the abdomen. Perfect specimens are rarely obtained on account of the want of coherence of the muscular and osseous parts, caused by the diminution of pressure when the fish reaches the surface of the water. The exact depth at which *Plagyodus ferox* lives is not known, probably it never rises above a depth of 300 fathoms, but woe betide any rash intruder that dares to descend into the realms of its abyss.

The volume closes with some directions for collecting and preserving fishes—when practicable fishes when dead should be set to swim in spirit. But we must not quote any more, so leave the curious reader to find out the details of how, having caught his fish, he can cook it so as to make it of value for some national museum.

[1] In this quotation the fin formulæ and references to works on the Herring, &c., are omitted.

SULPHURIC ACID AND ALKALI

A Theoretical and Practical Treatise on the Manufacture of Sulphuric Acid and Alkali, with the Collateral Branches. By George Lunge, Ph.D., F.R.S.E., Professor of Technical Chemistry at the Federal Polytechnic School, Zurich (formerly manager of the Tyne Alkali Works, South Shields). Vol. III. (J. Van Voorst, 1880.)

THE publication of the third and concluding volume of Prof. Lunge's excellent work follows wonderfully soon on that of the first and second. This volume, which fully equals the other two in accuracy of description and clearness of style, is devoted to the subsidiary processes lying alongside of the main channel of Leblanc's great discovery. We first find a chapter on the ammoniacal soda process now rising, through Solvay's exertions, into well-merited and formidable competition with its older rival. The ash made by this theoretically beautifully simple and practically most original process is very pure, containing from 98 to 99 per cent. of Na_2CO_3, and free of course from the impurities common to Leblanc's ash of caustic soda and sulphide of sodium.

But this Solvay's ash is less dense than that made by the old plan, and both German and English manufacturers are now making a Leblanc ash of 98 per cent. free from sulphur and of a dense quality. The struggle, says Lunge, is not now one of purity, but merely of price, and so far Leblanc soda is holding its own. Here however the beneficial action of competition is seen: if Messrs. Brunner, Mond, and Co., of Northwich and Sandbach, were not turning out from 35 to 40 tons of Solvay ash *per diem*, I cannot help thinking that the Leblanc soda-makers might have felt inclined to rest content with their previous performances. There is of course no chance of this new process turning out the old-fashioned plan until the chlorine of the common salt can by this new method

be made available as a marketable article. At present it runs away as calcium chloride, but if Weldon's process for regenerating the chlorine were to prove as successful as his well-known plan (of world-wide application) for obtaining it from the ordinary chlorine-still liquor has proved (and this so far has not come to pass), it is pretty clear that all the old alkali works would have to be closed. Next come the chapters on Bleaching Powder and Chlorate of Potash Here we find thirty-four pages of a practical treatise devoted to the theoretical consideration of the composition of bleaching powder, and even graphical formulæ may be detected on some of these pages, to say nothing of chemical equations of some complexity, involving the discussion of one of the most intricate of chemical problems This is a pretty dish to set before our "typical practical man," who only knows the substance he makes under the names of "B P" or "Chemic," and would be puzzled to say of what it consisted. It is however a species of nourishment which it will do him good inwardly to digest, for if he turns away from it in disgust and dismay, so much the worse for him and his manufacture. "The rule of thumb," as Mr Mundella truly said at Leeds the other day, "is now over, we stand at its grave." Our manufacturers must all be thoroughly trained in the scientific principles which underlie their trades. Noble and great things have been done by Englishmen in the perfection and development of chemical industry, and still greater things remain for them to do, but whilst taking only proper credit for what England has done and is doing, let us not forget that the general scientific education of our manufacturers and managers is far below that of their Continental competitors It is no doubt quite true that no German alkali work could exist were it not for their import duty on English soda, for even with all their care and scientific knowledge, the Germans are unable to compete on equal terms with us, thanks rather to the circumstances of our environment than to any special merits of our own

But this artificial and economically unsound condition of Continental manufacture ought rather to urge us so to complete our system that we not only shall have the advantages which geographical position and geological good fortune places at our disposal, but also that thorough scientific training and the knowledge of what is being done elsewhere, without which all natural advantages become comparatively valueless In this way and in this way only can we, as it seems to me, fight against the incubus of protective tariffs On this necessity for our typical "practical man" to re-consider his position and to arm himself for the technical war with every appliance which science places at his disposal, Dr Lunge speaks so forcibly and so well in the preface to his third volume that I take the liberty of giving his remarks *in extenso*.

I may however express my own doubts whether the British alkali-maker has, as Dr Lunge maintains, in reality been distanced by any foreign manufacturer of alkali or sulphuric acid, except so far as regards the import of British goods into countries where inland production is artificially stimulated by protection. As regards other chemical industries, especially those such as the manufacture of colours, in which great delicacy and care in manipulation and an intimate knowledge of the highest developments of organic chemistry are essential, one must in sorrow confess that Dr. Lunge is perfectly right when he says that the English trade is rapidly passing into the hands of French and German houses.

"Other books aim at nothing but giving an accurate description of the present style of making sulphuric acid and alkali in England; and they leave the chemistry of the subject almost totally aside My treatise differs from this in several respects. First it gives a detailed chemical description of the raw materials, intermediate and final products, of the modes of testing, and so forth, supplemented by numerous tables of solubilities, densities, &c, and it also enters very fully into the theory of all the processes concerned, accurately citing all papers on the subject, so that the reader can go to these for further elucidation I am quite aware that a treatment of this kind will appear lengthy and superfluous to some readers who look into this book merely for 'practical' hints. In this respect they will not, I trust, be disappointed either, but I make bold to say that they would do very well not to despise the scientific part, the purely chemical detail, of this work

"After all, our subject belongs to the domain of *chemistry*, and the times are far behind us when, in the manufacture of chemical products, the practical man with his rule of thumb could look down upon the chemist in the laboratory—who in the former's idea was at best only good for testing the materials, but whose interference with the works would invariably cause mischief That this was true to some extent, and still is so, where the chemist attempts to transfer his ideas into practice in a crude state without sufficient practical experience, nobody can possibly deny. But does the 'practical man' on his part make no mistakes?

"Have not untold sums been wasted in futile 'inventions' and 'improvements' merely because 'practical' inventors lacked a scientific knowledge of their subject? Probably very much larger sums have been lost in this way than by the deficiency in practical experience of 'theoretical' inventors, for the simple reason that the latter class of inventors generally have not so much means at command as the former It is a mere truism that theory and practice should always go hand in hand, but it must nevertheless be inculcated over and over again, as would appear from the fact that several costly books on perhaps the most important branch of chemical industry have just been published with next to no chemistry in them And to what consequences does this neglect of a scientific treatment of practical subjects lead? The author may be pardoned for illustrating this from his personal experience. A little more than sixteen years ago he left his native country for Great Britain, and he might justly hope to learn a great deal and find much more scope for himself in that country which he is proud to have made his second home. More particularly the manufacture of sulphuric acid, soda-ash, and bleaching-powder was at that time quite insignificant in Germany, and not very considerable in France as compared with Great Britain, nor could the technical appliances, the yields, or even the purity of the products in the two former countries vie with those of the latter. How different matters are now is a matter of notoriety The manufacture of chemicals has made enormous strides forward, both in quantity and quality, in France, and even more so in Germany. Many of the chemicals of these countries outstrip those of English works in purity; and their plant and their processes are frequently superior to those used in the majority of English works. Everybody knows how this has come about. The foreign chemists and manufacturers have looked all round, not merely in their own countries, but wherever they could find improved methods and apparatus, and upon the practical knowledge thus gained

they have brought to bear the scientific training they had received at their universities and polytechnic schools Thus they have already, in many fields formerly remunerative to British manufacturers, distanced the latter, immensely aided though these be by their long occupation of the ground and by permanent natural advantages, such as cheapness of coal and of freight, superior command of capital, &c., and this is likely to go on to an increasing extent if many British chemical manufacturers decline to profit from a scientific study of their respective branches This is all the less excusable, as England from of old has been a stronghold of scientific chemistry, and can hold its own against the whole world in that respect"

To these words I will only add that one of the best possible signs of advancement in the study of science so necessary for the permanent well-being of our manufactures would be to find well-thumbed copies of Dr Lunge's three volumes not only on the alkali-maker's shelves, but in the house of every manager, and on the table of every free library in the manufacturing districts.

H E. ROSCOE

OUR BOOK SHELF

Aide-Mémoire du Voyageur Par D Kaltbrunner (Zurich Wurster et Cie, 1881)

THIS is a sort of supplement to the "Manuel du Voyageur" by the same author, noticed in these pages at the time of its appearance The present volume may be described as a collection of constants in all departments of science likely to be of service to the scientific traveller, and indeed to students of many kinds It contains a series of sections in geography (mathematical, physical, and political), geology, biology, and anthropology To each section is prefixed a list of works to be consulted on the particular subject, numerous plates and maps, an index, and a table of authors whose works are cited. The whole work seems to us well put together, the information really useful, and, so far as we have tested, trustworthy, though the lists of works are not always so complete as they might be, this can be easily amended in subsequent editions To all interested in geography in its widest sense, the work must prove of real service

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts No notice is taken of anonymous communications*

The Editor urgently requests correspondents to keep their letters as short as possible The pressure on his space is so great that it is impossible otherwise to ensure the appearance even of communications containing interesting and novel facts.]

Geological Climates

I SHOULD not say more on this subject, but that the last paragraph of Mr Starkie Gardner's letter seems to imply that I have adopted some of his views without acknowledgment. Now I certainly read his article in NATURE of December 12, 1878, with much interest and profit, but, as regards the special question of the cause of the mild climates of Eocene and Miocene times, I entirely disagreed with his views, as is sufficiently shown by my recent letter in NATURE I quite admit that the closing up of the North Atlantic between Europe and North America *might* have considerably raised the temperature of Britain, but it would just as certainly have rendered the Arctic regions even colder than they are now, by shutting out the Gulf Stream, whereas all the evidence points to *continuous* mild Arctic climates through Cretaceous, Eocene, and Miocene times Again, though I admit that there has probably, on more than one occasion during the Tertiary period, been a land connection between North-West Europe and North-East America, yet the peculiar distribution of the Tertiary mammalia of Europe and North America indicates that such connection was exceptional, and only endured for very short periods, the rule being a separation like that which now exists I could therefore only have quoted Mr Gardner's view to disagree with it, and I did not think it advisable to encumber the exposition of my own theory with more references of this kind than were absolutely necessary. I may add, that the extension of the Miocene Arctic flora to Grinnell Land since Mr Gardner's article appeared, renders his views still more untenable. Of course I here refer to my chapter on "Mild Arctic Climates" in "Island Life" In my letter to NATURE I confined myself strictly to the point raised by Prof Haughton, which I did not consider had been adequately met by Mr Gardner's hypothesis.

ALFRED R. WALLACE

Is your correspondent, Mr Ingram of Belvoir Castle, quite certain that he has not confused the *Araucaria Cunninghami* of Queensland with *Cunninghamia lanceolata* of China? The names are misleading

Temperature of the Breath

FROM time to time during the past few months letters on "the temperature of the breath" have appeared in NATURE, and some conjectures have been advanced regarding the cause of the high temperatures produced by breathing on thermometers enveloped in silk or other materials

One of the correspondents supposes that the high temperature thus produced indicates a cooling action of the breath The refrigerating agency of respiration by the heating of respired air and by evaporation from the lungs is sufficiently well known, and has been calculated by Helmholtz, but it is scarcely logical to ascribe to the breath a temperature so obviously produced by the intervention of another agent, and this hypothesis would involve the rejection of all observations hitherto made by physiologists on the temperature of the breath and of the blood

A few lines which appeared in NATURE of October 7 indicated what appeared to me to be the simple and philosophical explanation (*i e* hygroscopic condensation) of the phenomenon under discussion The higher temperatures produced in dry than in wet weather, and by some materials than by others, distinctly point to the hygroscopic state and nature of the material as the modifying influences

The question is entirely physical, and not physiological Wrapping the thermometer is a new factor in taking the temperature of the breath, and is, *primâ facie*, the cause of the high temperature Some further experiments which I have just completed place the matter beyond all doubt Not to occupy your space with unnecessary details, I give only an outline of them —

1 A current of air directed upon the bulb of a naked thermometer caused no appreciable rise neither did the mercury rise when the bulb was enveloped in silk, but when it was enveloped in *dried* silk it rose several degrees (The silk was dried by heat, and allowed to cool in a stoppered bottle)

2 Three thermometers—(1) bulb naked, (2) bulb wrapped in silk, (3) bulb wrapped in *dried* silk—placed in a current of *hot damp* air for some minutes, marked respectively 116°, 120°, and 123° F

3 Two thermometers, one naked, the other wrapped in silk, were placed in a flask, with their stems passed through the cork The flask was then immersed in hot water (about 150° F) The naked thermometer rose rapidly, the covered one very slowly After twenty minutes the temperature of the water was 120°, and the naked thermometer marked 112°, while the covered one registered only 108°.

4 Two thermometers, one naked, the second wrapped in dried silk, were fixed in a flask as for last experiment, but a little water was placed in the flask, which was then plunged into hot water as before The naked thermometer rose rapidly at first, but it was soon outstripped by the covered one The following was the result after some minutes —Water, 128°, naked thermometer, 118°, covered thermometer, 136

5. Two thermometers, one naked, the second enveloped in dried silk, were passed through a cover fitting a glass vessel which was carefully dried and heated, and the cover was cemented on to prevent the passage of moisture from the air. After an hour the naked thermometer had cooled to 81° (temperature of air), and the covered one to 83° They were then changed to a similar vessel containing a little water, the

covered thermometer rose rapidly till it nearly touched 94°, while the naked one remained stationary.

The conclusions to which these experiments point are too obvious to require demonstration. C. J. McNally

Madras, December 9, 1880

Selenium

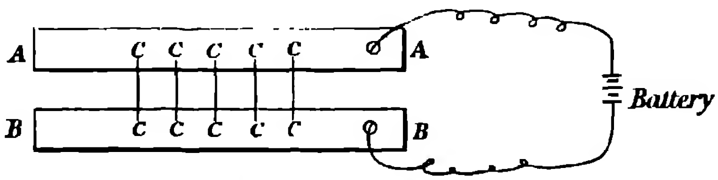
The use of selenium in the photophone has suggested to me the possibility of using it in two ways, which I shall now describe, thinking you may perhaps consider them of sufficient general interest to publish in Nature.

Firstly, it seems probable that selenium might be used to obtain the automatic registration in a chronograph of such phenomena as star transits. It possesses the property of being drawn into fine wire at a low temperature, but whether it can be drawn fine enough to represent transit wires in a telescope I do dot know.

The arrangement would be as shown in the diagram, where A A B B are parallel metal plates crossing the field of the telescope, and insulated from each other except by the selenium wires C C C C in one direction, and by a wire circuit passing through a battery, and a relay, R, in the other. The relay should be so adjusted that the increased force of the current passing through the circuit caused by the light of a star falling on each wire C C in succession, shall cause its armature to act, and pass on a signal to the chronograph.

The delicacy of the adjustment required for this purpose might be a greater difficulty than I am aware of; but it should be borne in mind that the length of selenium in the circuit may be very small, as the plates A A B B need not be farther apart than sufficient to insure the star's falling between them without excessive accuracy of setting, say one-twentieth to one-tenth of an inch in a telescope of moderate size. If necessary, it would be simple enough to give each wire C C its own distinct circuit. Should the brittleness of the wires prove a difficulty, they may be supported between the plates A A B B in any convenient way which does not interfere with the insulation of these plates.

The second purpose would perhaps be of more practical use than the above, viz. to secure an automatic daily time-signal.



Let a thin plate of selenium be placed between, and in firm contact with, two parallel plates of metal, which are connected with each other by a wire passing through a battery and a relay as above, so that the selenium alone interrupts the circuit. Then if this plate be placed with its length in the meridian, and a lens adjusted above it, so as to throw the image of a star, or the sun, as it crosses the meridian exactly on the selenium, a signal will be obtained from the relay as before, which in this case may be the stroke of a bell or any other convenient sound.

An ordinary lens would require constant changes of adjustment if used for the sun, moon, or any body of varying declination, but if the lens were the central slice cut out of a sphere by two small circles parallel to each other and equidistant from the centre, placed with its flat sides parallel to the meridian, while the selenium was placed in a curve concentric with that of the lens, at the proper distance from its surface, and of sufficient length—of course being accurately in the meridian—then any heavenly body of whatever declination—between certain wide limits—would throw its image on the selenium and afford a signal, if of sufficient brightness. The arrangement of a warning-signal would be easy.

If this method proved practicable the objection would remain of having to apply a correction to obtain mean time, which would probably prevent its being used for public purposes, such as dropping time-balls or firing time guns. It seems to me however that it might nevertheless prove very useful to many private individuals who require an accurate knowledge of time.

Poona, December 3, 1880 W. M. C.

Experiments with Vacuum Tubes

At a meeting of the Philosophical Society of Glasgow on December 22, 1880, I gave a very brief preliminary account of some experiments that I have been making, along with Sir William Thomson, with vacuum tubes. We have sealed up English and German glass tubes with very high vacuums, but without any electrodes, and have obtained very remarkable luminous effects both with the Ruhmkorf coil and also working by means of electrostatic induction. Using an ordinary frictional electric machine, and applying one end of a long vacuum tube to the prime conductor, while the other end of the tube is held in the hand, the tube becomes charged as a double Leyden jar in the following way:—one end of the tube, next to the prime conductor,—outside positive, inside negative, the other end—inside positive, outside negative. This can be shown by the gold leaf electroscope. The charges seem to be very high and the glass is very frequently perforated. Indeed it is difficult to work with the electric machine in tolerably good order without perforating the glass. While this double Leyden jar is slowly discharged, by removing, part by part, the charges from the outside of the tube, beautiful luminous effects are observed very different from those seen in the ordinary vacuum tubes. We have also obtained curious effects by heating the middle region of the tube so highly that it becomes a semi-conductor. J. T. Bottomley

Physical Laboratory, University, Glasgow, December 29

Modern Use of Ancient Stone Implements

Perhaps the following statement will interest some of your readers:—In an old volume, "Thomae Bartolini Acta hafniensia," Ann. 1674, 1675, 1676, I find a paragraph signed by Olaus Borrichius, which clearly indicates that in the seventeenth century ancient stone implements, and probably many of them, were converted into flints for the use of the contemporaneous musquetry. The text runs thus:—"Silices Anholdini triangulares. Insula haec [Anholt in the Kattegat] porrigitur in sinu codano, minuta illa quidem et naufragiis multorum infamis, uno hic laudanda quod si quis arenas littoris ejusdem scrutetur, infinitos reperiat silices nigros, albos, varios, in sabulo hinc inde sepultos, ad sex transversos digitos in longitudinem protensos, latos digitum unum, omnes triquetros ac si manu artificis fuissent acuminati, et lateribus plerumque in illam aciem excitatis, ut Iosuae servire potuerint cultris saxeis filiorum Israel circumcisionem imperanti. Nunc ferreo hic seculo in alios vocantur usus: malleo enim in frusta convenientia divisi sclopetorum rotulis ignem prompte ministrant et fomitis incendiarii loco fulmineis bellatorum tubis ancillantur." D. Budde

Rome, December 26, 1880

Pile Dwellings

If the connection between pile dwellings in the Swiss lakes, the Swiss châlet, and the Malayan modern pile dwellings is demonstrated, a decided advance has been or will be made in prehistoric anthropology.

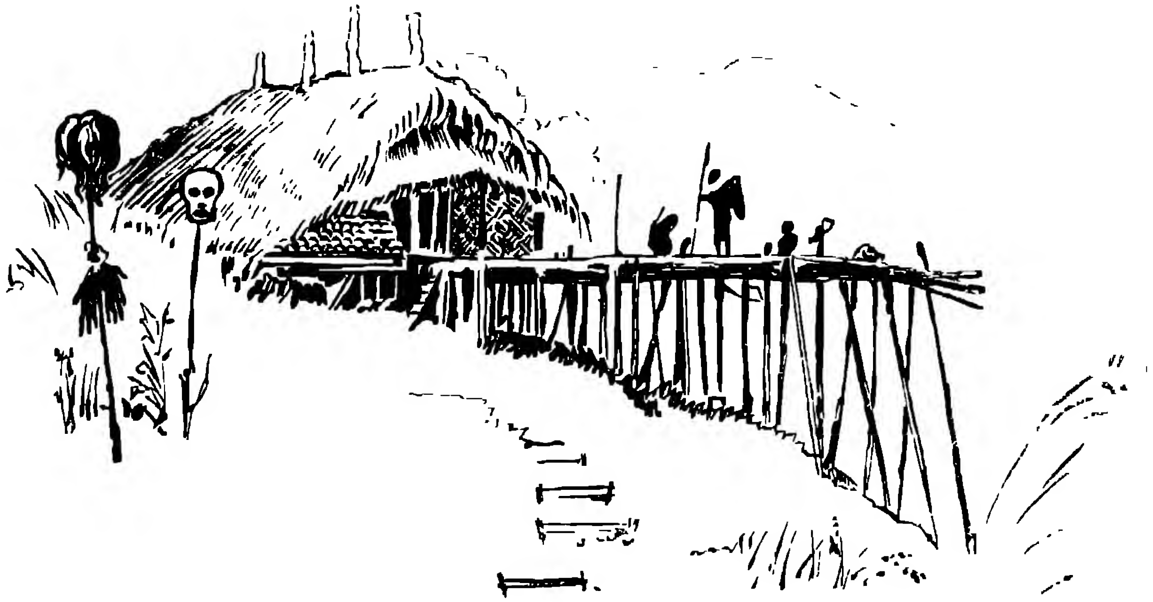
Pile dwellings are a very distinct characteristic of all the Hill races north east of Bengal, except those on the Kasia Hill ranges, and so far as I can see is a conspicuous distinction between the Aryan and non-Aryan races here.

The persistence with which this custom is retained among tribes who have migrated to new sites, where the need is not obvious, seems to offer a safe means of tracing to some extent racial descent or relationships.

The "Miris" of Asam offer a case where part of the tribe is still in its hills, while the rest are more or less scattered along the Brahmaputra in the level land of Asam, and build houses alike. The Ahoms, a Shan race who invaded and settled in Asam in A.D. 1228, built pile dwellings, and the "Deodhaings," who are lineally descended from them, do so now. The Butias

Daflas, Akas, Abors, Mishmis, Singphus, and Nagas (all) build pile-dwellings, as do the Kamtis

Several peculiarities are noteworthy, *i.e.* that the custom is confined to *hill races*, and not seen in plain races, that the invariable explanation offered to inquiry is that on the hill tops and spurs, where *alone* the villages are built, there is very little



level land; also that this form of house is a necessity among races that keep pigs and goats, which to any casual visitor is at once obvious

As it is possible that this question may afford unexpected results when examined, I inclose sketch of a Naga "Morang," or skull house, which with its platform is the same as those they live in Different tribes have variations of the pattern, and most have the platform balcony in some shape or other, and the posts go through the roof in some Nagas houses alone

Asam S. E. PEAL

Landslips.—The Cheshire Subsidences

UNDER the guidance of Mr. Thos Higgin, F L S., and your correspondent Mr Ward, I have just been examining the subsidences that have been lately taking place in the neighbourhood of Northwich To understand how they occur, it is necessary to know that there are two beds of rock salt in the Triassic marl. The upper bed, 25 yards thick, is from 40 to 60 yards below the surface, the lower, 35 yards thick, is separated from the upper by about 10 yards of hard marl The greater bulk of the salt is obtained in the form of brine pumped up from the upper bed. The lower bed is to a smaller extent worked as a salt-mine. From these operations two classes of subsidences result; the one general and gradual, due to the removal in solution of the rock salt of the upper bed by percolation of water and pumping, by which the surface of the ground sinks in undulations, the other, sudden fallings in of the ground into the mines, forming crater-like pits. It is to these I wish to call attention I was fortunate enough to see one before it had become, as they all do, partially filled with water I should judge it to be about 70 feet deep, 150 feet diameter at the top, and 20 or 30 feet at the bottom, where a little water was lodging The problem to account for is how such an inverted cone of marl capped with boulder-clay and drift-sand could apparently have disappeared through so small a hole? The explanation appears to be this By percolation of water the roof of the mine begins locally to give way and fall into the mine, gradually working its way to the surface, where it first appears in the form of a hole about the size of a well. The vacuity will no doubt take a conical form, the base being at the roof of the mine, once the hole is formed, the surface ground begins to slip and fall in around, gradually enlarging the orifice, the material disappearing into the mine below. This continues until the bottom is filled up and the sides of the "crater" attain the angle of repose. The whole thing will occur in a night. The subsidences certainly present a very remarkable appearance from the regularity of their circular or elliptical form and funnel crater-like shape. It is evident such subsidences could not happen except under special conditions, such as are provided by salt-mining and pumping in these Keuper marls. T MELLARD READE

Park Corner, Blundellsands, Liverpool, December 22, 1880

Animal Reasoning

I SEND an account of a singular act of animal intelligence which may not be uninteresting to the readers of NATURE. A lady, a friend of mine, was at one time matron of a hospital for poor women and children which was maintained by subscription. One of the inmates was a blind girl who was there not as a patient, but temporally till a home could be found for her She had learned to feed herself, and at meal times a tray containing her dinner was placed on her knees as she sat in a comfortable chair for her special convenience in feeding herself One day while she was eating, the pet cat of the establishment placed herself before the girl and looked long and earnestly at her, so earnestly that the matron, fearing the animal meditated some mischief to the girl, took her out of the room Again the next next day, at the same hour, the cat entered the room, but this time walked quietly to the girl's side, reared herself on her hind legs, and noiselessly, stealthily reached out her paw to the plate, selected and seized a morsel that pleased her, and, silently as she came, departed to enjoy her stolen meal The girl never noticed her loss, and when told of it by her companions laughed very heartily

It is evident that the cat from observation had entirely satisfied herself that the girl could not see, and by a process of reasoning decided she could steal a good dinner by this practical use of her knowledge. K P

Cambridge, Massachusetts

Ozone

THE letter of J. P. on this subject hardly gives enough data to enable one to found an opinion upon, but is it not possible the paper is coloured by ozone from the air? It is well known that a flame is the most potent method of collecting atmospheric electricity, and a properly-insulated spirit flame ignited in dry air seldom fails to show some traces. I would suggest the experiment being repeated on the exposed plate of a gold leaf electrometer, the surrounding conditions of place, air, &c, being noted - also under a bell glass, where such conditions would be varied. Ozone is very strong just now, my paper this morning reaching 10, the limit of Negretti and Zambra's scale. J. RAND CAPRON

Guildown, December 28, 1880

THE INDO-CHINESE AND OCEANIC RACES—TYPES AND AFFINITIES[1]

II.

A BELIEF in sorcery is very general, especially amongst the Melanesians, and some of the practices associated with it often resemble those prevalent amongst the Australians and African Negroes, and even in mediæval times in Europe In Tanna, New Hebrides group, Dr G Turner tells us that the real gods "may be said to be the disease-makers It is surprising how these men are dreaded, and how firm the belief is that they have in their hands the power of life and death There are rain-makers and thunder-makers, and fly- and mosquito-makers, and a host of other 'sacred men', but the disease-makers are the most dreaded It is believed that these men can create disease and death by burning what is called *nahak* Nahak means rubbish, but principally refuse of food Everything of the kind they burn or throw into the sea lest the disease-makers should get hold of it These fellows are always about, and consider it their special business to pick up and burn, with certain formalities, anything in the nahak line that comes in their way. If a disease maker sees the skin of a banana, for instance, he picks it up, wraps it in a leaf, and wears it all day hanging round his neck. The people stare as they see him go along, and say to each other, 'He has got something, he will do for somebody by and by at night' In the evening he scrapes the bark off a tree, mixes it with the banana skin, rolls up tightly in a leaf in the form of a cigar, and then puts the one end close enough to the fire to cause it to singe, and smoulder and burn away gradually Presently he hears a shell blowing 'There,' he says to his friends, 'there is the man whose rubbish I am now burning, he is ill Let us stop burning and see what they bring in the morning'

"When a person is taken ill he believes it is occasioned by some one burning his rubbish Instead of thinking about medicine he calls some one to blow a shell, which, when perforated and blown, can be heard two or three miles off The meaning of this is to implore the person who is supposed to be burning the sick man's rubbish and causing all the pain to stop burning, and it is a promise as well that a present will be sent in the morning The greater the pain, the more they blow the shell, and when the pain abates they cease, supposing that the disease-maker has been kind enough to stop burning Then the friends of the sick man arrange about a present to be taken in the morning Pigs, mats, knives, hatchets, beads, whales' teeth, &c, are the sort of thing taken. Some of the disease-making craft are always ready to receive the presents and to assure the party that they will do their best to prevent the rubbish from being again burnt If the poor man has another attack at night he thinks nahak is again burning. The shell is again blown, and so they go on, and if he dies his friends lay it all down to the disease-makers, as not being pleased with the presents taken and as having burned the rubbish to the end. The idea is that whenever it is all burned the person dies" ("Nineteen Years in Polynesia") Substitute for the nahak a waxen image of the absent victim, and you have in this account a perfect parallel to the belief in the power of witchcraft to injure at a distance universal at all times in Europe:—

> "Devovet absentes, simulacraque cerea fingit,
> Et miserum tenues in jecur urget acus."
>
> (Ovid, *Epist* 6)

But this merely shows how little reliance can be placed on similarity of manners and customs in tracing the affinities of races The mind of man having sprung, as seems most probable, from one original centre, is everywhere very much the same in the infantile or undeveloped stage Hence, like practices under like conditions may very well arise independently in diverse places without implying any ethnical relationship or even any necessary social contact The most extravagant theorist would scarcely venture to suggest any direct relationship of any sort between the Papûans, for instance, and the Basques, yet amongst the young girls of both races the extraordinary taste for making pets of little pigs prevails At least the practice is spoken of by recent explorers as common in New Guinea, while Mdme. d'Aulnoy ("Relation du Voyage d'Espagne," Paris, 1691) was greatly surprised to find the young Basque ladies of Bayonne indulging in the same habit when she visited the place in 1679 "Some of those who came to see me had a little sucking-pig tucked under their arms, just as we carry our little lap-dogs. Several had ribbons of different colours tied round their necks as collars But when the ladies joined in the dance they were obliged to let the horrid beasts loose in the room, where they made more noise than so many imps." The "couvade" is another remarkable custom attributed both to the Basques and to the Buru Islanders, Eastern Archipelago, in common with many other peoples ancient and modern in the Old and New World But M Julien Vinson (*République Française*, January 19, 1877) has shown that, at least as far as regards the Basques, there is little or no ground for the statement We all know what astonishing conclusions as to ethnical affinities certain ethnologists have drawn from the assumed common prevalence of this eccentric fashion amongst the most widely-dispersed nations Yet even if it did exist amongst them such conclusions would be otherwise inadmissible

It may be mentioned that the missionaries have been for some years at work amongst the Mafôr people and their kinsmen of Dorey, into whose language they have translated several tracts and portions of Scripture Here is a specimen from Genesis i 1 ('In the beginning," &c). "Beponeia kaku man-eren allah ibejadi nanggi ma dûnya Dûnya ibeurba ma ibro beri, ma ifnuiep kôn ro bo i, ma rûi manseren allah bieda inob ro bo wâreya." The Malay, or rather Arabic words, *allah*, God, *dûnya*, earth, *rûr* for *rûh*, spirit, are of course borrowed by the translator, but the structure of the language is entirely different, being highly agglutinating and employing both pre- and post-fixes, like other Papûan dialects. In other respects the Papûan and Melanesian tongues differ so profoundly from each other that it is impossible to group them in one linguistic family As a rule they possess absolutely nothing in common beyond a certain uniformity of structure and such verbal resemblance as is due to Malay and Sawaiori influences These influences are very wide-spread, as shown especially in the numerals, which the dark races have almost everywhere borrowed from their brown and olive neighbours But they often still retain the old quint system at one time common to Indo-China and Malaysia, but in the Oceanic area now mostly replaced by the decimal Thus in the Duke of York Islands, between New Britain and New Ireland, the five first numerals only are taken from the Sawaiori or Eastern Polynesians, the numbers beyond five being expressed by addition, as in Cambojan and several Malayan and Western Papûan dialects Hence for the Samoan *e ono* = six, *e sefulu* = ten, we have *limadi ma ra* = 5 + 1, *limadi ma limadi* = 5 + 5, where *limadi* is from the Samoan or Eastern Polynesian *lima* = 5 By an analogous process the numerous Sawaiori words that have found their way especially into the Eastern Papûan idioms are always compelled to conform to the agglutinating character of Papûan grammar. Thus the Fijian and Duke of York *tama* = brother, apparently answering to the Samoan *tama* = boy, assume the pronominal postfixes *zu*, *g*, *na*, &c, peculiar to those groups, the Fijian *tamazu* and Duke of York *tamag* being equivalent to the Samoan *o lo'u tama* = my brother or my boy Here we

[1] Continued from p 203

clearly see how entirely the structure of the Papûan differs from that of the Sawaiori tongues, and how constant is the law that languages of different systems may borrow any number of words from each other, while each invariably retains its own grammatical genius Hence, when we hear of mixed Papûan, Malayan, and Sawaiori tongues in these regions the expression is always to be understood as referring to the vocabularies only, never to the grammar or structure of those languages In philology there is no rarer phenomenon than mixed grammatical systems, though perhaps it might be premature to deny the absolute possibility of such mixture

III. THE AUSTRAL RACES *Australians, Tasmanians* (?)

The area occupied by this division of the dark races is limited to the Australian continent and neighbouring island of Tasmania. Here we enter an entirely new ethnical world, for, although the extinct Tasmanians betray certain doubtful affinities to the Melanesians, the Australians stand quite apart. They are usually represented as black, straight-haired, dolichocephalous, and prognathous But this general description can pretend to no scientific accuracy, and in any case it is extremely doubtful whether they can be regarded as all belonging to one original stock. Topinard, who has devoted great attention to the subject, recognises at least two distinct aboriginal types, the fusion of which results in the average Australian as above described, and whose essential peculiarity may be said to consist in the combination of more or less negroid features with straight hair The more primitive race, found mainly on the low-lying coast tracts about King George's Sound, in the north-west and extreme east, is described as of short stature, very black and prognathous, with woolly or at least frizzly hair, the second and finer race, occupying the interior, and especially the north-eastern highlands, are much taller, of lighter colour, with straight or wavy hair, and slight prognathism

But, notwithstanding these discrepancies, Brough Smith well observes that "throughout Australia the natives exhibit a general conformity to one pattern as regards features, colour, and mental character A man from Southern Gippsland [Victoria] would be recognised as an Australian by the inhabitants of Port Essington, and a native of King George's Sound would be surely known if taken to York Peninsula" This common racial instinct or fellow-feeling is perhaps our best justification for treating as an independent ethnical group a people for whom affinities have been sought far and wide, by Huxley with Logan in India, by others in Polynesia, Egypt, Europe, or America. One of the arguments adduced in support of an Egyptian or Indian relationship is based on the assumed resemblance of the throwing-sticks of those peoples with the Australian womguine or boomerang, but Brough Smith ("The Aborigines of Victoria," i p 323), who has gone thoroughly into this question, concludes that "it is safe to deny the affinity of the Dravidian or Egyptian boomerang with that of the Australian native, because the first, under no circumstances whatever, could be made to behave as the womguine does The flat leaf-like weapon of the Australian differs essentially from the Egyptian crooked stick" Much reliance is also placed on a certain resemblance between the Dravidian and Australian systems of kinship. But when we find that L. H. Morgan discovered a somewhat similar system prevailing throughout the North American tribes, and that the Rev Lorimer Fison was able to extend its domain to the South Sea Islanders, we begin to attach less importance to a character of this sort *Quod nimis probat nihil probat* was a sound maxim amongst the schoolmen

The Australian languages, which, with great differences, present a remarkable uniformity of structure and phonetics throughout the continent, have also been compared with the Semitic, Aryan, and other systems, but with no results, except where the unscientific method has been adopted Thus *murry*, great, is compared with the Keltic *mor*, or the English *more*, *cobbera*, head, with the Spanish *cobra*, quite a modern formation, *gibber*, rock, with the first syllable of *Gibraltar*, of which the true Arabic form is *Jebel*, *hieleman*, shield, with the Anglo-Saxon *helian* or *heligan*, to cover, or with the English *helmet*, which the ingenious etymologists are careful to tell us is "a little shield for the head", *cabohn*, good, with the French *bon*, *tiora*, land, with the Latin *terra*, *kirafi*, wizard, with the Greek χειρουργός, *ruwi*, country, with the Latin *rus*, *takkin*, eating, with the English *take in* (why not *tuck in* ?), *marli*, limestone, with *mortar*, beyond which it would be difficult to carry etymological eccentricity. Many of these languages are highly agglutinating, some even verging on true inflection, but scarcely any have distinct names for the numerals beyond 1 and 2, after which $3 = 2 + 1$, $4 = 2 + 2$, and so on

This common feature alone should be sufficient to reject any Semitic, Aryan, or Dravidian affinities, for if the Australians came of any of those stocks, it is not to be believed that all the tribes would have agreed to forget their inherited arithmetical system, and stop short precisely at the inconveniently low numeral 2 At the same time it is conceivable that at an extremely remote age, while Australia still formed part of the Asiatic mainland, tribes resembling the Korumbas, Maravars, Todas, and other low-caste peoples of the Deccan, may have spread southwards and here amalgamated with others of a Papûan type from Melanesia The result of such an intermingling might be a race not unlike the present average Australian—dark, prognathous, more or less dolichocephalous and with wavy or shaggy hair intermediate between the frizzly and straight But these migrations cannot have taken place since the subsidence of the land, because none of the races in question are navigators, although some of the New Guinea tribes have recently learnt the art from the Malays On the other hand the remoteness of the period to which such movements must be referred is no objection, for Australia has been peopled for many ages, as is evident from the vast kitchen-middens found on the coast, and some of which have already been used as manure by the white settlers

The extremely low estimate of the Australian intellect formed by Mr Wake and other ethnologists seems at least somewhat premature, and no one can turn over the pages of Brough Smith's great work on the Aborigines of Victoria without coming to the conclusion that the race has been much vilified and unduly depreciated by careless or superficial observers Many instances are given of their skill even in drawing, a capacity for which was wholly denied them They often show great quickness in adapting themselves to the ways of the white man, and the children constantly show themselves "quite as capable of receiving and profiting by instruction as the children of untaught parents among the white race" (*op cit* ii p 256). It was recently stated that the native school at Coranderrk, on the Yarra, had gained relatively more passes than any other school in Victoria.

At the same time most of the tribes are addicted to extremely revolting practices, those by which the "coming of age" is celebrated being especially barbarous and disgusting Some also, under unfavourable conditions, have either sunk to, or never risen from, the most debased condition compatible with existence Mr. Taplin was acquainted with a Narrinyeri family, "residing on Lake Alexandrina, the members of which were as nearly brutes as they could be. They subsisted on roots and native fruits, and such fish and game as came into their hands by means of the simplest contrivances, the thrown waddy, or the simple noose, and they were regarded by their own people as very low They would not even make a shelter, but cowered under bushes and in holes; and yet it could not but be evident how far they were

above the brute. The man could make twine, the woman a rush basket" (*op. cit.*, p. 10)

Cannibalism has also been prevalent, assuming amongst some tribes a very revolting form.

Unfortunately not many of the Aborigines are left to benefit by the enlightened and humane system of treatment tardily introduced by the local administrations There are probably not 30,000 left in all Australia; even those of Victoria, who are best cared for, are dying out except in a few favoured stations, and "Lalla Rookh," the last of the pure blood Tasmanian women, died in June, 1876 The Tasmanians differed in many important respects from the Australians They were of darker colour and considerably less dolichocephalous, with decidedly frizzly hair, this latter feature bringing them into close connection with the Melanesians. In point of culture they stood almost on the lowest level, possessing no fixed abodes, wearing no clothes, never cultivating the land, unacquainted with the rudest arts, possessing neither domestic animals, pottery, nor the boomerang or bows and arrows of the Australians. They were divided into a great number of tribes, speaking as many as nine quite distinct languages, but so little developed that the sense was largely eked out with the aid of gesture and signs Yet their cranial capacity seems to have been slightly greater than that of their neighbours (index 80 as compared with 78), while they were nearly as orthognathous as Europeans. These contradictions constitute the Tasmanian a type *sui generis*, allied partly to the Australian, partly to the Melanesian and Polynesian, with some special features which may perhaps be due to their long isolation from other races.

B—CAUCASIAN TYPE

IV CONTINENTAL BRANCH. *Khmêr or Cambojan Group*

In Further India, with one exception, all the settled peoples forming recognised nationalities, that is, the Burmese, Thai or Siamese and Annamese, are physically of Mongolian stock, and all speak languages of the monosyllabic or isolating class The same is largely true of the Mishmis, Khasias, Kukis, Nagas, Khyengs, Karens, and other wild tribes in the west and north-west, as well as of the Shans, Mou-tz', and many Miau-tz' tribes in the north Hence the universal assumption that, excluding Malacca, all the inhabitants of the peninsula constitute one ethnical and linguistic group allied to the Chinese in the north and to the Tibeto-Himalayan races of the north-west, and with them forming collectively the great South-Eastern division of the Mongolian family This comfortable theory was first shaken by the revelations of the famous French expedition of 1866-8 up the Me-Khong River, since when the writings of Dr Thorel, Francis Garnier, E Aymonnier, C E. Bouillevaux, Dr Harmand, and other French naturalists have made it abundantly evident that there is in this region an important non-Mongolian element, which must henceforth be taken into account. Yet so slowly does scientific truth make its way against long-established error, that the fact has scarcely yet been recognised in any comprehensive treatise on ethnology or linguistics In a paper prepared for the meeting of the British Association in Sheffield in 1879, and since published in separate form,[1] I endeavoured to determine the true nature of this non-Mongolian element, and to point out its essential importance in connection with the classification of all the Indo-Chinese and Oceanic races It was there shown that the Khmêr or Cambojan nation, the exception above referred to, together with a large number of kindred peoples inhabiting the Lower Mekhong basin and the region between that river and the Coast range running from Cape St James northwards to the Chinese frontier, form a distinct racial and linguistic group, of the same physical type as the Mediterranean or Caucasian races of the west, and closely akin to the brown Oceanic races of Malaysia and the Pacific

The arguments brought forward in support of this view need not here be formally repeated, and it will be sufficient to vindicate the use of the term "Caucasian" as thus extended to the remotest Polynesian islands It has been objected that there are no Aryan languages in the far east, and that the Eastern Polynesians are a brown race, consequently that the word Caucasian cannot here apply. But those who so argue seem scarcely to realise the nature of the problem Caucasian is not a linguistic, but an ethnical expression, hence although the Aryan, Basque, Semitic, and many languages of the Caucasus have no conceivable relationship with each other, we do not hesitate to regard those who speak these languages as of one stock because their physical type is substantially the same. This type we conventionally call Caucasian or Mediterranean, which terms must be held to apply wherever the physical features implied by them are found, irrespective altogether of the language question Why speech and type should not correspond is another problem, which admits of an obvious solution, but which cannot here detain us.

The objection based on colour, though more to the point, is scarcely more forcible The brown Polynesians are not supposed to spring directly from the fair Europeans, but to have gradually spread from Indo-China through Malaysia to their present homes, and it will be presently seen that there are peoples in Indo-China brown enough to suit the Polynesian taste, and fair enough to claim kinship with the western nations. Besides, the question of colour must anthropologically be regarded as altogether of secondary importance There are black Caucasians in Abyssinia, deep brown Caucasians in the Ganges Valley, dusky or swarthy Hamites and Semites, also Caucasians, in North Africa and Arabia, and why may there not be brown Caucasians in Polynesia? Surely the evolutionist, who does not hesitate to accept the development of the *genus homo* from some anthropoid ape, need not scruple about the relationship of the human species because of such a secondary matter as colour Schweinfurth tells us that albinism is common amongst the negroes of the Nile basin, and there is at the present moment a clear case of melanosis in London If these be regarded as morbid symptoms, they are often hereditary, and it has not yet been shown that they may not be cases of atavism, such as the reappearance of the bars on the pigeon's wing, however far removed from the original blue-rock type *Nimium ne crede colori*, wisely said Linnæus, speaking of plants, and the remark is equally applicable to the animal kingdom Observing that the black pigment does not make its appearance on the Negroes of Loango, West Coast of Africa, until after birth, the Berlin anthropologist Falkenstein suggests that it may be due to the action of the solar rays If so, what becomes of colour as a fundamental characteristic at all?

Besides the civilised Khmêrs, forming the bulk of the present kingdom of Camboja and neighbouring Siamese provinces of Ongkar and Battambang, the chief Caucasian peoples of Indo-China are the Chams, Charays, Bolovens, Stiêngs, Suê, Xong, Cedangs, Rhoedehs, Banhars, Samrê, Lemets, and Kûys, the last of whom are looked on by the Cambojans as the primitive Khmêr stock; hence are called by them *Khmêr dom*, or "original Khmêrs" In the paper above referred to the physical characteristics of these tribes are thus summed up mainly from Thorel —"A fine, vigorous race, with symmetrical and well-set frames, stature rather above the middle size, straight profile, oval face, dolichocephalous head, high forehead, retreating very slightly, black hair, often inclining to brown, straight or wavy and elliptical in section,

[1] "On the Relations of the Indo-Chinese and Inter Oceanic Races and Languages" (Trübner, 1880)

beard and whiskers well furnished and always frizzled, or at least wavy, eyes perfectly straight and horizontal, nose not particularly prominent, but nearly always straight and never flattened at the root, cheek-bones scarcely if at all prominent, mouth of medium size and even small size, with moderately thick lips but no trace of prognathism, complexion mainly of a bister or brown colour, but varying from fair and even white to light brown and dark, though never so dark as that of the Aryans of India."

This description, given by a scientific observer, is the very antithesis of the Mongolian, and corresponds in all essentials to the ordinary Caucasian of Western Asia and Europe. Hence it is not surprising to find recent French writers freely applying to these peoples such epithets as "Caucasique," "Indo-Européen," "blanc," and so on. Bouillevaux calls the Chareys "white savages of Caucasian type." Thorel connects the northern tribes with "the Caucasian race, or more correctly with the Indo-European peoples." Dr. Harmand gives us a description of a beautiful Khang woman, dwelling particularly on her "aquiline nose, large eyes, thin lips, round shoulders," and other points of a European character. The Bolovens of Bassac he describes as of lighter complexion and taller than the surrounding Laos (Mongoloid) peoples, with sub-dolichocephalous head,

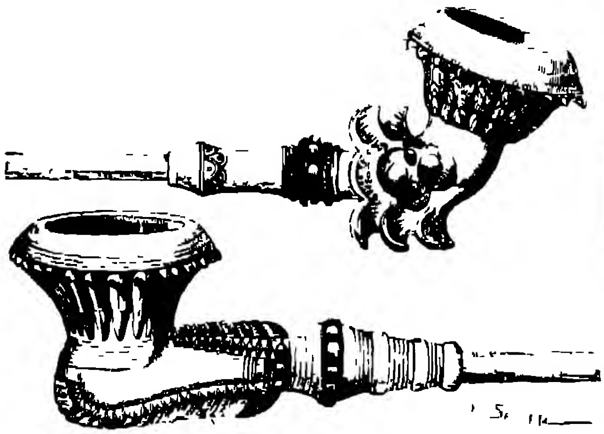


Fig. 11.—Stieng Pipes.

whereas that of the Laos is decidedly brachycephalic. Many Boloven women are remarkably beautiful in the European sense, with large straight eyes, regular features, and ruddy rather than yellow complexion. The colour of these wild tribes is often described as darker than that of their Siamese and Laos neighbours, but Dr. Harmand points out that this is due to the deep-rooted prejudice of the Laos, who habitually speak of them as even "black," though often fairer than the Laos themselves. The essential difference between the two races in this respect is precisely what we should expect, the Thai being more yellow, the Khâs, or Caucasian wild tribes, more red. This red or ruddy tinge was also noticed by Dr. A. Maurice amongst the Banhars, and the Piâks are even said to have wavy black hair with a russet hue, a trait never occurring in any pure branch of the Mongolian family.

These Caucasian tribes seem to be the true Aborigines of Indo-China, where they have been mostly supplanted, or driven to the impenetrable forests and highlands of the south-east by the intruding Mongol races, descending by the valleys of the great rivers from the Tibetan plateau. Still one branch, the Khmêrs, or Cambojans, were powerful and numerous enough to hold their ground in the lower Mekhong Valley, where, under Buddhistic influences, they established a flourishing empire and erected monuments 2000 years ago, whose stupendous ruins rival those of Java and India itself in archæological and artistic interest. Indeed it may be doubted whether there is anything in the whole world

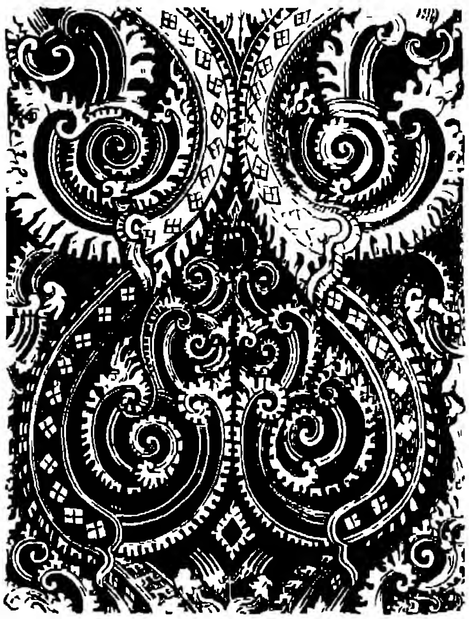

Fig. 12.—Ornamental Work on Stieng Quiver.

more wonderful in its way than the magnificent temple of Ongkor Vaht, on the northern shores of Lake Toulé-sap. It is noteworthy that the bas-reliefs and other figures on these monuments are of the same type as the present Cambojan race, with the same regular features, full beard,

Fig. 13.—Ornamental Work on Stieng Quiver.

and even their very dress, arms, and musical instruments. Traditions of this early civilisation still linger amongst the surrounding Khmêr tribes, many of whom, such as the Stîengs, Kings, and Chams, possess natural endow-

ments of a high order, cultivate their lands with great intelligence, are skilful workers in metals, and betray extreme taste in their decorative art. In the *Tour du Monde* for May 15, 1880, Dr. Harmand figures two native pipes and a quiver of a Stieng tribe, whose forms and arabesque designs are supremely beautiful (see Figs. 11, 12, and 13). "Their artistic instincts," this observer remarks, "are more developed and especially more original [than those of their Laos neighbours]. From them I have procured various objects betraying a refined taste, and woven fabrics with simple designs and well-harmonised colours." Amongst them there is prevalent a curious system of writing, at first sight somewhat suggestive of the Irish Ogham, but of a far more primitive character. It consists of a series of notches, varying in size and number, cut on both edges of a bamboo planchette, which is generally set up as a sort of public notice at the entrance to the villages. Thus a row made up of eight large, eleven medium-sized, and nine small notches was explained to mean "Our village contains eight men, eleven women, and nine children." It is evident that in a system of this sort as wide a scope must be left to the imagination as in the hypothetical primitive speech, in which broken utterances are largely supplemented by signs and gesture. A. H. KEANE

(*To be continued*)

GEOLOGY OF BOSNIA AND HERZEGOVINA[1]

AMID the conflict of political parties, the jealousies of rival powers, the rumours of renewed dispeace among the nations, and the smouldering embers of war that seem ready at any moment to burst forth into renewed conflagration, it is a relief to turn to a volume in which the Austrian Government has just shown to the world one of the first uses to which she has put her new acquisitions in the East. Nothing could have been more quietly and unostentatiously done, and nothing could show a more enlightened and humanising policy than the action which is modestly described in the volume before us. The story is briefly told by the Ritter von Hauer in an introductory note. It appears that immediately after the pacification of the occupied provinces of Bosnia and Herzegovina the Director of the Geological Institute at Vienna addressed to the Minister of Public Worship and Instruction (under whom the Geological Institute is placed) a letter in which he pointed out the desirability of expanding the pacific mission on which the country had entered in these provinces by organising a geological survey of them under the guidance of the Geological Institute. His representations were acceded to, and on March 9, 1879, he received instructions to commence a geological reconnaissance of the provinces with detailed investigation of such localities as might be found of sufficient importance. The task was to be undertaken conjointly by the Geological Institutes in Vienna and Buda-pest. The Director was requested as soon as possible to submit a plan of survey with proposals as to the number of geologists to be detailed and the individuals most competent for the exhaustive discharge of the duties required; and he was further instructed to put himself in direct relations with the Hungarian Geological Institute with a view to a proper sub-division of the work. Ritter von Hauer had no difficulty with one part of his instructions. Two of his staff, Dr. F. von Mojsisovics and Dr. E. Tietze, had already signified their wish to undertake the work, and Dr. Bittner expressed his desire to share in it. After some delay the Hungarian Institute made known its inability, from want of a sufficient staff, to take part in the intended survey. At last, on March 23, Director Von Hauer was able to announce to the Ministry that he was ready to begin operations. He proposed that as the work would naturally fall into two sections, (1) the preparation of a geological sketch-map of the whole occupied Provinces, and (2) a special detailed investigation of localities affording indications of salt, coal, or ores, it would be desirable to arrange the officers employed into two divisions. For the preparation of the map he suggested that four geologists should be employed, which, estimating the area to be surveyed at 1000 square German miles, would give 250 square miles to each surveyor. He recommended for this duty the three gentlemen above-named, and added the name of Prof. Hornes of Graz as the fourth, should the Hungarian Geological Institute have no other to propose. It was of course impossible that these officers, intrusted with the task of rapidly traversing the country and seizing on the salient features of its geological structure, should have time to halt anywhere long enough to make detailed investigations for useful minerals. This part of the duties however was one in which the services of the Hungarian Geological Institute might be especially useful, seeing that the distribution of ores in the Hungarian territory bore the closest analogy to that in Bosnia. The name of Herr F. Herlich of Klausenberg was accordingly suggested as one of the most competent persons to be intrusted with this part of the survey. It was further represented that the interesting and important coal and salt-spring region of Dolnj-Tuzla would be most fittingly explored by Herr Bergrath K. M. Paul, well known for his intimate acquaintance with the mineral tracts of Slavonia, Croatia, and the northern slopes of the Carpathian Mountains. Some further suggestions as to additional assistants were made. At last on April 7, 1879, the scheme of operations received the sanction of the Minister of Public Worship and Instruction.

By the beginning of May Herr Paul had broken ground in Bosnia. Before the end of the same month Herren von Mojsisovics, Tietze, and Bittner were likewise in the field, and undertook by themselves the whole burden of the map. In about three months the traverses for the construction of the map were completed, and the geological structure of a hitherto unexplored region of 1000 square German miles was added to our knowledge of the geology of Europe. One is at a loss whether most to admire the breadth of view which conceived and planned this first utilisation of an annexed territory, or the zeal and capacity which so rapidly carried out and completed the conception.

The *Jahrbuch der k. k. Geologischen Reichsanstalt* is one of the best-known and most useful geological journals in existence. The present number considerably exceeds the usual size of the periodical, since it is expanded by containing the reports of the geologists upon the recent survey of Bosnia-Herzegovina. Dr. von Mojsisovics takes West Bosnia and Turkish Croatia. In his report, after acknowledging assistance received in the country and enumerating the literature of the subject, in which the work of the veteran Ami Boué stands in the foremost place, the author proceeds to give a general outline of the topography and geology of the region examined by him. Most of his survey was done on horseback. He chose various traverses of the country, noting down by the way his observations upon the general map of Europe on a scale of $\frac{1}{300000}$, published by the Military Geographical Institute of Vienna. The first section of his report is devoted to geological topography, and includes some interesting information regarding what has been termed the "oriental fixed land"—an ancient island or nucleus round which, in the Balkan Peninsula, the Lias and more recent formations have been ranged. The second section treats of the geological formations in stratigraphical order, the more important being Triassic, Jurassic, Cretaceous, and Flysch, the last-named belonging partly to the Cretaceous

[1] *Jahrbuch der k. k. Geologischen Reichsanstalt*. Band xxx. Heft ii., containing "Grundlinien der Geologie von Bosnien Hercegovina," von Dr. E. v. Mojsisovics, Dr. E. Tietze und Dr. A. Bittner, mit Beiträgen von Dr. M. Neumayr und C. v. John. Vienna, 1880. The work is also published separately by Holder of Vienna, with a preface by Dr. v. Hauer.

and partly to the Eocene system. Among the younger formations the author devotes a couple of pages to sub-aerial deposits, including the results of the superficial weathering of rocks and the formation of "eluvial" accumulations. The third section describes the geological structure of different traverses of the country, and localities of geological interest, while a supplement contains observations on the mineral resources of the ground reported upon.

Dr. Tietze describes in a similar methodical way the geology of East Bosnia, while Dr. Bittner takes the Herzegovina and the south-east part of Bosnia. These reports are full of interest, especially in relation to the Cretaceous and Tertiary geology of the east of Europe. To some of the questions discussed in them we may return on another occasion. Though the geologists in their rapid marches had little time to collect specimens they nevertheless found opportunity to carry off some rocks and fossils which were found of sufficient importance to deserve special description. Herr C. v. John gives a report on some crystalline rocks of the Provinces, including granite, older plagioclase rocks, younger diabases, diorites, and similar rocks from the Flysch, gabbros, serpentines, eclogites, with trachytic and andesitic lavas. Dr. Neumayr describes a series of brackish-water shells from the Tertiary formations of the Provinces.

The Geological Institute of Vienna may be congratulated on the signal success of its well-planned and admirably-conducted enterprise. Rarely has so compendious a body of detailed information in geology been so rapidly accumulated and so promptly published. Ritter von Hauer's preface is dated March 1, 1880—that is within a year from the time when his proposal for the Survey was laid before the Austrian Government. These few months sufficed for the field-work, for the elaboration of the reports, and for the preparation of the map and engravings. The Reports form a volume of 333 closely-printed octavo pages. The map is issued in one sheet on the scale of $\frac{1}{576000}$, with twenty-one colours.

ARCH. GEIKIE

MICHEL CHASLES

Born November 15, 1793; *Died December* 18, 1880

"KNOW ye not that there is a prince and a great man fallen this day?" might well have been the thought of the President Becquerel when he announced to the Academy on the 20th ult. that Chasles was dead. To many the man who had surpassed in age Leibnitz by seventeen, Euler by eleven, Lagrange by ten, Laplace and Gauss by nine, and Newton by two years, was a "venerabile nomen," but yet a "nomen" only.

As far back as the present generation can remember Chasles has been a prince of geometers, and it has come upon many of us as a surprise to hear that he was still walking and working in our midst. A few years back a telegram was sent him from Boston conveying congratulations, and expressing the hope that the illustrious mathematician might see the close of the present century, in which event he would have surpassed the years of Pythagoras. Length of days is not always a boon, but Chasles's was a pleasant old age, and he died in harness; in such a case he might say with one of old, "nihil habeo quod incusem senectutem." "La vie de M. Chasles a été heureuse et simple; il a trouvé dans la Science, avec les plus grandes joies, une gloire qui sera immortelle, et dans la vive affection de ses amis, dans leur assiduité empressée aux réunions où il les conviait avec une grâce si aimable, dans leur respectueuse déférence en toute circonstance, la consolation de sa vieillesse."

Born at Epernon (Eure-et-Loir), he entered the École Polytechnique in 1812. At this early date he would communicate to students in the rival colleges the problems and exercises of the week, asking in return the questions proposed by their masters: "Dans cet échange organisé par le jeune lycéen, on peut croire aisément que le futur géomètre avait souvent la meilleure part." After taking his place in the defence of Paris in 1814 he passed out in engineering, but he re-entered the school in 1815. And this is the reason. Chasles was on the point of leaving for Chartres to show his uniform and to bid farewell to his mother before going to Metz, when he was waited on by the father of one of his comrades. "Mon fils," said the father, "est le premier des élèves qui n'ont pas obtenu de place; vous avez hésité, je le sais, à accepter l'épaulette; votre refus aurait assuré à votre camarade une carrière qui lui plaît et pour laquelle j'ai fait les derniers sacrifices; il m'est impossible de les continuer pour lui en préparer une autre." Chasles made no reply: he went to Chartres; on his arrival his choice was made, and he told his mother he would stay with her. The army lost him as an officer, the world gained him as a geometer. On finally leaving the establishment, in spite of the high position he held amongst his companions, he voluntarily renounced public employment (Larousse states however, "Fut agent de change et plus tard aux affaires pour les sciences") and went to Chartres, where he spent some ten years. He was working quietly however. "Toujours passionné pour la géométrie, il résolvait de beaux problèmes, comme au collège, trouvait chaque jour d'élégants théorèmes, inventait des méthodes générales et fécondes, sans attirer l'attention des maîtres de la science et sans y prétendre. 'Que de talent perdu!' disaient les plus bien-veillants, sans songer même à traiter d'égal ce jeune homme obstiné à approfondir les théories élémentaires et qui bientôt peut-être devait, par elles, s'élever bien au-dessus d'eux." Elected a Corresponding Member of the Academy in 1839 ("decorated" the same year), he was made "Professeur de Machines et de Géodésie" at the École Polytechnique, in succession to Savary in 1841. This chair he occupied for ten years, when, in consequence of some alterations ("profondes et très regrettables"[1]), he sent in his resignation, and ever afterwards did all in his power to combat these, as he thought, dangerous reforms. His affection however continued unabated. "C'est ainsi qu'il acceptait avec tout d'empressement la présidence du Comité de la Société amicale des Anciens Élèves; c'est ainsi qu'il entrait au conseil de perfectionnement, et que, tout récemment encore, malgré son grand âge, il acceptait le renouvellement de son mandat, avec le désir, disait-il, de continuer jusqu'à son dernier souffle à entretenir ce foyer de travail, d'honneur et de dévouement au pays." With the ardour which so distinguished him, M. Chasles had undertaken to write a history of the school; an extract from this history he recently published: "Exposé historique concernant le Cours de Machines, dans l'Enseignement de l'École Polytechnique" (see notice in NATURE, vol. xxiii. p. 75). M. Laussedat informs us that the veteran's wish is in great part attained, and that it was with great pleasure Chasles learned before his death that the *Journal de l'École Polytechnique* is to be revived, and that the revision of the "programmes de l'enseignement" was decided upon. In France the professorial chairs are *special*.[2] Poinsot was, for some years, desirous that a chair should be appointed for the Modern Geometry, and in 1846 this chair was created by the Faculté des Sciences, and Chasles was elected to be the first occupant. In 1851 he was elected a Member of the Academy, and in the same year, as above stated, gave up his appointment at the Polytechnic. In 1854 he became Foreign Member of our Royal Society, in 1865 he was awarded the Copley medal, and in April, 1867, he was elected the first (and for some time the only) Foreign Member of the London

[1] Note, p. 583, to the admirable "Discours d'Inauguration de Cours de Géométrie Supérieure de la Faculté des Sciences de Paris" (December 22, 1846) which follows the second edition of the "Traité de Géométrie Supérieure" (1880).

Mathematical Society. His honours of membership were numerous, and are printed on the title-pages of his works. The Pascal-Newton controversy has already been alluded to in these pages, and we willingly leave it here untouched.

"M. Chasles a poursuivi son œuvre sans interruption depuis sa sortie du Lycée jusqu'à l'âge de quatre-vingt-sept ans. Soixante-huit années séparent la première note de l'élève Chasles, insérée dans la *Correspondance sur l'École Polytechnique*, du dernier mémoire présenté à l'Académie des Sciences. Tous les géomètres, sans distinction de nationalité ni d'école, se sont inclinés devant ce vénérable vieillard; tous ont admiré sa puissance d'invention, sa fécondité, que l'âge semblait rajeunir, son ardeur, et son zèle, continués jusqu'aux derniers jours."

A mere recital of the titles of M. Chasles' numerous papers would fill several columns. In the "Catalogue of Scientific Papers" will be found the titles of 177, and from the slight examination we have been able to make we have little doubt that the number published since 1873 would bring the total to nearly 240. The subjects range over curves and surfaces of the second and of any degree, geometry, mechanics (and attractions), history, and astronomy. Amongst his earliest papers are those which were translated by the present Bishop of Limerick in 1841, under the title "Two Geometrical Memoirs on the General Properties of Cones of the Second Degree, and on the Spherical Conics." "These possess strong claims on the attention of mathematicians, whether they are considered merely as exercises of pure geometry, exhibiting its elegance and power in a remarkable degree, or as a rich and early contribution to the theory of spherical curves."

Chasles himself remarks in his *Rapport*[1] (which perhaps furnishes the best key to his writings), "On peut s'étonner que, jusque vers la fin du premier tiers de ce siècle, on n'ait eu l'idée d'étudier ni les propriétés des cônes du second ordre qui servent à engendrer les coniques, ni celles des courbes qui tiennent sur la sphère le rang des coniques sur le plan" (p. 75).

In reply to the question, "On demande un examen philosophique des différentes méthodes employées dans la géométrie récente et particulièrement de la méthode des polaires reciproques," was written, "Mémoire de Géométrie sur deux Principes généraux de la Science, la Dualité, et l'Homographie" (January, 1830, to the Académie Royale of Brussels), preceded by some historical researches. This work subsequently took the form of the famous "Aperçu historique sur l'Origine et le Developpement des Méthodes en Géométrie . . . suivi d'un Mémoire . . . sur deux Principes généraux . . . et l'Homographie." This work appeared in 1837, and having become exceedingly scarce, was reprinted verbatim in 1875, with the addition of a short preface giving a brief historical account of the book. In the *Rapport* (p. 80) we are told "c'est cette troisième partie" (the memoir on Duality and Homography) "qui à donné lieu à la composition de l'ouvrage. La théorie des figures homologiques et celle des polaires reciproques qui sont la base des beaux travaux de l'illustre Général Poncelet donnèrent une heureuse impulsion aux recherches de pure géométrie." These two methods were susceptible, he says, of generalisation, and the progress of the science demanded it. The *Aperçu*, which has been translated into German (except the third part) by Sohncke, is a perfect mine of geometrical facts, and is to the present day a high authority on the subject of which it treats. In some places too great reliance on Montucla (see Dr. Allman on "Greek Geometry from Thales to Euclid," p. 171, cf. also p. 202), and in others non-acquaintance with German ("nous éprouvons un vif regret de ne pouvoir citer ici leurs ouvrages, qui nous sont inconnues, par suite de notre ignorance de la langue dans laquelle ils sont écrits," p. 215) may slightly detract from its merits, but after all deductions it exhibits a vast amount of research and originality, and well merits the title of *ouvrage classique*.[1]

The appointment to the Chair of Modern Geometry necessitated a course (or courses) of lectures, and in 1852 these were embodied in the "Traité de Géométrie supérieure," "an elaborate and masterly treatise," which of late years has been rarely attainable, and only at a very high price. M. Chasles, hardly two months before his death, had the satisfaction of seeing a second edition, accompanying which is (pp. 547-585) the excellent "Discours d'Inauguration" (referred to above). The three fundamental principles of this work are "Anharmonic Ratio of Four Points," "Homographic Divisions," and "Involution" (*Rapport*, p. 220).

In 1865 appeared the first volume of the "Traité des Sections coniques, faisant suite au Traité de Géométrie supérieure." As its title indicates, constant application is made in it of the principles of pure geometry unfolded in the earlier work. It thus differs considerably not only from analytical treatises, but from geometrical treatises also. "Ces trois théories primordiales s'appliquent avec une extrême facilité à toutes les recherches concernant les sections coniques" (*Rapport*, pp. 266-9).

Mathematicians have long looked for a second volume, materials for which have appeared in the *Comptes rendus*. In the *Rapport* (pp. 257-266) will be found an account of the method of *geometrical substitution* and a definition of the *elements* (or *characteristics*) of a system of conics (*Comptes rendus*, 1864-7). Numerous applications are made of this remarkable theory (for further accounts the English student may refer to Dr. Salmon's "Higher Plane Curves," pp. 360, &c., and "Conics," p. 368; see also later papers in the *Comptes rendus*, vol. lxxviii.[2] p. 577, &c., vol. lxxxv. p. 362, pp. 460-6).

We must now go back to the year 1863, when Chasles published his "Les trois Livres de Porismes d'Euclide, rétablis pour la première Fois, d'après la Notice et les Lemmes de Pappus, et conformément au Sentiment de R. Simson, sur la Forme des Enoncés de ces Propositions." In 1838 he had contributed a paper, "Sur la Doctrine des Porismes d'Euclide," to Quetelet's *Corresp. Math.* x. (pp. 1-23). We must content ourselves with referring to the *Rapport*, pp. 155, 233-42; the *Aperçu*, pp. 39, &c. (He cites Montucla as to the profoundness of the Porisms, gives high praise to Simson, and shows that there is in Pappus's Lemmas what is in effect the projective property of the anharmonic ratio of four points). The publication of this work led to a short controversy with M. P. Breton ("Question des Porismes—notices sur les débats de priorité auxquels a donné lieu l'ouvrage de M. Chasles sur les porismes d'Euclide," Paris, 1865; and a second part, Paris, 1866). M. Chasles comments on these in the *Rapport* (cf. reff. above).

We turn now for a moment to the subject of attraction. "La question de l'attraction presenta-t-elle à l'auteur sous plusieurs points de vue, qui donnèrent lieu à divers mémoires et s'étendirent même au problème général de l'attraction d'un corps de forme quelconque" (*Rapport*, p. 101); on p. 103 he gives a history of Maclaurin's theorem (of which Todhunter—"History of the Theories of Attraction," &c., vol. i. 260, writes: "Chasles is correct"); on p. 105 we read: "Mais il restait toujours à désirer une démonstration directe et rigoureuse du théorème de Maclaurin," and he cites an extract from Poinsot's report on his paper (*Mémoires* par divers Savants, t. ix. 1846). "Ce mémoire remarquable nous offre un nouvel exemple de l'élégance et de la clarté que la géométrie peut répandre sur les questions les plus

[1] Pp. 72-156, 220-280, contain an account of the author's own contributions to geometry.

[1] De Morgan says, "A work of great importance in the historical point of view."

[2] "Considérations sur le caractère propre du principe de correspondance." "S'applique avec une très grande facilité, à une infinité de questions."

obscures et les plus difficiles" (*Comptes rendus*, t. vi 1838, pp. 808–812)

Thus, the first *synthetic* solution (of General Sabine's address on presenting the Copley Medal) was published, if we mistake not, in 1837 M Bertrand, in his *éloge* of Lamé (January 28, 1878, *Mémoires* de l'Académie des Sciences), says "M. Chasles obtenait, en la transportant à la théorie si souvent étudiée de l'attraction des ellipsoides, des démonstrations et des résultats admirés comme un modèle d'élégance et de généralité."

We have no space left, having perhaps already dwelt too much in detail upon the complete works, to give an account of the numerous papers we referred to above This is the less necessary as the results of many are already incorporated in the larger works We must however just mention the important mechanical principle founded upon the proposition "quand deux polygones égaux sont placés d'une manière quelconque dans un plan, il existe toujours un point du plane qui est également distant de deux sommets homologues quelconques des deux polygones, le point est semblablement placé par rapport aux deux polygones"

The applications of this, under Poncelet's form of enunciation, are fully treated of by Richard in his "Note sur un nouveau principe de cinématique sur son emploi et sur la Théorème de M Chasles" (Paris, 1856)

In the closing lines of the *Rapport* M Chasles indignantly condemns the modern system which has for its supreme and immediate object *des applications pratiques*; and which is "caracterisée suffisamment par l'idée fatale de *bifurcation*" These remarks we pass over, but gladly draw attention to a wish which he strongly expresses, viz that a defect should be remedied by the creation of two chairs, one for "Géométrie infinitésimale et analytique," and the other for "Analyse transcendante" If these chairs do not now exist, it would be a fitting compliment to his memory to establish one or both One other wish we have which we repeat, and that is, following the fashion of the time, that a collected edition of his papers be issued, for at present they are scattered over a very wide area

In this notice we are indebted to the funeral speeches pronounced over M Chasles's grave (*Comptes rendus*, xci No. xxv., December 20, 1880) which, and M. Chasles's own remarks, we have freely cited in their original language, thereby securing conciseness of expression.

We must however linger no longer by the grave, but turn to the "living present," after repeating M. Dumas's last words, "Adieu, Chasles, adieu!" R TUCKER

PROF. HUXLEY ON EVOLUTION[1]

II

IF all the Mammalia are the results of a process of evolution analogous to that which has taken place in the case of the Equidæ, and if they exhibit different degrees of that process, then a natural classification will arrange them, in the first instance, according to the place which they occupy in the scale of evolution of the mammalian type, or the particular rung of the "scala mammalium" on which they stand. The determination of the position thus occupied by any group may, I think, be effected by the deductive application of the laws of evolution That is to say, those groups which approach the non-mammalian Vertebrata most closely, present least inequality of development, least suppression, and least coalescence of the fundamental parts of the type, must belong to earlier stages of evolution, while those which exhibit the contrary characters must appertain to later stages.

Judged from this point of view, there can be no doubt that the Monotremes embody that type of structure which constitutes the earliest stage of mammalian organisation —

1. The mammary glands are devoid of teats, and thus the essential feature of the mammal could hardly be presented under a simpler form

2 There is a complete and deep cloaca, as in Vertebrata lower in the scale.

3 The openings of the ureters are *hypocystic*—that is to say, they open, not into the bladder of these animals, but behind it, into the dorsal wall of the genito-urinary passage. As this answers to the neck of the allantois, the ureters of the Monotremes retain their primitive embryonic position.

4. There is no vagina apart from the genito-urinary passage, and the oviducts are not differentiated into distinct uterine and Fallopian regions

5 The penis and the clitoris are attached to the ventral wall of the cloaca

6. The epiphyses of the vertebræ are but slightly, or not at all developed[1]

7 The malleus is relatively very large, and the "processus gracilis," which is singularly long and strong, passes between the tympanic and the periotic bones to the pterygoid, with which it is firmly united Thus the palato-pterygoid apparatus is directly connected by a "suspensorium" with the periotic, as in the Amphibia and Sauropsida. As in these, the representative of the incus is extremely small and that of the stapes columelliform

8 The coracoid is complete, distinct, and articulates with the sternum

9 The hip-girdle is provided with large epipubes, and the iliac axis is inclined at a large angle to the sacral axis

10 The corpus callosum is very small.

11 There appears to be no allantoic placenta, though, from the obvious remains of the ductus arteriosus and of the hypogastric arteries, there can be little doubt that the fœtus has a large respiratory allantois It is quite possible that, with a large umbilical sac, there may be an imperfect "umbilical" placentation

But, while the *Ornithorhynchus* and the *Echidna* are thus the representatives of the lowest stage of the evolution of the Mammalia, I conceive it to be equally unquestionable that, as Haeckel has already suggested, they are greatly modified forms of that stage—*Echidna*, on the whole, representing a greater, and *Ornithorhynchus* a less, departure from the general type The absence of true teeth in both genera is an obvious sign of extreme modification. The long tongue, extraordinary external auditory passages, and relatively large convoluted brain of *Echidna*, and the cheek-pouches and horny mouth plates of *Ornithorhynchus*, are other indications of the same kind.

Hence, the primary mammals which were less modified, and the existence of which is necessarily postulated in the conception of the evolution of the group, cannot, without risk of confusion, be called Monotremata or Ornithodelphia, since in all probability they were as widely different from *Ornithorhynchus* and *Echidna* as the Insectivora are from the Edentata, or the Ungulata from *Rhytina* It will therefore be convenient to have a distinct name—*Prototheria*—for the group which includes these, at present, hypothetical embodiments of that lowest stage of the mammalian type, of which the existing Monotremes are the only known representatives.

A similar reasoning applies to the Marsupialia. In their essential and fundamental characters they occupy an

[1] Continued from p 204 By the courtesy of the Secretary of the Zoological Society we are able to give the remainder of the paper "On the Application of the Laws of Evolution to the Arrangement of the Vertebrata, and more particularly of the Mammalia," by Prof T. H Huxley, F.R S

[1] Dr Albrecht ("Die Epiphysen und die Amphiomphalie der Säugethierwirbel-körper" *Zoologischer Anzeiger*, 1879, No 18), while admitting that *Echidna* has no epiphyses, describes epiphyses of an incomplete character between the posterior twelve caudal vertebræ of *Ornithorhynchus* So far as I am aware, the memoir of which Dr Albrecht has given a preliminary notice, has not yet been published I content myself therefore with remarking that my own recent observations are in harmony with Dr Albrecht's statement

intermediate position between the Prototheria and the higher mammals

1. The mammary glands are provided with teats

2. The cloaca is so greatly reduced that it is often said to have disappeared

3. The openings of the ureters are *entocystic*—that is to say, the ureters open into what is called the "base" of the bladder in front of the narrowed "neck" by which it passes into the tubular "urethra." This means, I conceive, that, morphologically, the bladder of the Marsupial represents the bladder of the Monotreme + the anterior part of the genito-urinary passage, the so-called "trigonum," if not more, of the bladder of the Marsupial, being the homologue of that anterior segment of the genito-urinary passage of the Monotreme

4. There is a distinct and long vagina, quite separated from the cystic urethra, in the female, and the oviducts are differentiated into uterine and Fallopian portions.

5 The penis is large, and the corpora cavernosa are connected by fibrous tissue and muscles with the pelvis The spongy body has a large bifurcated bulb, and Cowper's glands are very largely developed

6. The vertebræ have distinct epiphyses

7 The malleus is small, and its connections are similar to those which it possesses in the higher mammals The incus is relatively larger, and the stapes more or less stirrup-shaped.

8 The coracoid is short, does not articulate with the sternum, and becomes ankylosed with the scapula

9. The hip-girdle is provided with epipubes, usually of large size and well ossified, and the iliac axis is inclined at a small angle to the sacral axis

10. The corpus callosum is small

11 In the few forms of which the fœtus is known there is no allantoic placenta, while the umbilical sac is so large that the possibility of the existence of a transitory umbilical placentation must be taken into account

It will be observed that in the characters 1, 2, 3, 4, 5, 6, 7, 8, and the latter part of the 9th, the Marsupials agree with the higher mammals, while in the former part of the 9th, the 10th, and the 11th, they present Prototherian characters So far, therefore, they constitute an intermediate type between that of the Prototheria and that of the higher mammals, which may be termed that of the *Metatheria*. And if there were any known animals which combined these characters, with a complete double dentition, unmodified pentadactyle manus and pes, and normal uterogestation, they would furnish us the exact transition between the Prototheria and the higher mammals, which must have existed if the law of evolution is trustworthy.

No known Marsupial, however, possesses these additional characters None has more than a single successional tooth on each side of each jaw, and, as Prof. Flower (to whom we owe the highly important demonstration of this fact) has pointed out, the question arises whether we have here a primary dentition with only one secondary tooth, or a secondary dentition with only one tooth of the primary set left I have no doubt that the answer given to this question by Prof Flower is correct, and that it is the milk-dentition of which only a vestige is left in the Marsupialia. Among existing Rodents, in fact, all conditions of the milk-dentition exist, from a number equal to that of the permanent incisors and premolars (as in the Rabbit[1]) to none at all

The same thing is observed in the Insectivora, where the Hedgehog, and probably *Centetes*, have a full set of milk-teeth, while none have yet been found in the Shrews. In these cases, it is obvious that the milk-dentition has gradually been suppressed in the more modified forms; and I think that there can be no reasonable doubt that the existing Marsupials have undergone a like suppression of the deciduous teeth, in the course of their derivation from ancestors which possessed a full set.

Again, no existing Marsupial possesses an unmodified pentadactyle pes. If the hallux is present, it presents an extensive movement in adduction and abduction, in fact, the pes is prehensile This is the case in the *Phascolomyidæ*, *Phalangistidæ*, *Phascolarctidæ*, and *Didelphidæ* The *Dasyuridæ* present the same type of pes, with the hallux reduced or suppressed Hence, considering the relations of the *Macropodidæ* and the *Peramelidæ* with the Phalangers, it seems likely that the hind foot in these groups is also a reduced prehensile pes; in which case this special modification of the foot would characterise the whole of the existing *Marsupialia*

Thirdly, the most marked peculiarities of the reproductive organs and processes in the Marsupial are in no wise transitional, but are singularly specialised characters The suspension of the scrotum in front of the root of the penis is unlike any arrangement in the higher mammals, and the development of the bulb and of Cowper's glands is in excess of anything observable in them In the female, the cystic urethra is as completely separated from the vagina as it is in the higher mammals, while the doubling of the vagina must, in my opinion, also be considered as a special peculiarity which leads from, rather than towards, the higher mammals In a Monotreme, in fact, the anterior end of the genito-urinary passage exhibits two very short dilatations or cornua, one on each side. In the middle line, a little distance behind these, the ureters open on a prominent ridge-like papilla The opening of the bladder lies in front of and below the genital cornua Now, if we compare this arrangement with that which obtains in the lower forms of the higher Mammalia, we find that the ureteric papillæ have separated laterally and moved forwards, in such a manner as to occupy the base of the bladder, and the genital cornua come to lie behind and somewhat dorsad of them At the same time a longitudinal separation has taken place between what may be called the "ureteric" region of the genito-urinary passage and the "genital" region The first is taken into the bladder and becomes connected by a longer or shorter "cystic urethra" with the latter, which is converted into the longer or shorter vagina In the Marsupial the same general modification has taken place, but the "genital cornua" become immensely elongated, and give rise to the so-called "double" vagina

Lastly, the marsupium, where it exists, is a no less special feature of the Marsupialia, and, like the peculiarities of the female genital organs, appears to be related with the abnormally early birth of the fœtus Among the higher Mammalia, it is well known that the fœtus is born in a relatively much earlier state in some cases than in others, even among closely allied species. Thus Rabbits are born hairless and blind, while Hares are born hairy and with their eyes open I think it probable, from the character of the pes, that the primitive forms, whence the existing Marsupialia have been derived, were arboreal animals, and it is not difficult, I conceive, to see that with such habits it may have been highly advantageous to an animal to get rid of its young from the interior of its body at as early a period of development as possible, and to supply it with nourishment during the later periods through the lacteal glands, rather than through an imperfect form of placenta.

However this may be, the characters of the existing Marsupialia leave no doubt on my mind that they are greatly modified members of the metatherial type, and I suspect that most, if not all, of the Australian forms are of comparatively late origin. I think it probable that the

[1] The deciduous molars and the posterior deciduous upper incisors of the Rabbit have been long known But I have recently found that unborn Rabbits possess, in addition, two anterior upper and two lower deciduous incisors Both are simple conical teeth, the sacs of which are merely embedded in the gum. The upper is not more than one-hundredth of an inch long, the lower rather larger It would be interesting to examine fœtal Guinea pigs in relation to this point, at present they are known to possess only the hindmost deciduous molars, so far agreeing with the Marsupials.

great majority of the Metatheria, of which I doubt not a great multitude will shortly be discovered in Mesozoic formations, differed widely from our existing Marsupials, not only lacking the pouch, as do some existing "Marsupialia," but possessing undivided vaginæ, and probably bringing forth their young, not earlier than existing Carnivores and Rodents do, the nutrition of the fœtus during prolonged gestation being provided for, in all probability, by an umbilical placental apparatus, and its respiration by a non-placental allantois

In the remaining group of the Mammalia, hitherto spoken of as the "higher Mammalia"—

1. The mammary glands are provided with teats[1]

2 The cloaca has usually disappeared Sometimes, however (Beavers, Sloths), a shallow cloaca is present, especially in the female.

3 The openings of the ureters are always entocystic, but their position varies greatly, from close to the neck (e.g *Sorex*) to the anterior end of the bladder (e g *Hyrax*).

4. There is a distinct vagina, which is almost always undivided. The oviducts are differentiated into uterine and Fallopian portions

5 The penis is usually large, the bulb single or partially divided, and the corpora cavernosa almost always directly attached to the ischia

6 The vertebræ have epiphyses

7. The malleus is usually small, the incus relatively large, the stapes stirrup shaped

8 The coracoid is almost always much reduced, and it is ankylosed with the scapula

9 The iliac axis makes a small angle with the sacral axis, and there is no epipubis, or only a fibrous vestige of it

10. The corpus callosum and the anterior commissure vary widely In such forms as *Erinaceus* and *Dasypus* they are almost Monotreme-like

11 The fœtus is connected with the uterus of the mother by an allantoic placenta The umbilical sac varies in size, and in some lower forms (e g *Lepus*) it is, at first, highly vascular, and perhaps plays a quasi-placental part during the early stages of development

It is obvious that, in all these respects, we have the mammalian type in a higher stage of evolution than that presented by the Prototheria and the Metatheria. Hence we may term forms which have reached this stage the *Eutheria*

It is a fact, curiously in accordance with what might be expected on evolutionary principles, that while the existing members of the Prototheria and the Metatheria are all extremely modified, there are certain forms of living Eutheria which depart but little from the general type For example, if *Gymnura* possessed a diffuse placentation, it would be an excellent representative of an undifferentiated Eutherian Many years ago, in my lectures at the Royal College of Surgeons, I particularly insisted on the central position of the Insectivora among the higher Mammalia, and further study of this order and of the Rodentia has only strengthened my conviction, that any one who is acquainted with the range of variation of structure in these groups, possesses the key to every peculiarity which is met with in the Primates, the Carnivora, and the Ungulata Given the common plan of the Insectivora and of the Rodentia, and granting that the modifications of the structure of the limbs, of the brain, and of the alimentary and reproductive viscera, which occur among them, may exist and accumulate elsewhere, and the derivation of all the *Eutheria* from animals which, except for their simpler placentation, would be Insectivores, is a simple deduction from the law of evolution.

There is no known Monotreme which is not vastly more different from the Prototherian type, and no Marsupial which has not far more widely departed from the Metatherian type, than *Gymnura*, or, indeed, *Erinaceus*, have from the Eutherian type

The broadest physiological distinction between the Prototheria, the Metatheria, and the Eutheria respectively lies in the differences which the arrangements for prolonging the period of intra uterine and extra-uterine nutrition by the parent present in each The possibility of a higher differentiation of the species is apparently closely connected with the length of this period Similarly, the broadest morphological distinction which can be drawn among the *Eutheria* lies in their placentation. All forms of deciduate placentation commence by being non-deciduate, and the intimate connection of the fœtal with the maternal structures is subsequent to their loose union Hence *Eutheria*, with deciduate placentæ, are in a higher stage of evolution than those with non-deciduate placentæ

In discussing the relations of the various existing groups of the higher Mammalia with one another, it would be a mistake to attempt to trace any direct genetic connection between them Each, as the case of the Equidæ suggests, has probably had a peculiar line of ancestry, and, in these lines, Eutherian forms with deciduate placentation constitute the latest term, Eutherian forms with non-deciduate placentation the next latest, Metatherian forms the next, Prototherian forms the earliest among those animals which, according to existing definition, would be regarded as Mammals

The accompanying Table (p 230) presents, at a glance, the arrangement of the Mammalia in accordance with the views which I have endeavoured to express The sign O marks the places on the scheme which are occupied by known Mammals, while × indicates the groups of which nothing is known, but the former existence of which is deducible from the law of evolution

I venture to express a confident expectation that investigation into the Mammalian fauna of the Mesozoic epoch will sooner or later fill up these blanks But if deduction from the law of evolution is to be justified thus far, it may be trusted much farther If we may confidently expect that *Eohippus* had a pentadactyle claviculate ancestor, then we may expect, with no less confidence, that the *Prototheria* proceeded from ancestors which were not mammals, in so far as they had no mammary glands, and in so far as the mandible was articulated with a quadrate bone or cartilage, of which the malleus of the true mammal is the reduced representative Probably also the corpus callosum had not appeared as a distinct structure

Our existing classifications have no place for this "sub-mammalian" stage of evolution (already indicated by Haeckel under the name of *Promammalia*) It would be separated from the Sauropsida by its two condyles, and by the retention of the left as the principal aortic arch; while it would probably be no less differentiated from the Amphibia by the presence of an amnion and the absence of branchiæ at any period of life I propose to term the representatives of this stage *Hypotheria*, and I do not doubt that, when we have a fuller knowledge of the terrestrial Vertebrata of the later palæozoic epochs, forms belonging to this stage will be found among them. Now, if we take away from the Hypotheria the amnion and the corpus callosum, and add the functional branchiæ—the existence of which in the ancestors of the Mammalia is as clearly indicated by their visceral arches and clefts, as the existence of complete clavicles in the ancestral Canidæ is indicated by their vestiges in the dog—the Hypotheria, thus reduced, at once take their place among the Amphibia. For the presence of branchiæ implies that of an incompletely divided ventricle and of numerous aortic arches, such as exist in the mammalian embryo, but are more or less completely suppressed in the course of its development

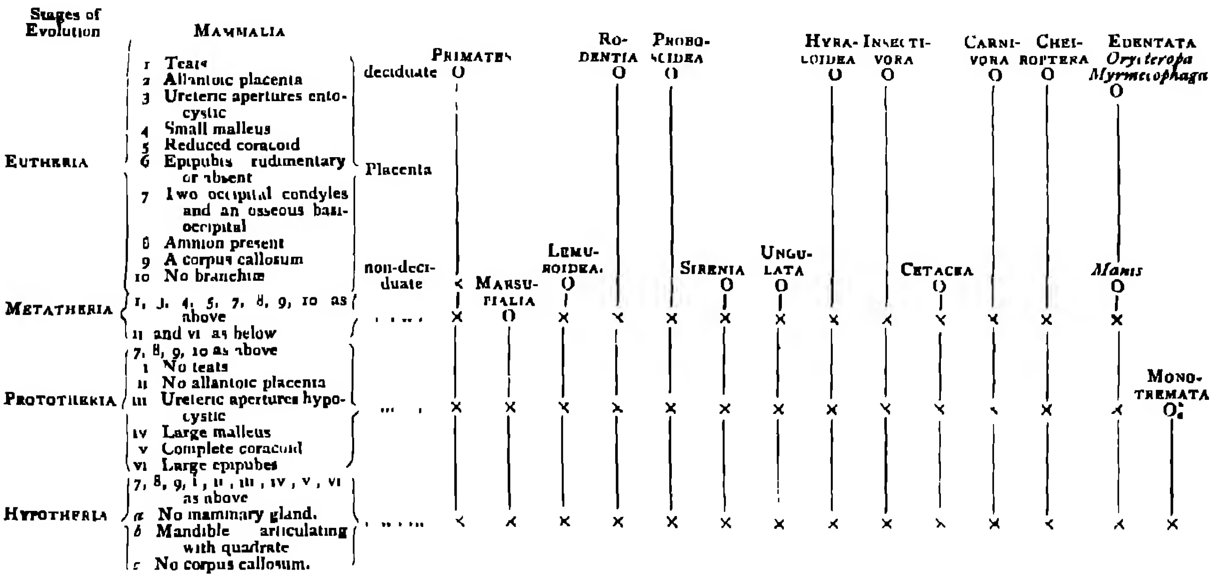
[1] The only exception known to me is the Cape Mole (*Chrysochloris*), which, according to Peters, has none

Thus I regard the Amphibian type as the representative of the next lower stage of vertebrate evolution; and it is extremely interesting to observe that even the existing Amphibia present us with almost every degree of modification of the type, from such forms as the oviparous, branchiate, small-lunged *Siredon* and *Menobranchus*, which stand in the same relation to it as *Gymnura* to the Eutheria, to the exclusively air-breathing Salamanders and Frogs, in which the period of intraovular development, either within the uterus itself or in special receptacles, may be as much prolonged as it is in the Mammalia.

A careful study, on full materials, of the development of the young of such forms as *Hylodes* will probably throw great light on the nature of the changes which ended in the suppression of the branchiæ, and the development of the amnion and of the extra-abdominal part of the allantois in the fœtus of the higher Vertebrata.

The recent researches of Boas[1] on the structure of the heart and the origin of the pulmonary arteries of *Ceratodus* fell into my hands when I happened to be working afresh at the subject, and had arrived, so far as the heart is concerned, at results which are entirely confirmatory of his. This wonderful creature seems contrived for the illustration of the doctrine of evolution. Equally good arguments might be adduced for the assertion that it is an amphibian or a fish, or both, or neither—the reason of this being that, as it appears to me, *Ceratodus* is an extraordinarily little modified representative of that particular stage of vertebrate evolution of which both the typical Fishes and the typical Amphibia are special modifications. I think it will be convenient to have a name for the representatives of this stage, and I propose that of *Herpetichthyes*.

If we were to take away from *Ceratodus* the membrane-bones of the heart and the pneumatocœle, and slightly simplify the structure of the heart, the result would be an animal which would undoubtedly be classed among the *Chimeroidei*, and if, in such a Chimæroid, the lamellar septa of the branchiæ were not reduced, as they are in the *Chimeroidei*, while the opercular fold remained undeveloped, the product would be a little modified representative of the Selachian group, to which, among actually known forms, *Heptanchus* and *Cestracion* present the nearest approximations. Vertebrated animals in this stage of evolution may be termed *Chondrichthyes*.



Suppose the limbs and the genital ducts of the *Chondrichthyes*-stage to be undeveloped, and let the two nasal sacs be represented by a partially divided sac with a single external aperture, the result will be a still lower grade of vertebrate life, which may be termed *Myzichthyes*, represented only by the greatly modified Lampreys and Hags of the existing fauna.

Finally, let the head retain its primitive segmentation, and the heart its primitive character of a contractile tube, and we reach, in the *Hypichthyes*, a stage of simplification of the vertebrate type, from which it would be difficult to remove any essential feature without reaching a point at which it is questionable whether an animal should be called "vertebrate." This stage is at present represented only by a singularly modified form, the living *Amphioxus*.

Thus, in the order of evolution all the Vertebrata hitherto considered may be arranged in nine stages:—1, that of the *Hypichthyes*; 2, that of the *Myzichthyes*, 3, that of the *Chondrichthyes*; 4, that of the *Herpetichthyes*; 5, that of the *Amphibia*; 6, that of the *Hypotheria*, 7, that of the *Prototheria*; 8, that of the *Metatheria*, and, 9, that of the *Eutheria*. All these stages, except that of the *Hypotheria*, are represented by existing groups of vertebrated animals, which, in most cases, are composed of greatly modified forms of the type to which they belong, only the Amphibia and the Eutheria exhibiting near approximations to the unmodified type in some of their existing members.

It will be observed that I have omitted to mention the Ganoid and the Teleostean Fishes and the Sauropsida. I have done so because they appear to me to lie off the main line of evolution—to represent, as it were, side tracks starting from certain points of that line. The Ganoidei and the Teleostei I conceive to stand in this relation to the stage of the Herpetichthyes, and the Sauropsida to the stage of the Amphibia.

There is nothing, so far as I can see, in the organization of the Ganoid and Teleostean fishes which is not readily explicable by the application of the law of evolution to the Herpetichthyes. They may be interpreted as effects of the excessive development, reduction, or coalescence of the parts of a Herpetichthyan.[1]

[1] "Ueber Herz und Arterienbogen bei *Ceratodus* und *Protopterus*," *Morph. Jahrbuch*, 1880.

[1] That the heart of *Butirinus* affords a complete transition between the characteristically Ganoid and characteristically Teleostean heart, has recently been proved by Boas (*Morphol. Jahrbuch*, 1880). Thus the last remnant of the supposed hiatus between the Ganoids and the Teleostean vanishes.

Similarly, the suppression of the branchiæ, the development of an amnion, and of a respiratory extra-abdominal allantois, and that enlargment of the basioccipital relatively to the exoccipitals which gives rise to a single skull-condyle, is all the change required to convert an Urodele amphibian into a Lizard It is needless to recapitulate the evidence of the transition from the Reptilian to the Bird type, which the study of extinct animal-remains has brought to light

The scheme of arrangement of the Vertebrata which naturally flows from the considerations now brought forward will stand thus —

Stages of Evolution	Representative Groups		
9 *Eutheria*	*Monodelphia* O		
8. *Metatheria*	*Marsupialia* O		
7 *Prototheria*	*Monotremata* O		
6. *Hypotheria*	×	*Sauropsida* {*Aves*, *Reptilia*} O	
5 *Amphibia*	*Amphibia* O	×	
4 *Herpetichthyes*	*Dipnoi* O	×	*Osteichthyes* {*Ganoidei*, *Teleostei*} O
3 *Chondrichthyes*	*Chimaeroidei* O		×
	Selachii O		×
2 *Myzichthyes*	*Marsipobranchii* O	×	×
1 *Hypichthyes*	*Pharyngobranchii* O	×	×

It appears to me that everything which is at present known respecting the Vertebrata of past epochs agrees with the assumption that the law which expresses the process of ancestral evolution of the higher Mammalia is of general application to all the Vertebrata If this is admitted, I think it necessarily follows that the Vertebrata must have passed successively through the stages here indicated, and that the progress of discovery, while it will obliterate the lines of demarcation between these stages, and convert them into a continuous series of small differentiations, will yield no vertebrate form for which a place does not exist in the general scheme

NOTES

Dr. John Stenhouse, F R S, died on December 31, in the seventy-second year of his age. He was a native of Glasgow, where he was educated and long resided A pupil of Graham and of Liebig, he devoted all his time to research work in the domain of organic chemistry He was a Royal Medallist of the Royal Society, LL.D of Aberdeen, and one of the founders of the Chemical Society On removing to London he was appointed Lecturer on Chemistry in St. Bartholomew's Hospital, London, but was obliged to resign in 1857, owing to a severe attack of paralysis. This however did not deter him from continuing his scientific studies, which were a labour of love to him He was the inventor of the charcoal respirator, of the charcoal ventilator for sewers, and of a process for rendering fabrics waterproof by means of paraffin In 1865 he succeeded Dr Hofmann as non-resident assayer to the Royal Mint, but was deprived of the appointment when the office was abolished by Mr. Lowe in 1870.

On the 3rd inst Mr John Thomas Towson died at his residence in Liverpool, in his seventy-seventh year. Mr. Towson was connected with the early history of photography, but in 1846 he devoted his thoughts to navigation, especially to determining the quickest routes across the ocean to distant countries. With this object he constructed a set of tables for facilitating the practice of great circle sailing, and at the British Association in 1854 Mr Towson aided Dr. Scoresby in directing the attention of the scientific section to the importance of investigating more fully the subject of the deviation of the compasses on board iron ships The result of this discussion was the formation of the Liverpool Compass Committee The observations and the deductions resulting from them were embodied in three reports, "presented to both Houses of Parliament by command of Her Majesty." In 1863 Mr. Towson was instructed by the Board of Trade to prepare a manual on the deviation of the compass, which was subsequently published at the expense of the Board, under the title of "Practical Information on the Deviation of the Compass; for the use of Masters and Mates of Iron Ships"

We are glad to learn that Prof. MacOwan, late of Gill College, Somerset East, has accepted the post of Director of the Botanic Garden, Cape Town He will also lecture at the South African College. The appointment of a man whose long and enthusiastic devotion to South African botany has earned him a wide reputation is to the credit of the Cape Government, and is of good omen for the scientific future of the Cape Botanic Garden This has never yet attained the position which it would naturally derive from the resources of one of the most interesting floras in the world

Dr. W Feddersen of Leipzig is preparing a supplement to Poggendorff's well known biographical dictionary Many of our readers will receive during the next few days circulars asking them to answer a few questions as to their scientific life and labours As the great utility of such a work lies in the completeness of the information it supplies, we trust that every one will fill up the answers to the questions as completely as is in his power, and that neither false modesty nor carelessness will create a gap in the work

Prof Corfield's lectures on Health to ladies will commence to-day, January 6, by an Introductory Lecture at 3 p m., and will be continued on Tuesdays and Thursdays at the same hour Ladies are admitted free to the Introductory Lecture.

Herr Robert Oppenheim of Berlin announces the forthcoming publication of a "Grundriss der Anatomie des Menschen," by Prof Ad Pansch of Kiel

The Reale Istituto Lombardo has awarded two sums of 1500 lire, on the Brambilla foundation, (1) to the Milanese Committee of Animal Vaccination for founding a vaccinogenic establishment in Milan, and (2) to S. Bassolini for establishing in Milan a manufactory of white lead colours and varnishes On the Fossati foundation a sum of 2000 lire has been awarded to Dr Golgi for studies on the fine anatomy of central organs of the nervous system, and 1000 lire to Drs Tenchini and Staurenghi for researches in the anatomy of the cerebellum, the Pons Tarini, &c A list of prizes now open to competition will be found in the *Rendiconti* of the Institute, vol xiii, fasc xviii The subjects have nearly all been previously published (We note that one is "Studies on the Telephone") The prizes vary in value from 500 to 4000 lire Foreigners may compete, and memoirs must be written in Italian, French, or Latin.

The Transit of Venus Commission has already met at the French Academy of Sciences, as usual under the presidency of M. Dumas, but no resolution was come to A number of scientific men have already offered themselves as observers.

Baron Nordenskjöld arrived at St Petersburg on Saturday, and was received at the station by the Swedish Ambassador and delegates from the Russian societies In the course of the day he was received at the Foreign Office, and is to be *fêted* by the Municipality and the learned societies

THE dates for some of the papers which will be read at the Society of Arts before Easter next have been announced. The following are set down for the ordinary meetings (Wednesday evenings):—January 12 A Sanitary Protection Association for London, by W. Fleeming Jenkin, F.R.S. (On this evening Prof. Huxley will preside.) January 19 Causes of Success and Failure in Modern Gold-Mining, by A. G. Lock February 23: Recent Advances in Electric Lighting, by W. H. Preece March 2 Flashing Signals for Lighthouses, by Sir William Thomson, F.R.S. March 9: Improvements in the Treatment of Esparto for the Manufacture of Paper, by William Arnot, F.C.S. March 16: The Manufacture of Aerated Waters, by T. P. Bruce Warren In the Indian Section (Friday evenings), the following will be read:—January 21: Forest Conservancy in India, by Sir Richard Temple, Bart., G.C.S.I. February 11 The Gold-Fields of India, by Hyde Clarke. March 4: The Results of British Rule in India, by J. M. Maclean. March 25: The Tenure and Cultivation of Land in India, by Sir George Campbell, K.C.S.I., M.P. The dates and Papers for the Foreign and Colonial Section (Tuesday evenings) will be:—February 1 The Industrial Products of South Africa, by the Right Hon. Sir Henry Bartle Edward Frere, Bart., G.C.B., &c. February 22: The Languages of South Africa, by Robert Cust March 15: The Loo Choo Islands, by Consul John A. Gubbins April 5 Trade Relations between Great Britain and her Dependencies, by William Westgarth For the Applied Chemistry and Physics Section (Thursday evenings) the arrangements are as follows:—January 27 A New Mechanical Furnace, and a Continuous System of Manufacturing Sulphate of Soda, by James Mactear February 24, Deep Sea Investigation, and the Apparatus used in it, by J. G. Buchanan, F.R.S.E., F.C.S. March 24 The Future Development of Electrical Appliances, by Prof. John Perry

VARIOUS earthquake shocks in Roumania, Transylvania, Hungary, &c., in the latter days of December, are reported, in Bucharest, on the 23rd of that month at 11 20 a.m., and on the 25th at 5 45 p.m., in Tultscha also, on the 25th, at 5 25 p.m. (direction north-west to south-east), in Fokschau, at 5 5 p.m., pretty strong, duration 8 sec., in Tecucui at 4 51 p.m., two strong shocks, the first lasting 2 sec., the second 4 sec., in Washui (near Tassy), a very violent undulatory shock, in Silistria (Bulgaria), at 3 22 p.m., 20 shocks lasting 1m 20s, in Homorod (Hungary), at 4.18 p.m., duration 5s, direction west to east, in Foldvar (Hungary), at 4 20 p.m., direction north-west to south-east At the same time shocks were felt at various places in the south-east of Transylvania.

IT may be useful to some of our readers to know that the Library of the Society of Telegraph Engineers and of Electricians is open to members of all scientific bodies, and (on application to the librarian) to the public generally. The library is open daily between the hours of 11.0 a.m. and 8 0 p.m., except on Thursdays and on Saturdays, when it closes at 2.0 p.m.

"WHITAKER'S ALMANAC" is undoubtedly a most useful publication, but in the larger edition there is a supplement of miscellaneous information which seems to us to require looking after. Among other things there is a variety of items more or less connected with science There is a "Scientific Summary" consisting of nine lines of introduction (in which the only geological fact mentioned is the discovery of some fossil remains in Essex), followed by selected subjects of general interest, including such items as "Steam Power in Germany," "Forests in Russia," "The World's Gold and Silver," "American Railroad Progress," all looking like so many random newspaper cuttings, but no mention of perhaps the most brilliant scientific event of the year—Mr Graham Bell's "Photophone." In another part of the supplement we have two pages on the "Progress of Astronomical Science"; why this is not included in the "Scientific Summary" the editor perhaps knows. A page is devoted to "Radiant Points of Shooting Stars," two to the "Year's Weather," three to "Earthquakes and Volcanic Eruptions," and three to "Geographical Discovery." The writer of the last-mentioned actually places Mr. Leigh Smith's yacht voyage to Franz Josef Land as "the most remarkable geographical event" of a year which witnessed the successful conclusion of Mr Joseph Thomson's remarkable African Expedition, because he thinks it opens up "a new and apparently feasible route for future Polar research:" does he not mean *search?* Evidently the supplement to this "Almanac" stands in need of editing, and as the whole work is to be reset for next year, perhaps this part will be brought up to the level of the rest of the work

THE *Annuaire* of the Bureau des Longitudes for 1881 has been issued by Gauthier-Villars As usual, it is full of information on a great variety of subjects more or less connected with science.

Land and Water states that the late Mr. Frank Buckland has bequeathed his valuable Museum of Economic Fish Culture to the nation, and on the decease of Mrs Buckland a sum of 5000*l.* will revert to the nation, to be applied for the purpose of founding a professorship of economic pisciculture in connection with the Buckland Museum and the Science and Art Department at South Kensington

A Scottish Fisheries Improvement Association has been formed for the purpose of making an effort to improve by various means the fisheries of the Scotch rivers, which have in recent years considerably deteriorated The president is the Duke of Sutherland, and the chairman of the provisional committee Mr. David Milne Home.

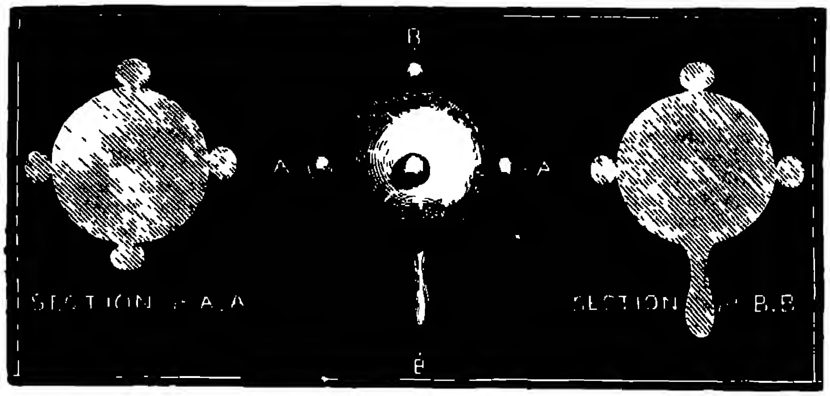
WE have received a copy of the regulations issued by the French Minister of Posts and Telegraphs for the International Congress and Exhibition of Electricity, to be opened at Paris next September Those interested in the Congress should apply to M. le Commissaire Général de l'Exposition Internationale d'Electricité, at the Palace of the Champs Élysées, porte No IV, Paris

MR INNES ROGERS, in a letter to us, calls attention to a list of bamboos published in vol i of the *Garden*, which are found to be hardy under cultivation, and to the fact that several kinds, chiefly from China and Japan, grow in Battersea Park, Kew Gardens, &c He further instances as hardy plants a Cactus from the Rocky Mountains, Begonia from the Andes, the well known *Chamærops excelsa*, *Ficus repens*, and a Mesembryanthemum acclimatised at Scilly, and believes that the fixity of continents through long geological periods would cause tropical species in spreading to adapt themselves to temperate conditions. He thinks that the Gulf Stream may have brought tropical seeds to Bournemouth, and that a most trifling change of climate would have made them thrive there

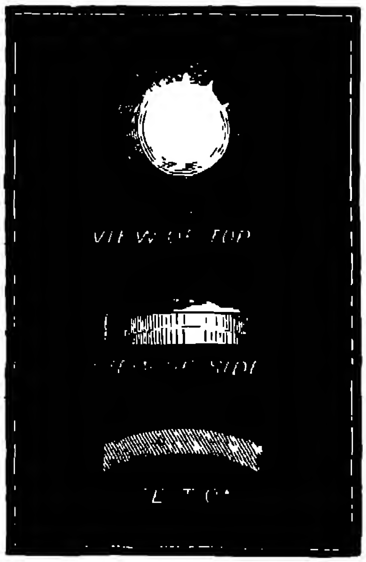
A NEW illustrated archæological review will soon be published at Naples by MM Augusto Mele and Enrico Abeniacco. It will be in French, and its title will be "Pompeii" The object of the new publication is to excite in wider circles a vivid interest for the excavations at Pompeii, Herculaneum, &c., as well as for archæology generally

IN the Austrian "Engineers and Architects Union" at Vienna, a new aeronautical department has been created, with the object of discussing and solving aeronautical problems and questions both theoretically and in practice, as well as making the necessary experiments. The application of aeronautics to meteorological science forms a special study of the department.

To the October number of *Symons's Monthly Meteorological Magazine* Col. Foster Ward writes describing some remarkable hailstones that fell during a slight thunderstorm at Partenkirchen, Bavaria, at 6 p.m. on August 21. He was on a mountain about 3000 feet above the village, and saw the cloud (a small one) pass over the valley below. There were several peals of thunder, but there was no visible lightning, owing, he concludes, to the sun's brightness. "On arriving near home, I met a friend who told me it had been hailing 'tadpoles' and 'acidulated drops.' There had been little or no rain and no visible lightning, and



the hailstones fell at intervals and about six feet apart. There were very few of them, my family only picking up twenty in a space occupied by a full-sized lawn tennis court. My son made a sketch of their shape and size, which I inclose. The greater part were of the 'tadpole' shape and were clear as glass, perfectly round, the five knobs being at equal distance from one another. The flat stones had more or less a slight nucleus of snow in the convex portion of the stone. My wife and three daughters, and two ladies staying with us, say that the stones looked just like a lady's hand looking glass, with a knob at the top and on either



side for ornament. More than twenty, perhaps thirty, were picked up of this shape. Of these about two-thirds were studded, the rest plain, with only the tail or handle, the thinnest part of it being near the body of the stone, as in sketch. The studs were all symmetrically placed. There were from three to five in each stone besides the handle. When there were less than five they occupied the same positions as if the five had been complete. In some cases the handle appeared to have been knocked off. The drops were more numerous, were *all* of same shape, convex at the top, the bottom being concave (like a small china painting palette)."

The total completion of the St. Gothard tunnel will very likely take place in July of this year; the railway is to be opened on July 1, 1882. The mail bags are even now carried through the tunnel by messengers when rough weather prevails upon the mountain. On December 21 the first mail-bag was so carried through the tunnel, and it took four hours to convey it from Göschenen to Airolo.

GEOGRAPHICAL NOTES

At the Second International Polar Conference at Berne all the leading nations of Europe were represented except England. The leading stations have been definitely decided on. Austria undertakes to establish a station in northern Novaya Zemlya, at the expense of Count Wilczek; Denmark has selected Upernivik; Germany New Georgia for the Antarctic, and Jan Mayen or East Greenland for the Arctic regions; Norway, Bossekop in Finmark; Holland the south-east coast of Novaya Zemlya, or the coast of Siberia, between the mouth of the Yenisei and Cape Taimyr; Russia has selected two stations, the mouth of the Lena and the New Siberian Islands. Even Switzerland, which has not even a sea-board, hopes to take part in the international movement, by establishing a station at Mossel Bay, in Spitzbergen. The expedition to be sent out by Italy to the Antarctic region under Lieut. Bove is to some extent connected with this scheme, and no doubt France will ultimately be compelled to take her part. As to England, there has hitherto been no sign that as a nation she is even interested in a scheme so full of important issues for science and navigation.

In a recent paper to the R. Accademia dei Lincei, Signor Guido Cora, a member of the International Polar Committee, urges the importance of the enterprise under consideration, and of Italy sharing in it. He considers the Antarctic zone as the more suitable one for Italy, as being nearer regions where Italians form a large portion of the population and conduct an extensive commerce; moreover the south has a brilliant record of geographical exploration by Italians in the sixteenth century, and the recent project of an Antarctic exploring expedition has drawn enthusiastic attention. For the temporary scientific observatory which the Italian Government is recommended to plant in 1882 (in harmony with the large scheme), S. Cora suggests one or other of three places:—1. Port Spence, on the east coast of Coronation Island in the Southern Orkneys, at about 60° 50′ S. lat., and 45° 45′ W. long. 2. Cape Lookout, on the south coast of Elephant Island, in the north-east part of the Southern Shetland group, at about 61° 17′ S. lat. and 55° 15′ W. long. (a station at either place would serve well as a base of operations for the Italian Exploring Expedition). 3. In the case of means being inadequate for a station at either of the two places named, S. Guido recommends some one of the islands close to Cape Horn. Supposing that the transport would be by a Government vessel destined to the naval station

in South America, it is calculated that the cost of the observatory would amount to 70,000 or 80,000 lire, of which 10,000 would be for instruments, and the remainder would provide three dwelling-houses, salaries of four scientists, two assistants, and two servants, food, &c. This is calculated for an absence of sixteen months, twelve of which would be occupied in observations.

THE Geographical Society's *Proceedings* this month contains three papers relating to Africa, the first of which is Sir Bartle Frere's, on Temperate South Africa. This, as now printed, embodies some useful statistical information and is illustrated by a general map of South Africa The other two papers bring some additions to our knowledge of the geography of West Africa, Mr. Comber giving a short sketch of his recent journeys in the interior of Congo, and Mr Milum an account of his travels in the Niger region. The former is accompanied by an excellent map of the neighbourhood of San Salvador and of the course of the River Congo from Stanley Pool to the sea. The final report of the Executive Committee of the African Exploration Fund is published, together with a statement of receipts and expenditure In the Geographical Notes extracts are given from a letter by Mr. Hore of Ujiji, on the long-continued rise of the waters of Lake Tanganyika, which he seems to connect with earthquake-movements. Mr. Hore is shortly about to return to England, so that we shall probably hear more on this subject before long Among the other notes we may call attention to those on the River Okavango, the survey of Eastern Palestine, and the United States' Survey operations in the neighbourhood of Behring Strait Increased attention, we note, is being paid to the proceedings of foreign geographical Societies, those of the French Society being very fully reported.

M VOSSION, who, it will be remembered, spent some time in Burmah, and not long since read papers on that country before the French Geographical Societies, has lately gone to Egypt to take up the Vice-Consulship of Khartum During his stay there he is to pay special attention to the slave trade, and to the best means of opening up commercial relations with the Sudan.

CAPT SERRA CARRACIOLI left Naples on November 23, 1880, for the Bay of Assab, having undertaken a mission, under the auspices of the Club Africano, to inquire into the possibility of developing commerce there and with the natives of the interior The Club Africano is desirous of establishing pearl, mother-of-pearl, and sponge fisheries in the Bay of Assab While funds are being raised for more extensive operations, this expedition is sent out to make a careful survey of the region, to form a depôt for further expeditions, whether commercial or scientific, and to make other preparations The expense is expected not to exceed 600*l* It is also stated that the Italian Geographical Society have made arrangements for the establishment of a meteorological station at the Bay of Assab The October part of the *Bolletino* of the Italian Geographical Society contains a long and valuable memoir by Signor C. de Amezaga on Assab.

AT the last meeting of the Lyons Geographical Society M. Coillard gave an interesting account of his twenty years' experiences in South Africa. He was engaged for some time on a missionary expedition in the Upper Zambesi region, and was probably the means of saving Major Serpa Pinto's life, afterwards accompanying him in some of his explorations. As no particulars have yet been published of M. Coillard's geographical work in this region, it is to be hoped that his paper will be given in full in the Lyons Society's *Bulletin*

IN last week's *Missions Catholiques* we have the concluding instalment of some interesting and useful papers by the Bishop of Vancouver, entitled "Une Visite Pastorale dans le Territoire d'Alaska." Père Montiton's notes on the traditions and customs of the Sandwich Islands are also continued.

THE January number of *Good Words* contains the first of a series of papers by Mr. Joseph Thomson on his experiences during his recent journey in East Central Africa. The present instalment deals with the preparatory journey which he made with Mr Keith Johnston to Usambara, and furnishes interesting notes on the country traversed.

THE Alexandria Correspondent of the *Daily News* tells us that M. Chower, formerly a newspaper correspondent in Turkey, Kurdistan, Armenia, and Albania, started on December 31, "to explore Africa from north to south, from Alexandria to the Cape of Good Hope." *Bon voyage*

THE death is announced of Dr. Fr. Mook, the well-known African traveller, who accompanied Dr. E. Riebeck on his expedition, which started in August last for the East. Dr. Mook died at Jaffa shortly before Christmas.

WE have received parts 17 to 22 of the new edition of Stieler's Hand-Atlas, with three supplementary parts containing in eight sheets a very fine map of the Basin of the Mediterranean Sea.

THE Dutch Committee, which arranged the North Polar Expeditions of the last few years, held a general meeting at the Hague a short time ago, when the resolution was passed to collect funds for the organisation of a fourth Arctic expedition In the meantime the Committee will endeavour to have a steamer built for this purpose.

ON HEAT CONDUCTION IN HIGHLY RAREFIED AIR [1]

THE transfer of heat across air of different densities has been examined by various experimentalists, the general result being that heat conduction is almost independent of pressure. Winkelmann (*Pogg Ann.* 1875, 76) measured the velocity of cooling of a thermometer in a vessel filled with the gas to be examined. The difficulty of these experiments lies in the circumstance that the cooling is caused not only by the conduction of the gas which surrounds the cooling body, but that also the currents of the gas and, above all, radiation play an important part Winkelmann eliminated the action of currents by altering the pressure of the gas between 760 and 1 millim. (with decreasing pressure the action of gas currents becomes less), and he obtained data for eliminating the action of radiation by varying the dimensions of the outer vessel He found that, whereas a lowering of the pressure from 760 to 91 4 millims there was a change of only 1 4 per cent. in the value for the velocity of cooling, on further diminution of the pressure to 4·7 millims there was a further decrease of 11 per cent, and this decrease continued when the pressure was further lowered to 1 92 millim.

About the same time Kundt and Warburg (*Pogg Ann.* 1874, 5) carried out similar experiments, increasing the exhaustion to much higher points, but without giving measurements of the pressure below 1 millim They inclosed a thermometer in a glass bulb connected with a mercury pump, and heated it to a higher temperature than the highest point at which observations were to be taken, then left it to itself, and noted the time it took to fall through a certain number of degrees. They found that between 10 millims and 1 millim the time of cooling from 60° to 20° was independent of the pressure, on the contrary, at 150 millims pressure the rate was one-and-a-half times as great as at 750 millims Many precautions were taken to secure accuracy, but no measurements of higher exhaustions being given the results lack quantitative value

It appears, therefore, that a thermometer cools slower in a so-called vacuum than in air of atmospheric pressure. In dense air convection currents have a considerable share in the action, but the law of cooling in vacua so high that we may neglect convection has not to my knowledge been determined Some years ago Prof. Stokes suggested to me to examine this point, but finding that Kundt and Warburg were working in the same direction it was not thought worth going over the same ground, and the experiments were only tried up to a certain point, and then set aside. The data which these experiments would have given are now required for the discussion of some results on the viscosity of gases, which I hope to lay before the Society in the course of a few weeks, I have therefore completed them so as to embody the results in the form of a short paper

An accurate thermometer with pretty open scale was inclosed in a $1\frac{1}{2}$ inch glass globe, the bulb of the thermometer being in the centre, and the stem being inclosed in the tube leading from the glass globe to the pump.

Experiments were tried in two ways:—

I The glass globe (at the various exhaustions) was immersed in nearly boiling water, and when the temperature was stationary it was taken out, wiped dry, and allowed to cool in the air, the number of seconds occupied for each sink of 5° being noted.

II. The globe was first brought to a uniform temperature in a vessel of water at 25°, and was then suddenly plunged into a large vessel of water at 65°. The bulk of hot water was such that the temperature remained sensibly the same during the continuance of each experiment. The number of seconds required for the thermometer to rise from 25° to 50° was registered as in the first case

[1] Abstract of a Paper read before the Royal Society by William Crookes, F R S, December 16, 1880.

It was found that the second form of experiment gave the most uniform results; the method by cooling being less accurate, owing to currents of air in the room, &c.

The results are embodied in the following Table:—

(Rate of Heating from 25° to 50°)

TABLE I

Pressure	Temperature	Seconds occupied in rising each 5°	Total number of seconds occupied
760 millims.	25°	0	0
	25 to 30	15	15
	30 to 35	18	33
	35 to 40	22	55
	40 to 45	27	82
	45 to 50	39	121
1 millim.	25°	0	0
	25 to 30	20	20
	30 to 35	23	43
	35 to 40	25	68
	40 to 45	34	102
	45 to 50	48	150
620 M.[1]	25°	0	0
	25 to 30	20	20
	30 to 35	23	43
	35 to 40	29	72

	40 to 45	90	247
	45 to 50	165	412

There are two ways in which heat can get from the glass globe to the thermometer—(1) By radiation across the intervening space; (2) by communicating an increase of motion to the molecules of the gas, which carry it to the thermometer. It is quite conceivable that a considerable part, especially in the case of heat of low refrangibility, may be transferred by "carriage," as I will call it to distinguish it from convection which is different, and yet that we should not perceive much diminution of transference, and consequently much diminution of rate of rise with increased exhaustion, so long as we work with ordinary exhaustions up to 1 millim. or so. For if, on the one hand, there are fewer molecules impinging on the warm body (which is adverse to the carriage of heat), yet on the other the mean length of path between collisions is increased, so that the augmented motion is carried further. The number of steps by which the temperature passes from the warmer to the cooler body is diminished, and accordingly the value of each step is increased. Hence the increase in the difference of velocity before and after impact may make up for the diminution in the number of molecules impinging. It is therefore conceivable that it may not be till such high exhaustions are reached that the mean length of path between collisions becomes comparable with the diameter of the case, that further exhaustion produces a notable fall in the rate at which heat is conveyed from the case to the thermometer.

The above experiments show that there is a notable fall, a reduction of pressure from 5 M. to 2 M. producing twice as much fall in the rate as is obtained by the whole exhaustion from 760 millims. to 1 millim. We may legitimately infer that each additional diminution of a millionth would produce a still greater retardation of cooling, so that in such vacua as exist in planetary space the loss of heat—which in that case would only take place by radiation—would be exceedingly slow.

[1] M = millionth of an atmosphere.

SCIENTIFIC SERIALS

Journal de Physique, December, 1880.—Note on magic mirrors, by M. Bertin.—On some applications of articulated systems, by M. Robin.—Experiments on the discharge in rarefied gases, by M. Righi.—Notice on the life and works of M. Almeida.

Archives des Sciences Physiques et Naturelles, November 15.—Meteorological *résumé* of the year 1879 for Geneva and the Great St. Bernard, by M. Plantamour.—Disinfection of vehicles, plants, collections of natural history, and various objects with anhydrous sulphurous acid, by Dr. Fatio.—Observations on a memoir of M. Schönn, by M. Soret.—On the phenomenon of hydration in peptonisation of albuminoid substances, by Dr. Danilewsky.—Notes on the winds of mountains, by M. Pittier.—Case of diplopia, by Prof. Wartmann, &c.

Reale Istituto Lombardo di Scienze e Lettere. Rendiconti. vol. xiii. fasc. xviii., November, 1880.—This number contains lists of prizes awarded and offered.

Atti della R. Accademia dei Lincei, vol. v. fasc. 1 (December 5, 1880).—New studies on the nature of malaria, by SS. Cuboni and Marchiafava.—Graphic determination of the elastic force relative to plane elements passing through a point, by S. Modigliano.—On the geological nature of strata met with in the tubular foundations of the new iron bridge built on the Tiber at Ripatta, and on the *Unio sinuatus*, Lamk., there found, by S. Meli.—On the structure of the envelope of the ova of some fishes, by S. Leporì.—On the preservation of man in countries of malaria, by S. Tommasi Crudeli.—On bilinear ternary forms, by S. Battaglini.—On the projected stations for systematic physical observations in polar regions, by S. Cora.—On a cebocephalic capuchin monster, by S. de Sanctis.—On the recent restoration of the scholastic and tomistic philosophy, by S. Ferri.

SOCIETIES AND ACADEMIES

LONDON

Photographic Society, December 14, 1880.—J. Glaisher, F.R.S., president, in the chair.—Papers were read by Prof. T. E. Thorpe, F.R.S., on a simple and expeditious method of preparing pyrogallol for dry plate development. The method proposed is to put dry gallic acid and glycerine into a flask, which is then heated to 200° on a sand tray, as long as bubbles of carbon dioxide are seen to be formed in the liquid. The gallic acid soon dissolves and is entirely converted into the theoretical quantity of pyrogallol, viz., 80 per cent.—By Capt. Abney, R.E., F.R.S., iodide and ammonia in gelatine emulsions. It was stated that iodides in gelatine bromide emulsion kept the silver salts from being deposited upon the shadows, as also that there is freedom from decomposition of the film, and tendency to red fog, and more light can be used in preparing and developing the plates.—And also by Capt. Abney on a photographic sunshine recorder. This consisted of a semi-cylindrical box with a flat lid, in the centre of which is a small hole; round the inside of the cylinder strips of sensitive paper are

fixed; the instrument is then so placed that the sun, the hole, and the centre line of the paper are in the same plane, so that as the sun moves its track will be recorded on the paper.

Victoria (Philosophical) Institute, January 3.—A paper on the early destinies of man was read by Mr. J. E. Howard, F.R.S., F.L.S., &c., in which he considered them in relation to science, to philosophy, and also to religion, and gave an analysis of the various known traditions in regard to the early history of man in all ages and in all countries.

MANCHESTER

Literary and Philosophical Society, December 14, 1880.—E. W. Binney, F.R.S., F.G.S., president, in the chair.—Boulder stones as grave stones. The president, when visiting Ashton-under-Lyne the other day, observed in the churchyard on the Manchester Road a greenstone boulder used as a tombstone over the grave of a son of an alderman of that borough. This is the first instance where he had seen a boulder stone used for such a purpose, and it is one where they may not only be preserved, but exhibited to the public.—The land subsidence at Northwich, by Thomas Ward.—Some endeavours to ascertain the nature of the insoluble form of soda existing in the residue left on causticising sodium carbonate solutions with lime (Part ii.), by Watson Smith, F.C.S., Assistant Lecturer on Chemistry in the Owens College, and W. I. Liddle. Communicated by Prof. C. Schorlemmer, F.R.S.

PARIS

Academy of Sciences, December 27, 1880.—M. Edm. Becquerel in the chair.—M. Faye presented the *Annuaire du Bureau des Longitudes* for 1881, and noted the improvements.—On the series of Fourier and other analytical representations of functions of a real variable, by M. Hermite.—On the velocity of propagation of light, by M. Cornu. He controverts M. Gouy's ideas.—On the chlorhydrates of metallic chlorides, and on the reduction of chlorides by hydrogen, by M. Berthelot. These chlorhydrates play an important part in chemical mechanics, by reason of their considerable heat of formation and their state of dissociation.—On an oxygenated base derived from aldol, by M. Wurtz.—Effects of tearing out the intracranial part of the glosopharyngeal nerve, by M. Vulpian. This action does not (in the cat) appreciably affect the influence of nerves which act as direct vaso-dilators on the mucous membrane of the buccal cavity, except as regards the effects of excitation of the nerve itself on the posterior region of the dorsal face of the tongue.—Observations on some animals of Madagascar, by M. Milne-Edwards. This relates to an important collection of mammalia and birds by M. Humblot, sent to the Museum of Natural History. They show the modifications of species well. M. Humblot has sent to the menagerie two living Aye-Ayes, two Makis, &c. (offering many points of interest).—Order of production of the first vessels in the ear of *Lolium* (first part), by M. Trécul.—M. Sella was elected Correspondent in Mineralogy in room of the late Prof. Miller, and Mr. Warren De La Rue in Astronomy in room of the late Mr. MacLear.—Observations on phylloxera, by M. Lichtenstein. He indicates ten or eleven animal parasites of phylloxera, but does not regard any of these hopefully as a means of stopping the disease. He is studying the effect of inoculation with cryptogams; the results are not yet decisive.—Determination of the time of rotation of Jupiter, by M. Cruls. From observations of the spot at Rio Observatory during 1083 rotations he obtains the number 9h. 55m. 36s. in mean solar time. Mr. Pratt, at Brighton, got the number 9h. 55m. 33·91, from 321 rotations. Thus the time of Jupiter's rotation seems to be known to within a second.—On Hartwig's comet (*d* 1880), by MM. Schulhof and Bossert. They consider the period 6⅔ years must be rigorously excluded.—Solar observations at the Royal Observatory of the Roman College during the third quarter of 1880, by P. Tacchini. There was increased activity. The number of spots was double that in the preceding quarter, and there was hardly a day without them. The number of faculæ in September was extraordinary. In the case of the protuberances (also more frequent) there was a maximum in each hemisphere between 50° and 60° and another between 20° and 40°.—Observations on Swift's comet (*e* 1880) at the Royal Observatory of the Roman College, by P. Tacchini.—On the contact of conics and surfaces, by M. Moutard.—On a new method of producing intermittent luminous signals, by M. Crova. M. Leverrier and he used in 1870-71 a very similar arrangement to M. Mercadier's. They found that they must use oxygen under weak pressure and give the pipe a wide orifice; also that the key must be pressed and released very suddenly.—On a new electrodynamic theorem, by M. Cabanellas.—Regulator of pressure for vapours, by M. D'Arsonval. The triple problem here solved is (1) keeping constant, in a boiler, the pressure of a given vapour whatever the discharge; (2) using the combustible gas only in proportion to the vapour expended; (3) making the instrument quite automatic without danger of explosion. There is a membrane of caoutchouc between two metallic rings; its lower surface is in contact with the vapour, and on its upper rests a metallic disk with rod and lever like that of a safety valve. At the upper surface of the disk debouches a tube which brings the gas; there is another tube above through which the gas goes to the boiler.—On a new derivative of sulphide of nitrogen, by M. Demarçay.—On a platinous hypophosphite, by M. Engel. This is got by action of phosphuretted hydrogen on tetrachloride of platinum.—On borotungstates of sodium, by M. Klein.—On some facts relative to the transformation of chloral into metachloral, by M. Byasson.—On the products of oxidation of cholalic acid.—On the excretion by urine of sulphur incompletely oxidised, in various pathological states of the liver, by MM. Lépine and Flavard.—On visual sensibility and its relations with luminous and chromatic sensibility, by M. Charpentier. What he calls visual sensibility corresponds to visual acuteness, but while the latter is expressed by the smallest angle under which one can recognise as distinct two luminous points, the former is expressed by the smallest quantity of light which renders those two points distinct. The order of increasing complexity is, luminous sensibility, chromatic sensibility, visual sensibility.—On the distribution of light in the solar spectrum (spectrum of Daltonians), by MM. Macé and Nicati. These observations appear to give certain proof of the existence of two distinct kinds of Daltonians, also to support the Young-Helmholtz theory of colours, and to contradict Hering's.—Reactions of the motor-zone of the brain in animals paralysed by curare, by MM. Couty and De Lacerda.—On passage of red corpuscles into the lymphatic circulation, by M. Laulanie. This is effected by obliteration of veins. The effect appears in about twelve hours, and the number of corpuscles increases to about the fortieth hour.—On the internal and external sheaths of hairs, by M. Renaut.—New researches on the organs of touch, by M. Ranvier. By observing the tactile corpuscles in infants and children he has come to a better appreciation of their structure.—On the sensitive nerve-termination in the skin of some insects, by M. Viallanes. Examining larvæ of *Musca* and *Eristalis*, he finds under the hypodermis an extremely rich plexus of ganglionic cells, connected on one hand with the chief nerve-centres, and on the other with sensitive terminal nerve-branches.—On the sensorial cylinders of the internal antenna of crustaceans, by M. Jourdain. While these have undoubtedly the characters of an organ of sense, they cannot (anatomically, and independently of all physiological experiment) be said to be affected with olfaction.—Marine molluscs living on the coasts of Campbell's Island, by M. Filhol.—Examination of the marine fauna of the upper sands of Pierrefitte near Etampes, by M. Meunier.—On the age of upheaval of the district of Bray, by M. Dollfus.—On the crystalline schists of Brazil and the red earths which cover them, by M. Gorceix.

BAROMETRIC CYCLES

ABOUT twelve years ago Mr Baxendell of Manchester gave evidence of a connection between the convection-currents of the earth and the state of the sun's surface, and the subject has since been much discussed by meteorologists from various points of view.

Amongst these Mr Meldrum of the Mauritius Observatory has brought forward much evidence in favour of a connection between sun-spots on the one hand and rainfall and cyclones on the other. Still more recently the Indian meteorologists, including the names of Messrs Archibald, Blanford, Broun, Charles and Frederick Chambers, Eliot, and Hill have studied with much success the abnormal variations of barometric pressure in the tropics. Of these the researches of Mr F. Chambers are particularly interesting[1] as exhibiting a very close relation between such barometric fluctuations and the state of the sun's surface.

The chief principle underlying these investigations is sufficiently obvious. We know that the marked differences in barometric pressure which exist between various portions of the earth's surface must be due to the sun, if therefore the sun be in reality variable we should naturally expect these differences to vary likewise in such a way as to be strengthened when the sun is most powerful and weakened when he has least influence. In accordance with this way of regarding things, Mr. Chambers in 1876 pointed out that the abnormal variations of the monthly mean barometric pressure at Bombay in that year were mainly variations in the intensity of the usual seasonal movements, while in 1877 he attributed the uniformly high barometric pressure and the deficient rainfall of that year to a weak development of the equatorial belt of minimum pressure, probably induced by a diminution of the solar heat.

In a diagram attached to his first communication Mr Chambers compares the curve of solar-spotted area with other curves denoting the barometric pressure at various widely-distributed tropical stations, from which we can clearly see that there is a very marked resemblance between the salient points of the various curves on the hypothesis that a large amount of sun-spots corresponds to a low barometer. But besides this it appears that the epochs of maximum and minimum barometric pressure lag considerably behind the corresponding epochs of minimum and maximum solar-spotted area, and that this lagging behind is greater for easterly than for westerly stations, or in other words the abnormal barometric variations in the tropics may be said to travel at a very slow rate round the earth from west to east.

Perhaps the subject of greatest practical importance in these communications is the discussion regarding Indian famines and their connection with sun-spot minima—a connection first brought to light by Dr. Hunter. Mr Chambers sums up his conclusions on this point as follows:—

1. Variations of the solar-spotted area are succeeded months afterwards by corresponding abnormal barometric variations, a high barometer corresponding to a minimum of sun-spots.

2. Famines follow in the wake of curves of high barometric pressure.

Finally two methods are indicated by which early intimation of the approach of those meteorological disturbances which are attended by famines may possibly be obtained.

1. By regular observation of the solar-spotted area, and early reduction of the observations, so as to obtain early information of current changes going on in the sun.

2. By barometric observations at stations differing widely in longitude and the early communication of the results of stations situated to the westward.

While it thus appears that the evidence in favour of a connection between the state of the sun's surface and the meteorology of the earth is continually accumulating it may not be amiss to review briefly the present position of the problem.

In the first place Mr Meldrum, as already mentioned, has given evidence that in numerous stations the rainfall is greater about times of maximum than about times of minimum sun-spot frequency.

Secondly. Through his labours and those of M. Poey we have reason to believe that there are more cyclones in the Indian Ocean and hurricanes near the West Indies during times of maximum than during times of minimum sun-spot frequency.

Thirdly. There is the connection between the barometric fluctuations of the tropics and the state of the sun's surface which has just been pointed out.

Fourthly. From investigations in which I have been recently engaged there is reason to suppose that sun-spot inequalities of short duration are followed by corresponding inequalities in the diurnal temperature range of Toronto in such a way that a large amount of sun-spots slightly precedes a large temperature range.

Fifthly. To go from meteorology to magnetism there is the well known connection first observed by Sabine, in virtue of which the diurnal oscillations of the magnet are greatest about times of maximum sun-spots. And I may add that magnetic maxima lag behind sun-spot maxima, while there are also indications that magnetic weather, like meteorological weather, travels from west to east.

We thus perceive how strong the evidence is in favour of some connection between the state of the sun's surface and terrestrial meteorology, while at the same time it is unmistakably indicated by all elements that this connection is of such a nature as to imply that the sun is most powerful when there are most spots on his surface. Add to this that the spectroscopic observations of Lockyer and others tend in the same direction, as well as such actinometric results as we have been able to procure, chiefly through the labours of Mr J. H. Hennessey at Dehra Dhoon and Mussoorie.

In fine this hypothesis is rapidly emerging, if indeed it has not already emerged, from the regions of mere conjecture.

But here it is necessary to bear in mind the following considerations. Prof. Stokes has pointed out that the problem before us really involves two questions, which may be stated as follows:—Firstly, do the changes which take place in the sun's surface correspond to changes in

[1] See NATURE, November 25 and December 2, 1880.

the meteorology and magnetism of the earth, and if so, does an increase of spotted area denote an increase of solar activity, or the reverse?

This question, I have already remarked, seems to be rapidly emerging from the realms of mere conjecture But there is still another question, for we have to inquire whether these recognised solar inequalities bear all or any of the marks of a true periodicity Now this is still *sub judice*, while at the same time it is a point of very great practical importance. For if the solar inequalities be found on investigation to present none of the marks of a true periodicity, we can hardly hope ever to be able to hazard a prediction regarding the state of the sun, and our knowledge of the eleven-yearly period, as it is called, will continue to remain very much the same as at present But on the other hand, if we find that there are true solar periods and succeed in disentangling them, we may hope to arrive at some measure of predicting power As I have said, this question is still unsettled, and will of course present itself in different ways to different observers Meanwhile all we can do is to observe and register the actual state of the sun's surface, and inasmuch as the meteorological occurrences of greatest practical issue do not precede but follow solar phenomena by several months or more, we may thus arrive at a limited amount of practical prevision.

I do not however feel sure that the method of doing this which Mr Chambers has indicated is in reality the best, for I should imagine that unexceptionable observations of the sun's intrinsic heat-giving power, if these could be obtained, would furnish a more trustworthy instrument of prevision than the sun-spot record.

Then with regard to indirect observations No doubt those of the barometer are very immediately connected with the occurrences which we wish to foresee, but yet I think it possible that well-selected magnetic observations might ultimately be found to follow more quickly upon solar changes as well as to indicate with a less amount of local influence the true state of the sun

These however are points that can only be settled by future research Meanwhile it is extremely gratifying to all who take an interest in this subject to reflect that it is engrossing the attention of observers in all parts of the world.

BALFOUR STEWART

LIFE OF LIVINGSTONE

The Personal Life of David Livingstone, LL.D., D.C.L Chiefly from his Unpublished Journals and Correspondence in the Possession of his Family. By William Garden Blaikie, D D., LL.D, New College, Edinburgh. Portrait and Map. (London. Murray, 1880)

WHEN the news of Livingstone's sad death on the swampy shore of Lake Bangweolo reached this country, and when his body was brought home by his faithful followers to be honoured as the nation honours its greatest and best; and again on the publication of his "Last Journals," we spoke in some detail of the great work he accomplished, and expressed our opinion as to the position which that work had earned for him. The years that have elapsed since Livingstone died at his post have only confirmed the judgment of the nation; and now that Dr. Blaikie's admirably-compiled "Personal Life" enables us to fill up the portrait, it will be seen that the man was as great as his work. Necessarily the missionary and religious side of Livingstone's character and work occupies a large place in this volume; this was to be expected from a writer who is a prominent leader in the Free Church of Scotland. But we do not think there is any excess in this direction, these were genuine and ever-present aspects of the character of the man, and Dr Blaikie does not give them place at the expense of any other feature He has honestly endeavoured to give us a complete portrait of his hero, and in this we think he has decidedly succeeded Simplicity and transparency were marked features in Livingstone's character from first to last; delight in simple joys, a boyish love of fun, tenderness of heart and all-embracing charity, strong natural affection, the yearnings of which he could and did sacrifice to his still stronger sense of duty, the whole dominated by an all-conquering determination and perseverance in accomplishing the work which he believed was "given him to do" This is the impression which Dr Blaikie's "Personal Life" gives, and in this it only confirms the impression which is conveyed by a study of Livingstone's own narratives

Dr Blaikie, however, tells us many things which must be new to most of those who knew Livingstone only through his works We learn here how well qualified he was for the work which from early years he seems to have set before himself Livingstone came of a good stock, which, though humble, knew of and had some pride in its ancestry One ancestor fought at Culloden on the side of Prince Charlie, for on the mother's side he had some Highland blood in his veins But the impulsive and sad temperament of the Celt was considerably modified by the practical and hopeful features of the Teutonic blood of his father. The latter was a type of the devout, rigidly honest, intelligent, and comparatively well-read, humble Scotchman, while the mother held the love and respect of her son to the end of her life. The family were poor, and all had to work hard, and early in life young Livingstone had to begin to earn his living in a cotton-mill at Blantyre, near Glasgow, where he was born March 19, 1813 With his first wages he bought a copy of Ruddiman's "Latin Rudiments," and thus early, it is evident, his aspirations went beyond the cotton-mill. His hours were long, but while attending to his "jenny," and till late at night, after his day's work was over, he conned his Ruddiman and other books to qualify himself for a University course His thirst for reading was great, and he devoured all the books that came within his reach Natural science also had its attractions for him, which he indulged by scouring the country when he had time in search of natural history specimens. Dr. Blaikie tells of Livingstone's "conversion" when he was a young man. This, in his case, means that what was instinctive action became thenceforth settled and conscious purpose It was doubtless a proud day both for father and son when the former walked with the latter to Glasgow to see him settled in a humble lodging in order that he might attend the classes at Anderson's College. Livingstone never intended to be a clerical missionary; medicine was the subject of his study in Glasgow, and it was as a medical missionary he intended to accomplish the work of his life. It was only to please his friends and the

London Missionary Society he consented to "ordination" Chemistry seems to have been a favourite subject with him at college, and Dr Blaikie narrates an interesting incident in which Livingstone and James and William (now Sir William) Thomson and Lyon Playfair met together at James Young's (now of Kelly) rooms, to witness some chemical experiment Having been accepted by the London Missionary Society, Livingstone went to London to complete his medical studies, get some lessons in theology, and learn to preach His failure in the latter accomplishment nearly led to his final rejection, and no doubt determined the Society to send him to the rough and humble field of Africa, instead of to China, on which his heart was set The decision must be regarded as in every respect fortunate, though Livingstone had been some time in Africa ere he got over his disappointment. He went out to his work in Africa in 1841, and how anxious he was in every way to qualify himself for that work is shown by the fact that he got the captain of the ship in which he sailed to teach him the use of the quadrant and how to take lunars With a few more lessons in taking observations from Sir Thomas Maclear at the Cape, he became an adept in this kind of work, and Sir Thomas afterwards expressed his astonishment at the almost perfect accuracy of Livingstone's observations in this department He left the Cape as soon as he could and made for Moffat's station at Kuruman Still further north he went, about 250 miles, and settled for some time among the Bechuanas, over whom, as over all other natives with whom he came into contact, he soon acquired great power and influence His idea of a missionary's work was very practical, and rapidly developed and expanded, after he set foot in Africa From the first he gave attention to geography, and his early letters are full of geographical details, illustrated by little sketch maps How early his mind was attracted by the scientific questions connected with the geography of Africa will be seen from the following passage from the work before us —

"The progress of medical and scientific work during this period is noted in a letter to Dr Risdon Bennett, dated 30th June, 1843 In addition to full details of the missionary work, this letter enters largely into the state of disease in South Africa, and records some interesting cases, medical and surgical Still more interesting, perhaps, is the evidence it affords of the place in Livingstone's attention which began to be occupied by three great subjects of which we shall hear much anon - Fever, Tsetse, and 'the Lake' Fever he considered the greatest barrier to the evangelisation of Africa Tsetse, an insect like a common fly, destroyed horses and oxen, so that many traders lost literally every ox in their team As for the Lake, it lay somewhat beyond the outskirts of his new district, and was reported terrible for fever He heard that Mr. Moffat intended to visit it, but he was somewhat alarmed lest his friend should suffer It was not Moffat but Livingstone, however, that first braved the risks of that fever swamp.

"A subject of special scientific interest to the missionary during this period was—the desiccation of Africa On this topic he addressed a long letter to Dr. Buckland in 1843, of which, considerably to his regret, no public notice appears to have been taken, and perhaps the letter never reached him. The substance of this paper may, however, be gathered from a communication subsequently made to the Royal Geographical Society (see *Journal*, vol. xxvii. p. 356) after his first impression had been confirmed by enlarged observation and discovery Around and north of Kuruman, he had found many indications of a much larger supply of water in a former age He ascribed the desiccation to the gradual elevation of the western part of the country. He found traces of a very large ancient river which flowed nearly north and south to a large lake, including the bed of the present Orange River; in fact he believed that the whole country south of Lake 'Ngami presented in ancient times very much the same appearance as the basin north of that lake does now, and that the southern lake disappeared when a fissure was made in the ridge through which the Orange River now proceeds to the sea He could even indicate the spot where the river and the lake met, for some hills there had caused an eddy in which was found a mound of calcareous tufa and travertine, full of fossil bones. These fossils he was most eager to examine, in order to determine the time of the change, but on his first visit he had no time, and when he returned he was suddenly called away to visit a missionary's child, a hundred miles off It happened that he was never in the same locality again, and had therefore no opportunity to complete his investigation"

It was not likely that a man whose mind was filled with such problems would be content to settle down to the dull routine of the work of a common missionary, and count his success by the tale of doubtful "conversions" he could send home to his constituents He kept moving onward from one station to another, getting further and further into the interior, gaining the love of the natives and the hatred of the Boers By his example more than by direct teaching he showed the people the beauty of right living, and taught them many industrial arts which some of them have not lost till this day But his longing was ever northwards, and his eager desire to solve the mystery of Lake 'Ngami It was not till 1849 however that he was able to visit the lake, and his account of the visit first brought him permanently into notice as a working geographer This may be said to have ended the first stage of Livingstone's career, that in which the missionary was predominant It seems to us, however, doubtful whether Livingstone ever intended definitely to settle down to the life of a missionary Even from the beginning, we think, he must have had some vague idea of combining the function of missionary and explorer, always, however, with the one great object in view of bringing Africa under the influences of civilisation and Christianity Shortly after the 'Ngami excursion he became a missionary at large Returning to Cape Town, he sent home his wife and children, and prepared himself for the great work of exploring the Zambesi Proceeding northwards to Linyanti in 1852, he set out on that ever memorable journey to Loanda and across the continent to Quilimane, which stamped him as one of the greatest explorers of all time The story of this and of his subsequent work in the region of Lake Nyassa, and of his many years' wandering all over Central Africa, he has told himself, and Dr Blaikie wisely refrains from introducing more of it than is really necessary to hold together the narrative of his Personal Life. All that Livingstone has done for Africa it is not easy to estimate. It is he more than any other explorer who has filled up the great white blank in the maps of our schoolboy days. His geographical instinct was surer than that of any other man, only once was it seemingly at fault, when he wandered away by Lake

Bangweolo seeking for the "fountains of the Nile", and that one mistake cost him his life Men like Sir Thomas Maclear, Prof Owen, and Sir Roderick Murchison testify to the high value of his observations in various departments of science, and it is due to his example and initiative that Africa is now covered with an army of explorers. Livingstone was a man who was consumed with a definite and noble purpose, which he firmly believed it was his duty to carry out unto death In doing so he was bound to give offence, and he did make enemies, and so must every man who is able to conceive a great purpose and possesses strength of will and energy of physique sufficient to carry it out. Had he been weakling enough to be swayed by the scruples of others he would never have left Cape Town No great work was ever yet accomplished without sacrifice, and we have here mainly to do with the work which Livingstone accomplished for science. That work is the highest of its kind, and had Livingstone been either a Byron or a Napoleon in character, the value of that work would not have been less. Fortunately it is clear from Dr Blaikie's pages—which consist largely of Livingstone's own journals and letters—what indeed was pretty clear before, that Livingstone was a pure and tender-hearted man, full of humanity and sympathy, simple-minded as a child, with a healthy ambition to do a great work for Africa and for science, and with energy and courage sufficient to carry it out The motto of his life was the advice he gave to some children he addressed in a humble Scotch meeting-house when he returned from his first great journey and found himself a great man—"Fear God and work hard"

SALVADORI'S ORNITHOLOGY OF NEW GUINEA

Ornitologia della Papuasia e delle Molucche di Tommaso Salvadori Parte prima 1 vol 4to 540 pp (Torino, 1880)

IN the second volume of the Linnean Society's *Journal of Proceedings*, published in 1858, will be found an article by Mr Sclater on the Birds of New Guinea, which gives in a few pages a summary of the then existing state of our acquaintance with this subject. The bulky quarto now before us, to be followed by three or four other similar volumes, is no bad evidence of the vast mass of additions that has been made to our knowledge of the Papuan avifauna since that period

In 1857 the only modern authorities on the birds of New Guinea were the naturalists of the French circumnavigating expeditions, who had explored the vicinity of Havre Dorey in the northern peninsula of the island, and the collectors for the Leyden Museum, who had visited Lobo Bay and other points on the south coast. Although much is still wanting to complete our knowledge of the Papuan avifauna, much has been done since those days In 1858 our famous countryman Mr. Wallace passed some months at Havre Dorey, and made excellent collections in every branch of zoology. Moreover in the neighbouring island of Batchian Mr. Wallace was fortunate enough to come across a new form of paradise bird—one of the few recent additions to this remarkable group—which was deservedly named after its discoverer, *Semioptera wallacii*. Mr Wallace was also the first of modern explorers to visit the Arroo Islands—which belong strictly to the same fauna as New Guinea, and in his well-known work on his "Travels in the Malay Archipelago" has given us a most interesting account of the habits of the paradise birds as there observed, and of the manner in which the natives procure their specimens

After Mr Wallace the Italian travellers D'Albertis and Beccari were the next to visit New Guinea, and succeeded in carrying their investigations further into the unknown interior than it had been hitherto believed possible to penetrate. The ascent of the Arfak Mountains was first accomplished by D'Albertis in 1872, and Beccari succeeded in making the same dangerous journey some years later, besides visiting many localities on the north coast which had not been previously explored Both these naturalists were active collectors of birds, and transmitted large collections to Europe. In 1875 and the following year D'Albertis turned his attention to the southern portion of New Guinea, and during his excursions up the Fly River made fresh additions to our knowledge of Papuan ornithology In the meantime a German naturalist, Dr A B. Meyer of Dresden, was engaged on new explorations on the shores of the great Bay of Geelvinck, and did not fail to make considerable additions to the rich avifauna of that district.

While Prof Salvadori has not neglected to consult every existing authority on Papuan ornithology, and, we believe, to visit every European museum which contains specimens from the Papuan region, it is mainly upon the large series accumulated by his countrymen D'Albertis and Beccari, to which must be added the numerous specimens obtained by the hunters of Heer A A. Bruijn of Ternate, that his present labour is based These collections, or at any rate all the important portions of them, have passed into the Museo Civico of Genoa, either through the liberality of the Marquis G Doria, the founder of that institution, or through assistance given by the Italian Government Their extent may be judged of from the fact, stated in the preface to the present volume, that they contained no less than 9539 specimens, which have thus come directly under Prof. Salvadori's observation, besides the examples examined in the Museums of Paris, London, Leyden, Bremen, Berlin, Dresden, and Vienna, which, as already stated, our author has visited for the purpose of preparing his work It is evident therefore that materials did not lack, and Prof. Salvadori's well-known abilities as an ornithologist give us every confidence that these materials will have been well used.

Such indeed is doubtless the fact If the succeeding volumes of the "Ornitologia della Papuasia" shall be executed in the same style as that in which the first volume has been prepared, there can be no question that a most important work will have been accomplished. Not only is every species fully and accurately described, but its complete synonymy is given, a detailed list of the specimens from various localities and remarks on their differences are added, and, in fine, every necessary particular is given that can contribute to a perfect history of the species. Would that other geographical works on ornithology were carried out with equal exactness and similar strict attention to details!

In conclusion we have only to express our thanks to

Prof. Salvadori for the admirable way in which he has commenced his laborious task, and to express our hope that he may bring it to a successful conclusion. In Mr Gould's great work on the "Birds of New Guinea" we have a series of magnificent illustrations of all the more remarkable forms of Papuan ornithology. Such a work as that of Prof Salvadori's was much wanted in order to perfect our knowledge of the history and literature of this attractive subject.

OUR BOOK SHELF

An Elementary Treatise on the Integral Calculus, containing Applications to Plane Curves and Surfaces, with numerous Examples. By B Williamson, F R S. (London Longmans, 1880)

OF a *third* edition we need only remark that it is a carefully revised issue of the second, and point out the few important additions that have been made In the discussion of Frullani's theorem (§ 119), a simple shape of the formulæ, due to Mr E. B Elliott, is given, and reference made to other articles on multiple definite integrals by the same gentleman (and by Mr Leudesdorf) in the *Educational Times* (1875) and in the *Proceedings* of the London Mathematical Society, 1876-7 A new article (119*a*) gives a proof of a simple character, by Zolotareff, of the remainder in Lagrange's series § 147 contains a remarkable extension of Holditch's theorem, due to Mr Elliott (*Mess of Math* February, 1878), and § 147*a* gives the "singularly elegant" theorem discussed by Mr. Kempe (*Mess. of Math* July, 1878), to which reference is made in Prof Minchin's letter in NATURE (December 23, 1880), in which he proves these theorems from other considerations. Various insertions of a minor character increase the volume by more than twenty pages A good feature of the present edition is an index at the end of the work

Botanisches Centralblatt Herausgegeben von Dr O Uhlworm Band 1, Quart. 1 4 (Cassel Fischer, 1880)

WE are now able to record the completion of the first volume of this valuable serial, a monument of extraordinary energy on the part of the editor and his band of assistant. The aim of the publication is to give an abstract or *résumé* of every important contribution to botanical science published in the scientific serials of the Continent of Europe, Great Britain, and America, and, as far as we have been able to judge, the undertaking has been carried out with great judgment and completeness Original works are also not neglected Appearing much more promptly than Just's "Jahrbucher," the "Centralblatt" is indispensable to any one who desires to keep abreast of any department of botanical science.

Botany for Children, an Illustrated Elementary Text-Book for Junior Classes and Young Children By the Rev. George Henslow, M A, F L S, &c (London, Edward Stanford, 1880)

WE do not think that botany can be taught with advantage to children from books. No method of teaching seems so well adapted to the wants of junior students as that of demonstration A flower pulled to pieces by the student and the parts and their importance intelligently explained by the teacher forms a lesson far more valuable than any to be got from a text-book With a few such demonstrations from easily-obtained flowers, taken as they present themselves, most of the elementary facts regarding flowering plants can be readily mastered, while the habits of observation and the facility of dissecting thus obtained are invaluable to the student. It is, we fear, too much the habit in teaching botany to make the student prepare a lesson from the text-book as if it were spelling or history This is really what should be most carefully avoided, although there must be a great temptation to proceed with the book lesson when the plant is not obtainable Mr Henslow states in his preface "The descriptions of flowers in this book are intended to form botanical reading-lessons, specimens of the flowers being at the same time placed in the hands of the pupils, who are required to dissect and examine them carefully, and be sure they see and understand each special part noticed in the text" When used in accordance with the directions laid down by the author, the book seems an excellent one, and calculated to serve its purpose well, although some very important types have been omitted for want of space. As we have known children to work out the structure of flowers for themselves by means of this little book and to enjoy the exercise, we believe the work will be deservedly popular The illustrations are rather coarse, but on the whole characteristic and often give details of structure sometimes omitted from much larger works

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts No notice is taken of anonymous communications*

The Editor urgently requests correspondents to keep their letters as short as possible The pressure on his space is so great that it is impossible otherwise to ensure the appearance even of communications containing interesting and novel facts.]

Geological Climates

I NOW proceed to justify my statement, which has caused Mr Wallace great surprise, viz —

"It is impossible to suggest any rearrangement of land and water which shall sensibly raise the temperature of the west of Europe, or sensibly depress the temperature of the east of North America"

It is proverbially difficult to prove a negative, and the only way to do so in this case is to show that any given redistribution of land and water is incapable of producing the effects ascribed to it

I have already shown that Mr. Gardner's proposed redistribution by means of a land connection between Greenland and Europe would fail to benefit the west of Europe In like manner I shall now demonstrate that Mr. Wallace's redistribution of land and water is quite inadequate to raise the temperature of the west of Europe.

Mr. Wallace's proposal is to introduce two new Gulf Streams into the Arctic Ocean, in addition to the present Gulf Stream

1 The first of these additional Gulf Streams would be the Kuro siwo, admitted through a widened Behring's Strait, the effect of which, he estimates, would be *to prevent altogether the formation of ice in the Arctic Sea*

2. The second additional Gulf Stream is provided by allowing the waters of the Bay of Bengal and of the Arabian Sea an outlet to the north through the Caspian depression into the Arctic Ocean The effect of this second Gulf Stream, he estimates, would be *to raise the temperature of the Polar ocean from 15° F to 20° F above the freezing point of water*

This mode of raising the temperature of the Arctic regions, so as to allow of the growth of their Miocene flora, occurred to me when speculating on the former high temperatures of these latitudes, but I rejected it as inadequate to account for the change of climate required for the following reasons But before giving these reasons I wish to add that Mr. Wallace has given two precise statements involving quantitative results, without giving the numerical grounds on which he made those statements.

The following are the grounds on which I deny the adequacy of Mr. Wallace's causes of change of climate —

(*a*) *Air and Water.*—Warm winds and cold winds are in themselves of little consequence in influencing climate, except they blow over a large expanse of warm or cold water, they are in fact only heat and cold carriers for the water. The specific heat of water is more than four times that of air, and water is 815 times heavier, bulk for bulk; therefore one cubic mile of water will contain as much heat as 3260 cubic miles of air at the same

temperature. From this it follows that the temperature of the air at the surface of the sea corresponds with the surface-temperature of the water. This has been fully confirmed by observations made in every latitude, which show that the difference of temperature between the air and sea is never more than one or two degrees Fahrenheit.

(*b*) *Gulf Stream.*—The temperature of the air above the Gulf Stream is:—

62° F.	at latitude 40°	45° F.	at latitude 60°
53 „	„ 50°	35 „	„ 70°

and the quantities of water contained in the Gulf Stream are:—

36 cubic miles per hour	at latitude 50°
36 „ „	„ 60°
24 „ „	„ 70°

The mean annual temperatures of the several latitudes, in the northern hemisphere, are, taken all round the globe—

29·3° F.	at latitude 60°	4·5° F.	at latitude 80°
14·4 „	„ 70°	0·0 „	„ 90°

From this it is evident that the Gulf Stream is inadequate to keep the temperature of the Polar cap, from the Pole to 60° lat., above the freezing point of water; so that if the heat and cold were uniformly distributed, the whole of this great area would be permanently frozen over, the thickness of the ice being greatest at the Pole, and least at lat. 60°.

This ideal ice cap (on the supposition of uniformly distributed heat and cold) represents accurately the amount of heat that must be introduced into the Arctic regions before their temperature rises to that of the freezing point of water. Its southern limit is lat. 58° 51′, where the mean annual temperature all round the globe is 32° F.

The thickness of this ideal ice cap at the Pole is unknown, but from what we know of the palæocrystic ice of Bank's Land and Grinnel Land must be measured by hundreds of feet; and its mean temperature must be at least 20° F. below the freezing point of water.

Mr. Wallace has put forward the supposition that the introduction of an equal proportion of the Kuro-siwo (to that of the Gulf Stream) would prevent the formation of sea-ice in the Arctic Sea. Before this could happen, the Kuro-siwo must first melt the ice-cap, and then keep it from freezing again.

To show how inadequate this supposition is, I shall calculate what the Gulf Stream has already done, and then show what the Kuro-siwo could do.

Let us suppose that the whole heat of the Gulf Stream, passing northwards through the parallel of 70° N., is employed in melting a supplementary ice-cap extending from the Pole to 70° N. and that this supplementary ice-cap is at the temperature of 32° F. only (*mere ice-sludge*); I find the thickness of ice melted is only 5·874 feet[1] yearly.

If therefore the Gulf Stream were cut off by a barrier at 70° N. lat. an additional growth of ice at 32° F. less than 6 feet thick might grow upon the area from the Pole to 70° N. lat.

Of course the Gulf Stream expends its heat in melting local ice in the Spitzbergen and Barentz Seas, and perhaps still further east in summer along the Siberian coast, and not in melting the supplemental ice-cap I have imagined; nevertheless the whole work done by it does not exceed the melting of the ice cap from the Pole to 70° lat., and of a uniform thickness of 5·874 feet. In other words, the work done by the Gulf Stream north of 70° lat. is equivalent to the melting of 4382 cubic miles of ice at 32° F., which represents a definite quantity of heat. It is however much easier to conceive the ice-cap from the Pole to 70° lat., of 5·874 feet thick, than 4382 cubic miles of ice.

As the ice melted between the Pole and 70° lat. has a temperature of 6° F., instead of 32° F., it is easy to see that the thickness of ice-cap melted by the Gulf Stream is 4·813 feet instead of 5·874 feet.

(*c*) *The Kuro-siwo admitted through Behring's Strait.*—Mr. Wallace quotes me as stating that the volume of the Kuro-siwo is 2½ times the volume of the Gulf Stream: I believe it to be so, but in the present discussion shall consider it to be only twice as great; for at least one-fifth of it obtains partial entrance into Behring's Strait, and behaves like the Gulf Stream; as appears from the lesser rigour of the climate of the Parry Islands, from the open water discovered by Collinson along the northern coast of America, and from the return cold current of the coast of China.

From the calculations I have just given it appears that the Kuro-siwo current admitted through a widened Behring's Strait would be competent to melt a thickness of ice-cap extending from the Pole to 70° lat., amounting to 9·626 feet.

I shall leave your readers to judge whether this amount of ice melting justifies Mr. Wallace in asking "Suppose that only an equal proportion (to that of the Gulf Stream) of the Kuro-siwo entered the Arctic Ocean, is it not probable that no sea-ice at all would form there?"

To me this question appears like a proposal to Hercules to clean out the Augean stables with a teaspoon.

(*d*) Let us now add on the *Mozambique Current*, converted into a *Caspian depression Gulf Stream*. Of this current I cannot allow Mr. Wallace to appropriate more than half, unless he shows cause for a land barrier preventing the other half from continuing its present course into the southern hemisphere, there to aid in mitigating the climates of the Temperate and Antarctic zones.

The *Caspian Gulf Stream* will then cut off another slice of 3·609 feet in thickness from the ice-cap extending to 70° lat. Is this amount of ice melting sufficient to perform the feat assigned to it by Mr. Wallace of "raising the former [the Polar sea] to perhaps 15° or 20° F. above the freezing point"?

(*e*) If there be any truth at all in the power of Gulf Streams to modify the climates of the Temperate and Polar zones, the southern hemisphere should be warmer than the northern hemisphere, as it receives three Gulf Streams instead of 1½ Gulf Streams (without discussing their relative volumes).

This is the actual fact, as is easily proved, notwithstanding the iterated parrot-like statements to the contrary copied from text-book to text book.

I have shown that, taking the annual mean temperature at all longitudes, the cold of the northern hemisphere is represented by an ideal ice-cap which is thickest at the north pole and terminates in the latitude 58° 51′ N., where the mean annual temperature is 32° F.

In the southern hemisphere, the latitude at which the mean annual temperature for all longitudes is 32° F., is found at 62° 41′ S. This limit of the ideal southern ice-cap (measuring the Antarctic amount of cold) lies nearer to the South Pole by 3° 50′, or 230 geographical miles, than the corresponding limit of the northern ice-cap from the North Pole.

These limits of ideal ice-cap at the North and South Poles are independent of the wholly different question as to which of the Poles has the largest volume of ice surrounding it, into which I shall not enter at present.

(*f*) From what I have proved above it is evident that the two return compensating currents from the Arctic seas will still consist of ice-cold water, one of which, on the coast of Asia, of double the volume of the Labrador current, will reduce the climate of China and Northern Japan to a condition compared with which the present climate of Hudson's Bay would be a Garden of Eden; and the other would bring the Ural range and Eastern Europe into the present condition of Labrador. I think it is evident, under these latter conditions, that Bournemouth would suffer, and not gain, by Mr. Wallace's arrangements of land and water. The services rendered to the Arctic lands by the two new Gulf Streams would, in my opinion, be dearly purchased by the damage done by their compensating currents in the sub-tropical latitudes of Eastern Asia and Eastern Europe.

SAML. HAUGHTON

Trinity College, Dublin, December 31, 1880

IN NATURE, vol. xxiii. p. 169, Mr. Ingram mentions the growth of *Bambusa metaké* in Leicestershire. I have found large varieties of bamboo cultivated on a great scale in Northern Nippon, where the winter temperature is certainly much colder than in England. The northernmost place where I found them was the vicinity of Yokobori, about 39° 12′ N., at a small distance (twenty-five miles) from the west coast. The nearest place to the south where observations were made is Niigata, 37° 55′, and to the north Hakodate, 41° 46′. The coldest month has a temperature respectively of 33°·0 and 27°·3 F. Yusawa being situated about 450 feet high, and in the interior, the coldest month there must have not over 30°, and a heavy snowfall is the rule every winter. Again, on descending the dividing ridge

[1] I assume the following data:—Area from Pole to 70° lat. = 4,476,200 sq. geo. m.; latent heat of ice cold water = 142° F.; Gulf Stream = 24 cub. miles per hour; temperature = 35°·6 F.

between Jukussina and Yonesawa, I first found large bamboo plantations near the last place, about 1000 feet above sea-level, and 37° 55′ N. Between here and Niigata the temperature of the coldest month must differ by about 3°, the latter place being situated near the sea. This gives about 30° F. for Yonesawa, or about the same as at Yusawa. Now in Great Britain, the mountainous districts excepted, the mean temperature of the coldest month is nowhere lower than 36°. A. WOEIKOF

St. Petersburg, December 19, 1880

IN my letter (vol. xxiii. p. 194) I inadvertently stated that Sequoia cones were composed of from 16 to 20 scales. I intended to say 16 to 50, which appears to be the maximum number in either of the existing species. J. S. G.

Chalk

THE objections urged by Mr. S. N. Carvalho, jun. (vol. xxiii. p. 194), to Wallace's explanation of the deposition of chalk must have occurred to every geological reader of "Island Life." There are very many other objections to it, and I trust to be permitted to call attention to them in the *Geological Magazine*, as they are probably too purely geological to interest the readers of NATURE.

J. S. G.

Average Height of Barometer in London

IT was stated in your "Meteorological Notes" a week or two ago in regard to the paper by Mr. H. S. Eaton on the average height of the barometer in London, that "the series is sufficiently extended as to entitle it to be considered one of the most valuable we possess in dealing with questions of secular meteorological variation."

Regarding it in the same light I have thought it worth while to apply Mr. Meldrum's method for discovering the existence and character of the secular variation in the sun-spot cycle. Taking the period 1811–79 I find the following figures for the mean cycles:—

LONDON

Annual Barometric Abnormals, Mean Cycles

	Maximum years in fifth line		Maximum years in seventh line	
	Pressure (1811–77)	Sun-spots (1811–77)	Pressure (1816–79)	Sun-spots (1816–72)
1.	+0·006	−33·9	−0·005	+23·3
2.	+ ·016	−23·4	− ·001	+14·5
3.	+ ·013	0·0	− ·001	+ 4·8
4.	− ·002	+28·2	− ·003	− 5·6
5.	− ·010	+43·1	− ·005	−19·0
6.	− ·011	+34·2	·001	−32·5
7.	− ·007	+16·8	± ·000	−37·1
8.	+ ·001	+ 0·2	+ ·011	−25·4
9.	± ·000	−14·2	+ ·021	+ 1·8
10.	+ ·001	−24·2	+ ·010	+30·9
11.	± ·000	−26·3	− ·003	+44·8

The variation of pressure, though not so regular as that I worked out for St. Petersburg in 1879, is of an almost exactly opposite character, the minimum pressure appearing as in India, about the time of maximum sun-spot, and the maximum pressure lagging two years behind the epoch of minimum sun-spot. These results agree with the known annual rainfall variation in the same cycle, which is likewise similar in character to that which occurs in the tropics. I would suggest that the marked difference between the results for London and St. Petersburg possibly arises from the close communication between England and the tropics through the medium of Atlantic oceanic and atmospheric currents. E. DOUGLAS ARCHIBALD

Experiments with Vacuum Tubes

IN my letter published in the last number of NATURE I omitted to say that we have compared vacuum tubes without electrodes with a tube containing water. A tube was filled about nine-tenths full of water and then sealed hermetically. It was then applied to the prime conductor of the electric machine and electrified in the same way as the vacuum tubes without electrodes, and it was found to behave precisely as they did. The water tube became charged as a double Leyden jar, positive outside and negative inside at the end next the prime conductor, and negative outside and positive inside at the other end. A great tendency to rupture of the glass was also observed. So far as we have been able to see the most perfect vacuum that I have been able to obtain with the Sprengel pump has behaved as to frictional electricity precisely as a perfect conductor such as water.

These experiments seem interesting in connection with the discoveries of Mr. Crookes as to the properties of a very perfect vacuum. No doubt it was known that flashes can be obtained within vacuum tubes without electrodes; but the properties of a perfect vacuum as a conductor of electricity has not been hitherto sufficiently investigated. J. T. BOTTOMLEY

Physical Laboratory, the University, Glasgow, January 8

Oxidation of Quinine, &c.

IN the Chemical Society's *Journal* for December, 1880, there is an abstract of a paper by Hoogewerf and Van Dorp, published in *Liebig's Annalen*, cciv. 84–118, in which the authors describe experiments on the oxidation of quinine, quinidine, cinchonine, and cinchonidine. As reference is made in this paper to our work upon the same subject in such a manner as to lead to the inference that we had copied Hoogewerf and Van Dorp, we beg to call attention to the dates of publication of the various memoirs relating to the matter.

In the Berlin *Berichte*, x. 1936 (close of 1877), Hoogewerf and Van Dorp published a preliminary note on the oxidation of aniline, toluidine, and quinine, and stated that they had obtained amongst other products of oxidation of quinine a nitrogenous acid, to which apparently they attached little importance. Of this acid they gave no further account. At that time we were working at the same subject, and had come to some important conclusions.

As Hoogewerf and Van Dorp's results contained nothing relating to quinine in addition to what had been observed by Cloez and Guignet many years previously, we did not consider that they were entitled to claim that this field of work should be reserved for them. We therefore sent our paper to the Chemical Society, before which it was read on January 10, 1878 (see also Berlin *Berichte*, xi. 324). In this paper we stated that the acid obtained by us from quinine was probably identical with dicarbopyridenic acid. That the acid was a pyridenic acid we had no doubt, but owing to the difficulty of purification we had not been able to establish its formula with certainty.

In the Berlin *Berichte*, xii. 158–161, was published a second paper by Hoogewerf and Van Dorp (read before the Berlin Chemical Society on January 27, 1879), on the acid obtained from quinine, giving no analyses, but stating that the acid was *tri-* and not *di*carbopyridenic acid, thus confirming our result in its important bearing, viz. the connection between the quinine and pyridine series. In the same paper they suggested that an acid obtained by them from quinidine and cinchonine was identical with the quinine acid.

Immediately on receipt of the number of the Berlin *Berichte* containing Hoogewerf and Van Dorp's paper, we forwarded to the secretary of the Chemical Society our second memoir, which contained numerous analyses of the acid obtained, not from quinine only, but also from the allied alkaloids, quinidine, cinchonine, and cinchonidine, together with a full description and analysis of all its important salts. That paper was read before the Society on February 20, 1879.

In *Liebig's Annalen*, cciv. 84–118 (July 31, 1880), or a year and a half after the publication of our second paper, Hoogewerf and Van Dorp published analyses of the acid and many of its salts, prepared from three alkaloids, the results confirming our own in all points.

Our claim, which the above dates fully substantiate, is to have been the first to establish the connection between the quinine and pyridine series, and to have proved that the four alkaloids all gave the same oxidation product.

Prof. Butlerow of St. Petersburg, immediately on appearance of our first paper, when engaging in work closely connected with, but not overlapping ours, wrote suggesting that we should

each confine himself to his own branch, at the same time recognising the importance of our discovery; and Herr Konig, in a paper published in the *Berichte*, xii 97, referring to our first paper, says: "Es ist der erste glatte Uebergang der Chinaalkaloide in eine jedenfalls einfachere Substanz—das Pyridin."

The Temperature of the Breath

DR. DUDGEON'S first letter under this heading contained the suggestion of a friend that his enigmatical thermometric readings were to be accounted for by the high temperature "caused by the condensation of the moisture of the breath by the silk handkerchief." The discussion that followed has not only brought us back to this solution, but has also furnished us with an authoritative expression of opinion that the clinical thermometer is not sensitive to pressure. F. J. M. P. first hinted the contrary proposition only to have it thrust aside by Dr. Dudgeon with blunt denial, neglected by Dr. Roberts, and finally discarded by himself for no other apparent reason than that aqueous vapour in condensing liberates heat. Yet I venture to assert that readings as high as any obtainable by Dr. Dudgeon's method, less the pressure, can be obtained by a very similar mode of experimenting, without the developed heat. 1. If the bulb of a thermometer, protected by paper or other non-conductor, be squeezed in an intermittent manner between finger and thumb, it will be found that the mercury can readily be made to dance up and down through about a degree on the scale with a celerity not attributable to changes of temperature. 2. If eighteen inches of cotton thread be tightly wound about the bulb, on immersing the thermometer in water it will exaggerate the temperature sometimes by as many as 12° F. 3. If a tube filled with cacao butter be substituted for the thermometer the butter beneath the thread will be longer in melting than that in other portions of the tube, a result which I think proves that the high readings of experiment No. 2 are not temperature, but (in the light of No. 1) pressure readings.

My chief object in writing is to protest on general grounds against the treatment accorded to F. J. M. P.'s suggestion, but at the same time I wish to express my opinion that Dr. Roberts' argument would have been strengthened by giving heed to it, for I see nothing in *his account* of the interrupted experiment not explainable on the pressure hypothesis alone, the descending series of readings being perchance due to a yielding of the wrappings under prolonged tension. On the other hand I have to thank this omission on Dr. Roberts' part for having induced me to test the subject for myself, and thus experience, in repeating his experiment, the rare pleasure of scientific surprise at seeing the index mount higher and higher above the level of my expectations under conditions which left no doubt as to the cause being a rise of temperature. Dr. Dudgeon has done good service by directing attention to a simple experiment which, properly interpreted, throws new light on the philosophy of clothes, and should prove a telling shaft in the quiver of popular science.

WM. MCLAURIN

Islington, December 26, 1880

IN the number of NATURE which reached Madras after the departure of the mail conveying my letter of the 9th inst., I was glad to read Dr. W. Roberts' abundantly full and lucid explanation of the heat produced by breathing on thermometers enveloped in hygroscopic substances. He has, by a very simple method, confirmed the view endorsed in my communication in NATURE, vol. xxiii. p. 534.

That the effects of friction and of compression of air are so slight that they may be disregarded, has been proved; and the rise has been clearly traced to absorption of aqueous vapour. It has yet to be determined how much of this heat may be accounted for by the reduction of aqueous vapour to the fluid state, and how much by capillary action and absorption of water, with or without chemical union, and its reduction to the solid state—all of which may be included in hygroscopic action. This determination would involve some intricate investigations which some scientific specialist may perhaps find leisure to undertake. That more than simple vapour condensation is concerned in the production of hygroscopic heat is shown by the rise of temperature on adding water to a non-saturated hygroscopic substance.

A scientific colleague has suggested to me that some cases of very high axillary temperatures may be explained by the clothing of patients being pressed into the axilla in contact with the thermometer. Thus, by folding a banian round a thermometer placed in the axilla, I registered a temperature above 100° F., while the temperature in the bare axilla was 98.3. It is evident that recently changed and dried clothing and clothing warmed by the body of a non-perspiring fever patient would have still more effect when pressed closely into a hot and moist axilla. Although this point is important mainly to physicians, I venture to draw attention to it through your columns on account of its connection with the subject of hygroscopic heat.

C. J. MCNALLY

Madras, December 16, 1880

Distance of Clouds

I HAVE conveniently determined the distance of passing clouds by a method probably not new, but which I have not seen described.

It consists in ascertaining the velocity with which the shadow of a cloud traverses level ground, which is easily observed, and of course gives the velocity of the cloud itself.

The angular motion per second of clouds passing overhead is simultaneously observed by means of a coarse micrometer in a telescope, or with a theodolite.

The distance is thus obtained with fair approximation.

$$\text{Distance} = \frac{v\,t\,3438}{n},$$ v being the velocity in feet per second, and n the number of minutes of arc described in t seconds.

A distant mirror may be advantageously used in determining the velocity of the shadow.

EDWIN CLARK

Fluke in Calves

CAN any of your readers account for the following facts?—An examination of the liver of some six-weeks-old calves which had never touched any food but their mother's milk showed them to be infested with fully-developed Fluke (*Distoma hepatica*). It is clear that the presence of these flukes does not admit of the usual explanation, viz., the ingestion with green food or water of mollusca bearing the larva in one of its earlier stages.

I should be grateful if any of your readers could suggest an explanation of the mode in which the fluke entered the liver of the calf. Is it possible that the larva may have passed into the milk of the mother, and so have entered the stomach of the calf?

It may interest some of your readers to know that traces of fluke were present in the livers of cattle lately killed when in high condition. The fluke had apparently been established in the liver some considerable time previous to the slaughter of the animals, and had perished on their attaining to a state of high health and vigour.

A. B.

JOHN STENHOUSE, LL.D., F.R.S.

IN the early morning of the last day of the old year we lost one of the few surviving founders of the Chemical Society, Dr. John Stenhouse. He was born at Glasgow, October 21, 1809, the son of William Stenhouse of the well-known firm of calico-printers, John Stenhouse and Co. of Barrhead. He was educated first at the Grammar School and then at the University of Glasgow, and long resided in his native city. At an early age he turned his attention to chemistry, and diligently studied that science under Graham and Thomson, and subsequently with Liebig at the University of Giessen. When he removed to London, after the failure of the Western Bank of Scotland had deprived him of the fortune bequeathed to him by his father, he became Lecturer on Chemistry in St. Bartholomew's Hospital, London, but was obliged to resign that appointment in 1857 owing to a severe attack of paralysis. Even this affliction however did not discourage him, and after the lapse of a short time he renewed his scientific labours. In 1865 he succeeded Dr.

Hofmann as non-resident Assayer to the Royal Mint, but was deprived of the appointment by Mr. R Lowe, who abolished the office in 1870.

A pupil of Graham and Liebig, he had all their enthusiasm for scientific investigation, and devoted nearly the whole of his time to research work in the domain of organic chemistry the eminence he attained in this branch of science is fully recognised, but his contributions to our technical knowledge are not so well known He was the author of many ingenious and useful inventions in relation to dyeing, sugar manufacture, tanning, &c, but the greatest and most permanent has been the application of charcoal for disinfecting and deodorising purposes, which took the form of charcoal air-filters for the ventilation of sewers, and the charcoal respirator, the best of all respirators, not only for preventing the deleterious effects of noxious gases in numerous manufacturing operations, but also for the protection of those subject to bronchitis, asthma, and other similar diseases

It is impossible in our limited space to give even an outline of the numerous investigations which he published during his long scientific career, extending as it did over a space of more than forty years The results are embodied in about 100 papers, published in various scientific journals, English and foreign; they relate in great part to what may truly be called "organic chemistry"—the chemistry of carbon compounds formed by organised bodies John Stenhouse was LL.D of Aberdeen, a Fellow of the Royal Society, which awarded him the Royal Medal in 1871, one of the founders of the Chemical Society, and a Fellow of the recently-established Institute of Chemistry Of his personal character those who knew him intimately could never speak too highly, his death will be felt and mourned not only by his many personal friends, but also by men of science throughout Europe.

WILHELM HEINTZ

WE recently recorded the death, at Halle, on December 1, of Prof. W Heintz, one of the leading German chemists of our day He was born at Berlin, November 4, 1817. His earlier university studies were undertaken with a view of becoming a pharmacist, but this intention was relinquished as the attractions of a more purely scientific career were offered to him In 1844 he received the doctor's degree at the Berlin University, and two years later he was admitted as privat-docent in the philosophical faculty of the same university In 1850 he accepted a call to Halle as the successor of the well-known Marschand; and here, after passing five years as an extraordinary professor, he was appointed in 1855 to the full professorship of chemistry, and the directorship of the newly-built laboratory, posts which he occupied at the time of his death

As a teacher and as a guide to students inclined towards chemical research, Prof. Heintz evinced more than ordinary capacity, and for a quarter of a century he has ably maintained the reputation of Halle among the centres of chemical interest in Germany. This reputation is due in no small part to his own personal contributions as an investigator, for few chemists of our day have manifested such unwearied energy and long-continued application, such thoroughness of work, accuracy of observation, and widespread familiarity with fact and theory as are evinced in Heintz's manifold and diversified researches.

The earlier portion of his career was directed to the solution of problems in physiological chemistry. Among his more important researches in this direction mention should be made of those on the juice of the *Galactodendron* (1845), on kreatin and kreatinin (1847), on lactic acid in the gastric juice (1849), on the composition of bones, and on cholesterin (1850), on the colouring matter of gall stones (1851), on urinary sediments (1862), and more especially on the animal and vegetable fats. This latter research, extending over a period of about seven years, includes exhaustive studies on the physical properties of the fats, methods of their separation, their chemical constitution and nature, the products of their decomposition, &c His careful observations of the melting points and composition of the fatty acids in the pure state and when mixed with each other, form essentially the basis of our present knowledge on this subject, and enabled him at the time to show the composite character of various fats which preceding chemists had regarded as pure compounds

In analytical chemistry Heintz devised a variety of methods and modifications of methods, amongst which mention may be made of his contributions on the estimation of sulphur in organic bodies, on the separation of magnesia from the alkalies, on the analysis of ashes (1847), on the determination of urea and uric acid, on the detection of gall (1848), on the determination of nitrogen (1851), on the estimation of phosphoric acid, and numerous analytical data

In inorganic chemistry his researches were chiefly confined to studies on a variety of phosphates, on bismuth and uranium salts, on the preparation of cæsium and rubidium compounds (1865), on the combustion of ammonia in oxygen (1864), on the silicates of the alkaline metals, and to the examination of the minerals margarite, stassfurtite, carnallite, aluminite, and boracite, the latter of which he prepared artificially (1860)

It is however in the field of pure organic chemistry that Heintz's discoveries have been most numerous and important They commence with his investigation on saccharic acid, begun in 1844 and resumed in 1858-1860, to which we owe a great measure of our knowledge of this acid, and especially of its salts and ethers This was followed in 1856 by a study on the action of chloride of sulphur on the salts of organic acids, in which he recorded the unvarying and simultaneous formation of chlorides and sulphates at the expense of the organic salts In 1859 he began his extensive research on glycollic acid, which occupied much of his time until 1872, by exposing monochloracetic acid to the action of various sodium alcoholates, obtaining thereby the different ethers of glycollic acid, thus with sodium ethylate

$$CH_2Cl\ COOH + NaOC_2H_5 = NaCl + \begin{array}{l} CH_2\ OC_2H_5 \\ | \\ COOH \end{array}.$$

By means of this prolific reaction he obtained a number of interesting derivatives of the acid in question Closely allied to them were the acid ethers of glycollic acid, obtained by submitting monochloracetic ethers to the action of salts, or by acting upon glycollic ethers with such bodies as phosgene or chlorocarbonic ether Among the other important compounds discovered by him in this group are glycolamide, glycol-ethyl-amide, diglycollic acid—$O(CH_2\ COOH)_2$ obtained by the action of sodium hydrate on monochloracetic acid, diglycoll-diamide, diglycollamic acid, &c During this same period he made noteworthy investigations on the ethyl-amines, on sulphocyan-acetic acid and its derivatives, on nitrate of ethyl, on ethyl-hydantoin, on lactic acids, and on the amido-acids obtained from chloropropionic and iodopropionic acids by the action of ammonia With 1874 commences his last important research—that on the aceton bases, the simplest of which result from the action of ammonia on aceton While forced to overcome manifold difficulties in the prosecution of this investigation, Heintz succeeded in isolating a number of novel and important compounds, especially interesting from a theoretical point of view The leading forms embraced in this new group are diacetonamine, triacetonamine, the corresponding alcohol bases diaceton-alcamine and

triaceton-alcamine, benzal-diacetonamine, amido-trimethyl-oxybutyro-nitrile resulting from the action of prussic acid on diacetonamine, and amido-dimethyl-acetic acid, obtained by the oxidation of diacetonamine; while a paper published a few months since describes a new aceton base containing sulphur. Prof. Heintz's activity was manifested up to within a few months of his death In addition to the paper just alluded to his contributions to chemical literature during the year just closed include articles on triaceton-diamine, on the existence of acetonine, on two compounds of urea with chloride of gold, and on diethidene lactamic acid.

Prof Heintz was the recipient in 1862 of the honorary degree of M D. from the University of Konigsberg in recognition of his services to physiological chemistry In 1876 he was elected an honorary member of the London Chemical Society T H. N.

SMOKE ABATEMENT

A MEETING was held in the Egyptian Hall at the Mansion House on Friday last, under the presidency of the Lord Mayor, to consider the best means of remedying the evils arising from the present smoky condition of the atmosphere of London Among those present were Mr G J Shaw-Lefevre, M P (First Commissioner of Works), Mr W Spottiswoode (President of the Royal Society), Dean Stanley, Sir U. Kay-Shuttleworth, Dr Farquharson, M P, Mr Ernest Hart (Chairman of the joint committee of the Health and Kyrle Societies), Col Festing, R E, Dr. Alfred Carpenter, and Prof. Chandler Roberts

Mr Ernest Hart, in explaining the objects of this movement, said that some practical advance had already been made It was not pretended that fogs could be prevented, but since smoke added opaqueness and corrosive and other deleterious qualities to London fogs, much might be done to diminish the discomforts and evils we suffered from this cause Having described the objects proposed to be attained by an exhibition of apparatus and smokeless fuel, he gave the results of some calculations in order to bring home to the minds of his hearers the enormous waste of money involved in the present arrangements for heating houses

Mr Spottiswoode stated that a committee of the Royal Society had been appointed to investigate the facts connected with the formation of fog, but while we looked to science to tell us what was wanted to improve our atmosphere, we looked to the legislature to carry out those effectual preventive measures which all hoped would some day or other be devised Nevertheless, without the strenuous aid and co-operation of every householder the best legislation could be turned to but little account In conclusion he moved, "That it is the opinion of this meeting that the smoky condition of the atmosphere of London injuriously affects the health and happiness of the community, besides destroying public buildings, deteriorating perishable fabrics, and entailing in various ways unnecessary expenditure"

Sir Frederick Pollock seconded the resolution, and urged that much might be done if every one who had an old fire-grate to replace would provide one of an approved and really more economical pattern.

Mr. G J Shaw Lefevre moved, "That this meeting is further of opinion that the injurious effects of fog are largely due to the quantities of smoke given forth from the chimneys of furnaces, manufactories, and steam-vessels, as well as dwelling-houses, and that the smoke in the metropolis might, without any considerable difficulty, be greatly lessened by the better enforcement of the existing law, by the introduction of amended legislation, and by the general use in all descriptions of premises, including dwelling-places, of proper smoke-preventing apparatus, improved household stoves and grates, or of smokeless fuel" As the head of the public department responsible for the public works of this great metropolis, he need hardly assure those present that he was deeply impressed with the importance of the subject under discussion. The importance of pure water was often insisted upon, but surely pure air was even more important Yet, for years past, it must be admitted that the air of London had been getting worse, and fogs were denser and of longer duration than formerly, even invading the summer months There could be no doubt that forty or fifty years ago London was famous for its roses, now it was impossible to get the rose to blossom here, and it was all but impossible to get any of the conifers to grow in the darkness of the London atmosphere He should, however, deprecate any hasty attempts to legislate Much might be done by the extension of the existing Acts relating to the abatement of the nuisance from smoke, and he thought Government might be rightly called upon to give some additional facilities for the purpose of enforcing those Acts It was monstrous that in these days so many factories should not be consuming their own smoke, and, since there was a great economy in the use of appliances which prevented this waste of fuel, there was no hardship in enforcing the Act When they came to the question of the domestic consumption, he thought it would not be wise to attempt to interfere by any legislation They must rather trust to persuasion and example and inducements His own hope was in the introduction of some other heat-giving apparatus Doubtless the substitution of anthracite for north-country coal would be an advantage; but he did not see the means of persuading the enormous mass of householders to use the smokeless coal unless it could be distinctly proved to them that there would be economy in the change. He would suggest that it might be worth while for the gas companies to turn their attention to the production of gas for heating purposes He could not help thinking that the time was not very far distant when not only our streets and public buildings, but also our private houses, would be lighted by electricity There were non-luminous gases suitable for heating purposes, which might be made at a much less cost than the gas at present supplied for lighting. From a friend he had learnt that water-gas, which could be made at a low rate, was used in many towns in America for heating purposes. Every one could do something to help forward this good work of abating smoke, and for himself he would promise to use his efforts in the department with which he was connected to diminish the nuisance from smoke. When he mentioned that some 20,000 tons of coal were purchased annually by the department, the meeting would appreciate the extent to which the public offices added to the smoke in the atmosphere of the metropolis. He hoped the time would not be far distant when they would have restored the atmosphere of London to its early purity, the blossom to our London roses, and the bloom to the cheeks of our London children

Dr Alfred Carpenter urged that this was a question particularly affecting the middle class and the poor, the waste of fuel at present being deplorable. He moved "That this meeting approves the proposal of the joint Committee of the National Health and Kyrle Societies to hold an exhibition, by permission of Her Majesty's Commissioners for the Exhibition of 1851 and the other authorities, in buildings erected for the International Exhibition of 1862, of the various smokeless coals and other fuels, and of various appliances applicable to household and manufacturing purposes for the reduction of smoke, and to test the same, in order to demonstrate for public information the means practically available to secure that object This meeting is of opinion that the investigation and testing should precede any application for amendment of the existing Smoke Acts, or for new legislation in regard to smoke from dwelling-houses."

THE INDO-CHINESE AND OCEANIC RACES—TYPES AND AFFINITIES[1]

III.

IN the accompanying series of illustrations the late King of Camboja (Fig 14) and the Stieng of the forest region east of the Me-Khong, between 12°–13° N. lat (Fig. 15), may be compared, on the one hand, with the famous statue of the leprous king, Bua-Sivisi Miwong (Fig. 16), the traditional builder of the temple of Ongkor-Vâht, and on the other with the first King of Siam and his late Queen (Figs. 17 and 18). Here the resemblance of Figs 14, 15, 16 to the European type and difference from the Mongoloid Siamese (17 and 18) is too obvious to need further comment. For these illustrations from Mouhot's "Travels in Siam, &c ," I am indebted to the courtesy of the publishers, Messrs Murray, Albemarle Street

The Caucasian element in Indo-China differs from the Mongoloid quite as much in speech as it does in other respects. Here the Mongol races, as already stated, all speak monosyllabic toned languages , but the Cambojans and kindred peoples all speak polysyllabic untoned languages, a fact scarcely yet recognised even by the best-informed philologists Taking the Khmêr as the typical language of this group, it will be convenient here to establish its polysyllabic character, reserving the question of its true affinities till we come to the allied races of Malaysia and Polynesia. The so-called monosyllabic or isolating family of languages—Chinese, Tibetan, Annamese, Siamese, Laos, Khasia, Shan, Burmese, Khyeng, Karen, Talaing, Kuki, and most of the innumerable Himalayan dialects—must all be regarded as at present reduced to a state of profound phonetic decay Whether originally they were all essentially monosyllabic, possessing, like the Aryan, roots of one syllable only, it is very difficult to say , but it seems certain that they were not originally toned In fact there can be no reasonable doubt that the tones are a later development, worked out unconsciously to preserve distinctions between words that had assumed the same form by loss of initial or final letters Thus in Chinese the final letters *m, k, t, p* have disappeared in the correct Mandarin dialect, causing roots like *kom, kok, kot, kop* all to assume the form of *ko*, toned four different ways according to the sense

This principle, which, combined with the absence of inflection or root modification, constitutes the very essence of the monosyllabic system, pervades the whole family. But it is absolutely unknown in the Khmêr group, in which words, whether monosyllables or polysyllables, are always uttered without intonation, as in all other languages. Its polysyllabic character was not recognised by Francis Garnier, but it has been abundantly demonstrated by Bouillevaux and Aymonnier, and will be made evident further on But because the Cambojans are of Caucasian, and their speech of polysyllabic, type, it does not follow that the Cambojan must be an Aryan language As already pointed out, within the Caucasian ethnical, there are several fundamentally distinct linguistic groups, which are now past reconciliation. To attempt to affiliate Cambojan with Sanskrit must necessarily end in failure, as did Bopp's attempt to include the "Malayo-Polynesian" in the Aryan family It must always be remembered that man is at least a quaternary, if not a tertiary animal, consequently that human speech is probably several hundred thousand years old. This period has been too short to evolve more than perhaps three or four really distinct physical types, but it has been long enough to evolve perhaps hundreds of really distinct linguistic types, many now extinct, some lingering on in contracted areas and remote corners, several, like the Sorb of Lusatia and the Pyrenean Basque, actually dying out, some few, like the Chinese, Russian, Spanish, and especially English, absorbing most of the rest, and threatening to divide the world between them.

[1] Continued from p 224

B —CAUCASIAN TYPE—(*Continued*)

V. OCEANIC BRANCH. *Indonesian and Sawaiori, or Eastern Polynesian Groups*

All the Oceanic peoples, other than the dark races of Class A, are commonly grouped together under the collective term "Malayo-Polynesian." By this name are consequently understood all the yellow, brown, or olive-brown inhabitants of Malaysia and the Indian and Pacific Oceans, that is to say, all varieties of Malays in Malacca and the Dutch East Indies, the Malagasy of Madagascar, the Philippine Islanders, the Micronesians, the natives of Formosa and the large brown Eastern Polynesians. The expression was originally proposed by William von Humboldt, merely in a linguistic sense, to designate the group of fundamentally connected languages, which really prevail amongst all these widely diffused peoples. But, like Aryan and so many other similar terms, it gradually acquired an ethnical meaning, and most ethnologists now take it for granted that there is a Malayo-Polynesian race, as there is a Malayo-Polynesian speech But such is not the case, and as on the mainland, so in the Oceanic area, the presence of the two distinct Caucasian and Mongolian types must be recognised and carefully distinguished It seems hopeless to do this as long as the misguiding expression Malayo-Polynesian continues to figure in scientific writings While retaining Malay for the typical olive-brown Mongolian element in the Eastern Archipelago, I have elsewhere proposed *Indo-Pacific* for the brown Caucasian element in the Indian and Pacific Oceans, and *Sawaiori* for the large brown Polynesians, constituting the eastern and most important branch of that element

It has already been remarked that the Caucasians are the true autochthones of Indo-China They seem to have also preceded the Mongol migration to the Archipelago, no doubt driven thither by the continual pressure of the Mongols advancing southwards and eastwards from High Asia. In the Archipelago they occupied chiefly the large islands of Sumatra, Borneo, Gilolo, and Celêbes, here probably exterminating the aboriginal Negrito tribes But here also they were followed by the Mongols from the mainland, with whom some amalgamated, producing the present mixed races of Western Malaysia, while others migrated eastwards to their present homes in the Eastern Pacific Here they occupy almost exclusively all the islands east of a line running from Hawaii through Samoa to New Zealand, those groups included West of that line they are found mostly blended with the Melanesians, as explained in Section II , but also in a pure state at a few isolated spots such as the Ellice and Phœnix Islands, Rotuma and Uvea in the Loyalty group They are also found blended with the Malay and other elements in Micronesia

That this large brown race reached the Pacific from the west there can be no reasonable doubt, and this view is now consequently held by Hale, Flower, Whitmee, de Quatrefages, and most recent ethnologists I Muller and de Quatrefages have even identified their legendary *Pulotu*, or Western Island of the Blest, with *Buro* in Malaysia, which is accordingly taken as their probable starting-point. But from whatever place they set out, they seem to have settled first in Samoa, which may therefore be taken as their second point of dispersion "From this centre, and more particularly from the Island of Savaii, the principal of the group, their further migrations may be traced with some certainty from archipelago to archipelago through the uniform traditions of the various groups. In these traditions Savaii[1] is constantly

[1] This word *Savaii* has by some been identified with *Java* But the primitive form seems undoubtedly to have been Savaiki in which both *s* and *k* are organic On the other hand Java is the Sanskrit *Javak* for *Djavak*, the two-stalked barley, where the initial organic is *d*, dropped as in the Latin *Janus* for *Dianus* (root *dus*) Besides although there are many Sanskrit words in the Malay dialects there are none in the Sawaiori, the Caucasians having migrated eastwards long before the appearance of the Hindus in the Archipelago Hence although they may have

FIG 14—Caucasian Type, Indo China King of Camboja.

FIG. 15—Caucasian Type, Indo-China Stieng Savage, Cochin China

referred to under diverse forms as the original home of the race, or otherwise persists, as shown in the subjoined list, which will also serve to illustrate the permutation of letters in all these closely-connected dialects :—

SAVAIKI.—Organic Sawaiori form of the word.

SAVAII.—The Samoan form; here still the name of the island referred to in the Sawaiori traditions.

HAVAII—The Tahitian form; here "the universe," "the world" in the national odes, also the old capital of Raiatea Island.

AVAIKI—The Rarotonga form; here "the land under the wind."

HAWAIKI.—The Maori form; here the land whence came the first inhabitants of New Zealand.

FIG 16—Caucasian Type, Indo-China Statue of the Leprous King, Founder of Ongkor-Vâht, Camboja.

HAVAIKI—The Marquesas form; here "the lower regions of the dead" Over the victims in human sacrifices are uttered the words, "To fenua Havaiki" = Return to the land of thy forefathers

HAWAII.—The Sandwich form; here still the chief island of the group.

HEAVAI.—The form in chart published by R. Forster in vol. v. of Cook's Second Voyage, and based on information furnished by Tapaia, a native of Tahiti, who had no personal knowledge of Samoa.

HEAWIJE.—The form given by Cook in his account of his first visit to New Zealand (1770).[1]"

started from Java, they could not have carried its present name with them. I note that Prof Sayce now identifies *Janus* with the Etruscan *Ani*, accounting for the *J* by assimilation with *Janua* (*Academy*, August 21, 1880). But is not *Janua* itself a derived form from *Janus*, whence also *Jannarius*?

[1] "Philology and Ethnology of the Inter-Oceanic Races," by A. H. Keane, in Stanford's "Australasia," 1879.

Dates have even been assigned for these various migrations. Thus we are told that the Polynesians made their appearance in the Marquesas Islands about the beginning of the fifth century A.D., in Tahiti about 1100, in Rarotonga about 1200, in New Zealand about 1400, and so on. But all this, depending on the oral genealogies of the chiefs, and other equally unreliable data, must be regarded as pure conjecture. More probable is the statement that the race appeared in Malaysia over a thousand years before any mention occurs of Malays in that region. At the same time it is idle to attempt assigning dates to strictly prehistoric events, with the correct sequence of which we are more concerned.

The Sawaiori are one of the finest races of mankind, Caucasian in all essentials, and without a trace of Mongolian blood. Observers, from Cook to the members of the *Challenger* Expedition, are unanimous in describing them as distinguished by their fine symmetrical proportions, tall stature, handsome and regular features. Cook gives the palm to the Marquesas Islanders, who, "for fine shape and regular features, surpass all other natives." The Samoans and Tahitians are very little inferior, and even of the Tongans (Friendly Archipelago) Lord George Campbell remarks — "There are no people in the world who strike one at first so much as these Friendly Islanders. Their clear, light copper-brown coloured skins, yellow and curly hair, good-humoured and handsome faces, their *tout ensemble*, formed a novel and splendid picture of the *genus homo*, and as far as physique and appearance goes they gave one certainly an impression of being a superior race to ours." Their average height is five feet ten inches, ranking in this respect next to the Tehuelches of Patagonia; they have smooth but not lank hair, often curly and wavy, and Mr. Staniland Wake has recently shown that, against the commonly-received opinion, the beard is naturally full, though often artificially removed. Add to all this a cheerful joyous temperament, a frank and truthful disposition and kindly nature, and you have a type as different as it is possible to imagine from the Mongolian, and consequently from the true Malay. Yet the Sawaiori and Malays are grouped together under the collective designation of "Malayo-Polynesians," as if they were merely two varieties of a common stock. All they have in common are one or two cranial features, of no particular value as racial tests, at least when taken apart, and the elements of their language, which we shall see is in this instance no racial test at all. The true affinities of the Sawaiori are with the Caucasians of Indo-China, and with that fair element in Malaysia which Dr. Hamy proposes to group as Indonesians, and whose relations to the Eastern Polynesians he has been one of the first to perceive. Noteworthy amongst these Indonesians, Pre-Malays, or Indo-Chinese Caucasians still unaffected by Mongol influences in the Archipelago are the Mentawey Islanders, who, though occupying the Pora Group some seventy miles off the west coast of Sumatra, are none the less closely related in physique, language, and customs, to the Eastern

FIGS. 17, 18.—Mongoloid Types, Indo-China. King and Queen of Siam.

Polynesians. On this point the testimony of C. B. H. von Rosenberg is decisive. "On a closer inspection of the inhabitants the careful observer at once perceives that the Mentawey natives have but little in common with the peoples and tribes of the neighbouring islands, and thus as regards physical appearance, speech, customs, and usages, they stand almost quite apart. They bear such a decided stamp of a Polynesian tribe that one feels far more inclined to compare them with the inhabitants of the South Sea Islands."

From this point of view it will be instructive to compare the native of Pora, Mentawey Group (Fig 19), with the Battas of Pak-Pak, Sumatra (Figs. 20 and 21), all from von Rosenberg's "Malay Archipelago," vol. i. pp 56 and 192. Owing to their splendid physique and "Caucasian features" Junghuhn and Van Leent take

FIG 19 —Caucasian Type, Malaysia. Mentawey Islander

these Sumatran Battas as the typical unmixed or pre-Malay element in the Archipelago, whom they would accordingly group collectively as the Batta race The form *Battak* often occurs, but this is simply the plural of Batta, so that to write *Battaks*, as many do, is a solecism. Compared with the Malays proper, the Battas are tall and muscular,

FIG 20 —Caucasian Type, Sumatra Native of Batta Land

with regular features, less prominent cheek-bones, light-brown complexion, with a ruddy tinge on the cheeks, finer hair, often brown and wavy, thicker beard. When in Jilolo in 1876 M. Achille Raffray met some so-called "Alfuros" of Dodinga, who might be taken as typical specimens of this Batta or Indonesian race (*Tour du Monde*, April 12, 1879, p. 234) We therefore separate this Batta, Indonesian or Pre-Malay element in the Archipelago from the Malay element proper, affiliating the former to the Indo-Chinese and Eastern Pacific Caucasians, the latter to the Indo-Chinese Mongolians Whether the Caucasians are found in other parts of East

FIG 21 —Caucasian Type, Malaysia Native of Pak-Pak, Batta Land

Asia is a question that cannot here be discussed, but it may be remarked that even the cautious Topinard ventures to include "the Ainos of Japan, the Miau-Tz' and the Lolos of Yunnan in the European group" ("Anthropology," p 476)

C MONGOLIAN TYPE

VI. CONTINENTAL BRANCH. *Indo-Chinese Group*

VII OCEANIC BRANCH *Malayan Groups*

The main features of the continental branch of this division are too well known to need special comment here. What we are more immediately concerned with is its relation to the Oceanic section, and this relation will come out the more clearly if both are treated together. To avoid misconception, it may be well to observe that a portion only of the Continental branch is comprised in the Indo-Chinese group, for there are many other groups, such as the Mongolian proper, the Manchurian, the Tatar or Tûrkic, the Japanese, the Corean, the Finnic scattered over the greater part of Asia and penetrating westwards to the Baltic seaboard and Middle Danube basin. All these must be held, apart from the question of miscigenation, to belong to one primeval stock, constituting the Yellow or Mongolian division of the human family. We are all familiar with its essential characteristics flat and broad features, prominent cheek-bones, short broad and flat nose, black almond-shaped and oblique eyes, long black and lank hair nearly cylindrical in section, little or no beard, low stature averaging about 5 feet 4 inches, dirty yellow or tawny complexion, slightly prognathous and more or less brachycephalous head.

This description corresponds substantially with the ordinary Malay type, such as we see it in Java, Bali, Madura, many parts of Sumatra, round the coast of Borneo, and in the peninsula of Malacca The true aborigines of this region, as shown in a previous section, were the Negritos; consequently the Malays, like the

pre-Malays or Caucasian Indonesians, are here intruders Intruders from where? Obviously from where the type exists, the neighbouring Indo-Chinese peninsula What then becomes of the Malay as a primary division of mankind? As such it can no longer be recognised in anthropology, and must sink to the position of a mere variety of the Mongol type. The so-called true Malay or typical Malay is essentially a Mongolian, and the likeness between the two has not failed to strike all careful observers "The Malayan race," says Wallace, "as a whole undoubtedly very closely resembles the East Asian populations from Siam to Manchuria. I was much struck with this, when in the Island of Bali I saw Chinese traders, who had adopted the costume of that country, and who could then hardly be distinguished from Malays, and on the other hand I have seen natives of Java who, as far as physiognomy was concerned, would pass very well for Chinese" Hence De Quatrefages rightly rejects the claim of the Malays to be regarded as a fundamental type "All polygenists," he remarks, "have regarded the Malays as one of their *human species*, many monogenists have considered them as one of the principal races I showed long ago that in reality they are only a mixed race in which white, black, and yellow elements are associated"

The last clause of this sentence gives the true solution of the problem The inhabitants of Malaysia consist not of one, nor even of three distinct races, but of three races variously intermingled, the yellow or Mongolian, and the white or Caucasian chiefly in the west, these two and the black or Papûan chiefly in the east. As the fusion of yellow, white, and black produces the so-called "Alfuros" in the east, so the fusion of yellow and white produces the so-called Malays in the west The more the yellow prevails the nearer do the Malays approach the Mongol type, the more the white prevails the nearer do they approach the Caucasian type, until in some places they seem to be no longer distinguishable from the Mongols, in others from the Caucasians The Javanese are taken for Chinese by Wallace, just as the Mentawey Islanders are taken for Sawaiori or Eastern Polynesians by von Rosenberg Under these circumstances it is not surprising that those who seek for unity in the Archipelago should meet with nothing but confusion Prof Flower comments on the divergent characteristics presented by the Malayan crania, remarking that "there is certainly no very great conformity in the characters of the skulls in our collections which are said to belong to Malays" This must always be the case until we come to an understanding as to the meaning of the term Malay, which after all is far more a national and linguistic than a racial expression Proceeding on the groundless assumption of a common Malay type in Oceanica, Welcker arrived at the subjoined astonishing results from cranial measurements in Micronesia and Malaysia alone.—

Length of Skull 100

	Index of breadth	Index of height	Difference
Caroline Islanders	68	74	+ 6
"Alfuros"	74	79	+ 5
Dyaks of Borneo	75	77	+ 2
Balinese	76	77	+ 1
Amboynese	77	77	+ 0·4
Sumatran	77	78	+ 1
Macassar	78	78	− 0·5
Javanese	79	80	+ 0·4
Buginese	79	80	+ 0·4
Menadorese	80	81	+ 1
Madurese	82	82	− 0·1

Yet even here Sumatran is taken as a unit, although it is not hazarding too much to say that a comparison of Atyeh, Batta, Palambang, Jambi, Siak, Menangkabu, Korinchi, Rejang, Lampung, and other crania from that island alone would probably yield almost as many discrepancies as are revealed in this table. There is in fact less uniformity of type in Malaysia alone, with a population of some 25,000,000, than in the whole of China and Mongolia with a probable population of 400,000,000

A H KEANE

(*To be continued*)

A CHAPTER IN THE HISTORY OF THE CONIFERÆ

II.

GINKGO (Linnæus)

THE perhaps better known name of this genus is Salisburia (Smith), but the Linnæan name, adapted from the Chinese, has unfortunately priority. The genus contains only one existing species, the gigantic *Ginkgo biloba* of Northern China and Japan It is classified with the Taxeæ, is diœcious, and the flabelliform leaves are deciduous, leathery, very variably lobed, and of all sizes up to an extreme of five inches across The fruit, about an inch in diameter, is drupaceous, on a slender footstalk, composed externally of a fleshy layer, and internally of a hard light-coloured shell, and is somewhat unsymmetrical, owing to the abortion of one of the seeds. The foliage is like that of the maidenhair fern, but the petiole is stout, often three inches long, and distinctly articulated at the base An important characteristic in recognising the fossil leaf, besides the petiole, is that however irregularly they may be lobed, they are almost invariably primarily bilobed

Though so restricted a genus now, its ancestry is perhaps more venerable than that of any other forest tree The Carboniferous fruits Trigonocarpus and Noeggerathia are believed by both Hooker and Saporta to have belonged to some ancestral form, and even the foliage of the latter, Psygmophyllum of Schimper, approaches nearly to that of Ginkgo Baiera, beyond doubt a close ally, appears in the Permian, and Ginkgo in all probability in the bilobate Jeanpaulia of the Rhœtic of Bayreuth, but the group did not reach its maximum until the Jurassics. A few species have been described in other works, but Heer's Jurassic flora of Eastern Siberia ("Flora foss. Arctica," vol. iv) contains by far the most important contribution to their past history. Five genera are placed in the groups *Phœnicopsis*, *Ginkgo*, *Baiera*, *Trichopitys*, and *Czekanowskia*, but there is no special character uniting the latter to Ginkgo, although it is no doubt coniferous. The remains are clusters of occasionally forked acicular leaves, sheathing at the base in imbricated scales. The leaves widen in most specimens here and there into bead like expansions, inferred to have been caused by some extinct type of parasitic fungus It is thought by Heer that a detached stem bearing shortly petiolated double seeds or nuts may be their fruit. Phœnicopsis is a cluster of separate leaves, also sheathing in scales at the base, but forming a fine palm like foliage, thought by Heer to unite Cordaites and Baiera, yet without any direct affinity with Ginkgo

The most aberrant of the genera obviously belonging to the group is Trichopitys of Saporta. In this the leaves were smaller, with fewer veins, and the parenchyma reduced to a narrow expansion margining each vein Although so extreme a modification of the normal type, *T setacea*[1] possesses the characteristic bilobation and petiole. Its affinity is best traced through *G. concinna*, which is similar, but with the segments of the leaves expanded to receive two to three veins each

G. sibirica and *G. lepida* are separated on trivial grounds not supported by the illustrations, and when united furnish the chief and most abundant leaves in the deposit. These are nearly as large as in the existing species, but more digitate, and with about five veins to

[1] *T pusilla* probably belongs to some other division of the vegetable kingdom

each segment They have the venation, bilobation, and petiole of Ginkgo, yet approaching in their larger leaves to Baiera Other similar species (?) diminishing in size are *G. schmidtiana*, with about six segments, *G flabellata*, with fourteen or fifteen segments, and *G pusilla*, with a less number, and barely an inch across the base These three might probably be united into a single species The remaining form from Siberia, *G huttoni*, is less divided, having but four rounded segments, and is in that respect a nearer approach to the existing one.

The nearest, however, is *G digitata* from the Jurassic of Spitzbergen, which, but for smaller size and thicker petiole, might be placed in the existing species. Leaves from Scarborough, said to be of the same species, are larger *G integriuscula* is evidently the smaller and less lobate leaf of the same species, and the author has besides taken the unnecessary care to establish five duly named and lettered varieties, thus clearly showing that he had formed no adequate conception of the extent to which the leaves of the existing tree may vary, even on the same branch His species should be reduced, the excessive subdivision being a disadvantage and rendering the work unwieldy The author also changes the classification of the Coniferæ between the second and third volumes, and the name for this genus between the third and fourth volumes, without explanation or notice, which, in a work addressed especially to geologists, is an inconvenience

The third genus, Baiera, possesses a larger and more palm like leaf, averaging nearly five inches in radius, primarily bilobed, each lobe forking either once or twice, the ultimate segments being of uniform width and possessing four parallel veins each The leaf tapers to the petiole, which is not preserved in the engraved specimens The bilobation and venation connect it sufficiently with Ginkgo, and the persistence of these characters throughout the whole group, which would hardly have been suspected to have a morphologic value, is peculiarly remarkable

There is a marked diminution in the group in the Cretaceous Baiera from the Komeschichten is limited to vestiges of stunted form placed among the ferns, while Ginkgo appears in a starved species with small leaves and short thick petiole, described as *Adiantum formosum*, and by fragments from the Upper Cretaceous Ataneschichten, inappropriately named *G primordialis*

In the Arctic Eocenes (Miocene of Heer) Ginkgo has only, and that very sparingly, been met with in Greenland This variety so resembled *G adiantoides* of the Italian Miocenes, that Heer almost directly abandoned his specific name *primordialis*, and became doubtful even whether both should not be united with the existing species.

The small fragments figured in the Miocene Baltic flora are inconclusive, and we only again meet with it in the Miocenes as far south as Italy, the South of France, and the Mississippi[1] It has been said to occur in English Eocenes by Heer, who wrote upon the tracing of an Adiantum from Bournemouth, "this is a Ginkgo," and by Ettingshausen, who considers four seeds from Sheppey to belong to it, although less than half the size of those of the present Ginkgo, and rather materially differing Its absence otherwise in British and in French Eocenes, and in the Swiss and Austrian Tertiaries, is ascertained, for the occurrence of so distinctly-marked and easily-preserved a leaf could not well be overlooked

The very strongly-marked and exceptional characters of Ginkgo, shared by the allied extinct genera, the remoteness of its origin in the Carboniferous, its extensive development in the Mesozoic, and persistence through so many ages, seems to render it desirable to separate them from the Taxeæ into a distinct tribe Already dying out in the Cretaceous and lingering through the Tertiaries in a single species, its existence now is a mere survival

[1] Since writing the above, Saporta informs me that the supposed Mississippi species is really a Lygodium

Its home has been from time to time within the Arctic circle, yet it is scarcely proved, as Saporta says, that it actually originated there The leaf of *G digitata* from the Scarborough oolite, figured by Schimper, is far larger than any figured from Spitzbergen, and neither the foliage nor the fruit of the northern fossil Ginkgo, it appears, ever at any time approached those of the existing tree in its native habitats. It is now indigenous to the northern provinces of China, and must therefore be capable of withstanding a rigorous climate, yet the conditions in Western Europe do not appear to favour the ripening of its seed in higher latitudes than the South of France

Its distribution during the Tertiaries is instructive, and Saporta's explanation, that it existed in the north during the warm Eocene and pre-Eocene times, and descended thence across Europe as the temperature decreased, on the approach of the Miocene time, is the only one that explains the facts. To suppose with Heer that the same species lived contemporaneously and at the same level in Italy and in Disco is absurd, and would presuppose a uniformity of climate such as no natural causes could have produced at so recent a geological period J STARKIE GARDNER

NOTES

THE Roman Academy of Sciences has awarded half of the King Humbert Prize, now awarded for the first time, to the German astronomer, Dr Wilhelm Tempel, director of the Acetri Observatory at Florence, for his observations on nebulæ.

DEATH is levying heavy contributions from the students of entomology in France, more especially as regards the oldest and best known We very recently had occasion to notice the decease of Etienne Mulsant, at a ripe age. Now, we regret to have to announce the death of Achille Guenée of Châteaudun, whose name is probably more known in England than is that of any other French entomologist He died on the 30th ult (his colleague and fellow-worker, Dr Boisduval, died on December 30, 1879), in his seventy-second year Guenée was a lepidopterist His publications are very numerous The most important of all are the six volumes of the series termed the "Suites à Buffon" on some of the principal families of the *Lepidoptera* of the world, which appeared from 1852 to 1857 These volumes formed a basis for future students of *Lepidoptera*, and largely influenced those of them amongst our own countrymen The town of Châteaudun occupies a not unimportant position in the history of the Franco-Prussian war. Guenée's house was occupied by the Prussian troops. He himself took refuge in Geneva, and, true to his predilections, studied the *Lepidoptera* in the collection of the museum of that city, the results of his investigations were published. We believe that when circumstances permitted his return, his own collections were found to have suffered very little damage at the hands of his unbidden guests He was an officer of the French Academy Our Entomological Society of London elected him one of its honorary members many years ago, and his friends amongst Englishmen were not few

JOHN DUNCAN, a poor Aberdeenshire weaver, has presented to the University of Aberdeen his herbarium of nearly 1200 British plants, gathered by him all over the country from Northumberland to Banff, while acting as a harvest labourer The story of Duncan was told in *Good Words* for 1878, by Mr. William Jolly, and now it would seem that the poor and intelligent weaver is so reduced in circumstances as to be compelled to accept parochial relief Surely the University of Aberdeen ought to do something for him, and possibly some of our readers may care to send a trifle to John Duncan, Droughsburn, by Alford, Aberdeenshire.

LEIPZIG is at last to have a zoological garden. A number of citizens intend to form a company for the purpose of establishing a zoological garden on an area of twenty acres, with conservatories, &c. The civic authorities of Leipzig have given their consent, and pointed out a suitable place in the immediate environs of the city.

THE base of the Mont Cenis tunnel at the French entrance shows such ominous signs of sinking that the Paris-Lyons Mediterranean Railway Company intend to have another entrance to the tunnel bored, which is to be situated at about 1 kilometre's distance from the present entrance, and is to reach the old tunnel at a spot about 600 metres from its mouth. The work has already been commenced.

VISITORS to the Brighton Aquarium will regret to hear of the death of the fine male sea-lion (*Otaria stelleri?*), so long an inmate of the Institution. Mr. A. Crane sends us some details about the animal. Poor "Jack's" very sudden death is attributed to disease of the heart. The left lobe of that organ was found ruptured and in a state of complete collapse. His female companion is still in good health. The first offspring of the pair, a male cub, was born in the spring of 1877; the second, a dead female, in the following year. Jack was probably about twelve years of age at his death. His length was 8 feet 5 inches, maximum girth 5 feet 3 inches; fore-feet 4 feet 2 inches, and hind flippers 17 inches; greatest circumference of the head 2 feet 10 inches, frontal 2 feet 2 inches, round the jaws, under the eyes, 17 inches; weight of skin 1 cwt., of lungs 22 lbs. As the skeleton will be preserved in the Institution zoologists will be able to finally determine by means of the skull the exact species to which this male belonged. The cub born of this pair is now four years old, a fine animal 6 feet long and much larger than his somewhat diminutive and flat headed mother, to whom at present he bears most resemblance, the extraordinary prominence of the frontal bones of the skull characterising his male parent being as yet undeveloped. The tanks, Mr. Crane states, are in excellent condition, and the growth of sponges, tunicates, and development of invertebrate life generally is very remarkable. In fact to a qualified histologist and embryological student they would furnish ample material for a vacation, and doubtless yield interesting results. Facilities for study, we are informed, would be willingly accorded by the Management.

PROF. E. MORREN'S *Correspondance botanique* grows in size and in completeness. We have now before us the eighth issue (October, 1880) of this most useful botanical directory. In Europe and the United States the list of botanists, official and others, is now very full and complete; and scarcely any quarter of the globe can be named which is not represented by one or two names. Every working botanist should have it on his library table.

AT a quarter to 5 p.m. on January 5 a somewhat violent shock of earthquake was felt at Agram. It lasted about three seconds. The ground rose in wave-like curves as the shock passed over. On the previous night two slight shocks were experienced.

THE *Times* Bucharest correspondent, under date January 4, describes a curious result following the recent earthquake which passed under that city. The soil of Bucharest is a rich, black, porous vegetable mould, very springy under pressure, and carriages passing in a street cause a strong vibration in the adjacent houses. The Grand Hôtel Boulevard, however, was an exception to this general rule, and in the correspondent's room, facing the principal street, on which there is a heavy traffic, he never could feel any sensible effect from passing vehicles. During the recent earthquake the windows and crockery in less massively constructed buildings rattled very sensibly, whereas there was no audible sound produced in the hotel mentioned. Since the earthquake shock, however, this state of things has changed entirely, and every vehicle passing the hotel causes vibration in the whole building. The singular part of this change consists in the fact that the effect produced by the vehicle is precisely the same as that accompanying the earthquake. It is not a jar as previously produced in other buildings, but a sawing motion similar to that described in the correspondent's telegram relating to the late shock of earthquake. This movement is so great as to cause pictures to sway backwards and forwards on the walls, and it is equally perceptible in the rear corner rooms farthest from the street. The hotel is of brick, covered outside with mastic, which would show at once any crack in the walls. He has carefully examined the exterior of the building and there is not a crack in it. Hence, he thinks, this change in the solidity of the structure appears to be due to some effect produced in the earth underneath the building by the shock of earthquake.

THE *Daily News* Rangoon correspondent, writing on December 10, states that they had another shock of an earthquake in Burmah three days before the same day on which Agram was revisited. In Rangoon it was not severe, but the tremulous motion lasted for fully a minute and a half, and was sufficiently strong to set pictures swinging and rattling against the walls. Like those which preceded it, the shock travelled from south to north, and was felt more violently elsewhere, though in no case so intensely as to cause serious damage.

ON the 6th inst., at 4.30 a.m. Berlin time, a pretty strong shock of earthquake was felt at Rousdorf.

DR. KRISHABER of 41, rue de la Bienfaisance, Paris, writes to ask if any of our readers can give him information as to the causes of death in monkeys in a wild state.

THE appearance of the phylloxera in the Crimea has been the subject of a communication, by M. Porchinsky, to the St. Petersburg Entomological Society. It has appeared probably in consequence of vines having been imported from France, and has extended hitherto very slowly in small concentric circles. As the vineyards are situated on the southern coast of the Crimea in the shape of a narrow strip at the foot of the mountains, M. Porchinsky thinks that the devastating insect will not cause much destruction. But if it appeared on the Caucasus, especially among the numberless wild vineyards of that country, it might completely destroy the whole of the vines in the valleys of the Rion and Kura rivers.

MR. F. W. PUTNAM has made a communication to the Essex (U.S.) Institute of peculiar interest on "The Former Indians of Southern California, as bearing on the origin of the Red Man in America." He called attention to the facts relating to the antiquity of man on the Pacific coast, and to the importance of the discovery in California of human remains and of the works of man in the gravel, under beds of volcanic material, where they were associated with the remains of extinct animals, and to the necessity of looking to this early race for much that it seems otherwise impossible to account. He thought that what is called the "Eskimo element," in the physical characters and arts of the southern Californians, was very likely due to the impress from a primitive American stock, which is probably to be found now in its purest continuation in the Innuit. In this connection he dwelt upon the probability of more than one type of man. In following out this argument he called attention to the distinctive characters in different tribes of Indians on the Pacific coast, and stated his belief that they had resulted from an admixture of the descendants of different stocks. The Californians of 300 years ago, he thought, were the result of development by contact of tribe with tribe through an immense period of time, and that the primitive race of America, which

was as likely autochthonous as of Asiatic origin, had stamped its impress on the people of California The early men of America he believed were dolichocephali, and the short-headed people he thought were made up of a succession of intrusive tribes in a higher stage of development, which in time overran the greater part of both North and South America, conquering and absorbing the long-headed people, or driving them to the least desirable parts of the continent. He thought that the evidence was conclusive that California had been the meeting ground of several distinct branches of the widely-spread Mongoloid stock, for in no other way could he account for the remarkable commingling of customs, arts and languages, and the formation of the large number of tribes that existed in both Upper and Lower California when first known to the Spaniards Mr Putnam then gave a review of the arts of the Californians and the physical characters and customs of the people, showing that, notwithstanding the absence of pottery, the tribes, when first known, had passed through the several stages of savagery and had reached the lower status of barbarism of the "ethnical periods" given by Morgan.

PROF. SCHÄFER's course of eleven lectures on the Blood at the Royal Institution will begin on the 25th instant instead of the 18th. Mr. Francis Hueffer's course of four lectures on the Troubadours will begin on the 27th instant instead of the 20th, and Prof Sidney Colvin's course of four lectures on the Amazons will begin on the 29th instant instead of the 22nd

PART 2 of vol vii of the "Natural History Transactions of Northumberland, Durham, and Newcastle-on-Tyne" has just been issued (Williams and Norgate). The part contains an interesting memoir of the late Mr W C Hewitson, F L S., by Dr. Embleton, accompanied by a good photograph There is a long paper by Mr. Hugh Miller on Tynedale Escarpments, their pre-glacial, glacial, and post-glacial features.

HERR E REYER has published a little pamphlet containing some interesting notes on the history of tin

AT the meeting of the Eastbourne Natural History Society of December 17, 1886, Mr Charles Foran read "Notes on some of the Beetles of the Cuckmere District"

THE Municipal Council of Paris has given authority to the Lontin Company to light the Place du Carrousel with electricity. A contract has been signed by the Lyons and Mediterranean Company for illuminating, by the Lontin light, all the principal railway stations on their system Experiments have been tried at Marseilles and have been carried out successfully.

FROM January 1 *L'Electricité* and *La Lumière Electrique*, two French electrical papers, will appear every week instead of every fortnight.

THE German Society of Eastern Asia, having its headquarters at Yokohama, has sent us the last four parts of its *Mittheilungen*. This Society is evidently doing a very useful work in collecting information on a great variety of subjects connected especially with Japan. The parts sent us contain papers on such subjects as Japanese proverbs, diseases, songs, population statistics, mining, cremation, the "Go" game, coins, and the chalk formation of Yedo. Asher and Co. of Berlin are the European agents of the Society

WE find in the *Journal de Genève* the following figures as to the very warm winter which is experienced during this year on the shores of Lake Leman, as compared with the unusually cold winter of the year passed. In December, 1879, the maximum daily temperature at Geneva was only five times above zero, and the average was +6°·4 Cels., whilst the average of the maximum temperatures of the remaining twenty-six days was -4° 5 Cels. As to the minima they were only twice above zero, and their average was +2°·9, whilst the average of the remaining twenty-nine minima was -9° 7 In December, 1880, the thermometer was only six times below the melting-point, and the average of the cold minima was -0°·7, whilst the average of the minima for the other twenty-five days was +3° 8 As to the maxima they fell below zero, and their average is as high as +9°·1 The greatest cold experienced during December, 1879, was -15° Cels., and only -1° 5 in 1880, the warmest temperature observed during December, 1879, was +8° 9, and +13° Cels in 1880.

A TEA plantation was established last year by Count d'Amigo upon his estates, situated near Messina The tea plant is said to thrive perfectly well there, and its leaves are said to be in nowise inferior to those of the Chinese plant In order to dry them in a rational manner and to prepare them for export as well as for home consumption, a Chinese expert is to become the manager of the Messina plantations.

THE Wissenschaftliche Centralverein at Berlin held its annual general meeting on December 13, 1880 The secretary, Dr Max Hirsch, in his yearly report stated that the principal efforts of the Society had been directed towards furthering the progress of the Humboldt Academy, which was founded by the Society some two years ago, and which since that time shows a total of ninety-two courses of lectures, which were delivered before 3366 students and a still larger number of "hospitanten," *i e* casual students. Apart from these lecture-courses the Society has for this winter arranged for a number of single lectures by eminent men of science The establishment of a large reading-room is also planned.

A YOUNG Men's Society for Home Study has been started in the United States The aim of the Society is to guide and encourage young men desirous of systematic study and reading at home by opening to them, by means of correspondence, systematic courses in various subjects Courses of reading and plans of work are arranged, from which men may select one or more, according to their taste and leisure, and aid is given them, from time to time, through directions and advice The courses offered by the Society at present (more may be added as the demand for them becomes known) are: Course 1. American and English History Course 2 English Literature Course 3 German Literature. Course 4 Natural Science: Sec. 1, Botany, Sec 2, Zoology, Sec. 3, Geology. Course 5. Mathematics. Mr. Samuel H. Scudder is head of the Natural Science Department.

THE simplest post-office in the world is in Magellan Straits, and has been established there for some years past It consists of a small cask, which is chained to the rock of the extreme cape in the straits, opposite Tierra del Fuego Each passing ship sends a boat to open the cask and to take letters out and place others into it The post-office is self-acting therefore; it is under the protection of the navies of all nations, and up to the present there is not one case to report in which any abuse of the privileges it affords has taken place

OUR ASTRONOMICAL COLUMN

WINNECKE'S COMET.—Reference has been already made in this column to the very unfavourable circumstances attending the actual return to perihelion of the short-period comet of Winnecke, and so far there is no intimation of its having been detected even with telescopes of the greatest optical capacity. Indeed, as will be seen from Prof. Oppolzer's communication in the *Astron Nach* No 2326, though he gave an accurately-computed ephemeris extending to January 24, he considered the chance of perceiving the comet a very remote one The perihelion passage took place on December 4, and the intensity of light is now very small, not greater than half that at the date of the last observation in 1858. The comet sets less than 1h. 45m.

after the sun. The later positions in Prof. Oppolzer's ephemeris are as follows —

12h. Berlin M.T

	R.A. h m s	N P D ° ′	Log distance from Earth
January 16	21 29 12	109 41·4	0 2836
18	21 38 18	109 9 7	0 2875
20	21 47 12	108 36 9	0 2916
22	21 55 54	108 3 2	0 2959
24	22 4 23	107 28·6	0 3002

SWIFT'S COMET.—Mr. Common, with his reflector of three feet aperture at Ealing, has observed this comet for position as late as January 5, when it was not yet considered the *extremum visible* in the instrument. Accurate observations were made by Mr. Lewis Boss at the Dudley Observatory, Albany, U.S., on October 11, the night after discovery, so that there will be a good extent of observation upon which to determine the orbit at this appearance.

MINIMA OF ALGOL—The following epochs of geocentric minima of Algol are deduced from Prof. Schonfeld's elements That very sensible perturbations have taken place during the last few years is shown by a comparison of these elements with the observations of Prof Julius Schmidt of Athens; thus the mean errors since 1875 are, for 1875·76 − 4 8m., 1876 76 + 19·4m, 1877 73 + 40 8m.; 1878 78 + 21 3m The star is well deserving of attention during the present year

	G M T. h m		G M T h m
January 21	18 20	February 13	16 54
24	15 9	16	13 43
27	11 58	19	10 32
30	8 48	22	7 22
February 2	5 37		

CERASKI'S VARIABLE IN CEPHEUS—A series of minima of this star visible in Europe commences about January 13, continuing until May. The period may be taken = 2·492913d or 2d 11h 49 795m, and if we reckon from the second minimum completely observed by Prof Schmidt on October 18, 1880, we shall find a minimum on January 18 at 17h. 41m. G M. T, and successive visible epochs may be inferred by adding 4d 23h 39 59m.

ELONGATIONS OF MIMAS—According to the elements previously adopted in this column for indicating approximately the times of greatest elongations of this very difficult object, the satellite would be at the western extremity of its apparent orbit at the following Greenwich times —

	h m		h m.
January 19	11 5	January 22	6 56
20	9 42	23	5 33
21	8 19		

The elements upon which Prof. Newcomb's manuscript tables adopted in the *American Ephemeris* for 1882 and 1883 are founded appear to give the times of the elongations later by some forty minutes.

THE ACADEMY OF SCIENCES, PARIS—The recent election of Dr. Warren De La Rue as Correspondent of the Academy of Sciences of the Institute of France, Section of Astronomy, in place of the late Sir Thomas Maclear, nearly completes the usual number of correspondents in this section, upon which several vacancies had existed for some time The roll is now as follows, taking the names in alphabetical order—Adams (Cambridge), Cayley (Cambridge), De La Rue (London), Gyldén (Stockholm), Hall (Washington), Hind (London), Huggins (London), Lockyer (London), Newcomb (Washington), Oppolzer (Vienna), Plantamour (Geneva), Roche (Montpellier), Schiaparelli (Milan), Stephan (Marseilles), and Struve (Pulkova). The Astronomer-Royal is one of the eight Foreign Associates of the Academy

GEOGRAPHICAL NOTES

WE are glad to learn that the rumour of the murder of Herr Hildebrandt in Madagascar is unfounded.

THE first number of the memoirs (*Zapiski*) of the West Siberian Branch of the Russian Geographical Society contains valuable papers by M. Kostroff on witches in the Government Tomsk, by M. Grigorovsky, on the peasantry in the Narym district; by M Pyevtzoff, on his journey through Djoungaria, with a map, and by M. Balkashin, on trade *viâ* the Ob River with Europe during the years 1877 and 1878

AT one of its recent meetings the Russian Geographical Society discussed the proposal of Mr Fleming, transmitted to the Society by the Governor-General of Canada, as to the adoption of a universal time and of a universal first meridian. As to the suggestion to have a cosmopolitan noon at the same moment over the surface of our globe, the Society thinks that it would meet with a mass of difficulties as to its application in daily life, but the advantages which a universal time would afford being very great, the Society expresses the wish that the whole question be earnestly discussed and studied by learned societies. As to the first meridian, the Society, which already discussed the question in 1870, maintains its former resolution, namely, that the meridian of Greenwich, or at least that of Behring Strait, 180° distant from that of Greenwich, should be accepted by the whole civilised world as a first meridian.

WE have received the annual reports for 1879 of the Siberian, Orenburg, and Caucasian branches of the Russian Geographical Society, which has had the happy idea to publish all the reports together in one volume, thus rendering accessible for the general reader who knows Russian this most valuable geographical information, formerly disseminated in local publications The oldest of these branches, the East Siberian, has endured heavy losses during the great fire at Irkoutsk. Its rich zoological, botanical, geological, and ethnographical collections were all destroyed by fire. the beautiful head of a *Rhinoceros tichorhinus*, just received from Verkhoyansk, the rare collection of samples of gold from all the gold-mines of Eastern Siberia, palæontological collections not yet described, and so on, as well as the 10,230 volumes of its rich library, and collections of old records, were all destroyed by fire Several scientific bodies, Russian and foreign, have already sent their publications and duplicates from their libraries, so that the museum and library already are in way of reconstitution

THE third volume of the "Rajputana Gazetteer" has just been issued from the Government press at Simla. The various sections into which it is divided are contributed by Capt C E. Yate, Major C A Baylay, and Major P W. Powlett, and treat of general topography, history, population, trade, towns, &c Mr J F. Baness, the chief draughtsman in the geographical and drawing branch of the Survey of India, has in the press at Calcutta a work entitled "Index Geographicus Indicus" It will be published in one volume, with eight coloured maps, and will comprise a list, alphabetically arranged, of the principal places in our Indian Empire, accompanied by much statistical, political, and descriptive information.

A SERIES of papers is commenced in last week's issue of *Les Missions Catholiques*, on the manners, customs, and religion of the races of the Caucasus

The new number of the *Bulletin* of the Commercial Geographical Society of Bordeaux contains a useful paper on Japan, by M E Labrone

THE Palestine Exploration Society have decided to undertake the exploration of Palestine east of the Jordan.

OBSERVATIONS ON ANTS, BEES, AND WASPS[1]

Power of Communication by something approaching to Language.

IN my previous papers many experiments have been recorded, in which I have endeavoured to throw some light on the power of communication possessed by ants. It is unquestionable that if an ant or a bee discovers a store of food her comrades soon flock to the treasures, although, as I have shown, this is by no means always the case But it may be argued that this fact taken alone does not prove any power of communication at all. An ant observing a friend bringing food home might infer, without being told, that by accompanying the friend on the return journey she might also participate in the good things. I have endeavoured to meet this argument in my third paper (*Linn Journ.* vol. xii. p. 466) by showing that there was a marked

[1] By Sir John Lubbock Bart, M P, F R S, F L S, D C L, LL D, Vice-Chancellor of the University of London Read at the Linnean Society, June 17 Abstract

difference in the result, if on experimenting with two ants one had access to a large treasure, the other only to a small one

It also occurred to me that some light would be thrown on the question by compelling the ant who found the treasure to return empty handed. If she took nothing home and yet others returned with her, this must be by some communication having passed. It would be a case in which precept was better than example.

I selected therefore a specimen of *Atta testaceo pilosa*, belonging to a nest which I had brought back with me from Algeria. She was out hunting about six feet from home, and I placed before her a large dead bluebottle fly, which she at once began to drag to the nest. I then pinned the fly to a piece of cork, in a small box, so that no ant could see the fly until she had climbed up the side of the box The ant struggled, of course in vain, to move the fly. She pulled first in one direction and then in another, but, finding her efforts fruitless, she at length started off back to the nest empty handed. At this time there were no ants coming out of the nest. Probably there were some few others out hunting, but for at least a quarter of an hour no ant had left the nest. My ant entered the nest but did not remain there, in less than a minute she emerged accompanied by seven friends I never saw so many come out of that nest together before In her excitement the first ant soon distanced her companions, who took the matter with much *sang froid*, and had all the appearance of having come out reluctantly, or as if they had been asleep and were only half awake The first ant ran on ahead, going straight to the fly. The others followed slowly and with many meanderings, so slowly, indeed, that for twenty minutes the first ant was alone at the fly, trying in every way to move it. Finding this still impossible, she again returned to the nest, not chancing to meet any of her friends by the way. Again she emerged in less than a minute with eight friends, and hurried on to the fly. They were even less energetic than the first party, and when they found they had lost sight of their guide they one and all returned to the nest. In the meantime several of the first detachment had found the fly, and one of them succeeded in detaching a leg, with which she returned in triumph to the nest, coming out again directly with four or five companions. These latter, with one exception, soon gave up the chase and returned to the nest I do not think so much of this last case, because as the ant carried in a substantial piece of booty in the shape of the fly's leg, it is not surprising that her friends should some of them accompany her on her return; but surely the other two cases indicate a distinct power of communication.

Lest however it should be supposed that the result was accidental, I determined to try it again Accordingly on the following day I put another large dead fly before an ant belonging to the same nest, pinning it to a piece of cork as before After trying in vain for ten minutes to move the fly, my ant started off home. At that time I could only see two other ants of that species outside the nest Yet in a few seconds, considerably less than a minute, she emerged with no less than twelve friends As in the previous case, she ran on ahead, and they followed very slowly and by no means directly, taking in fact nearly half an hour to reach the fly. The first ant, after vainly labouring for about a quarter of an hour to move the fly, started off again to the nest. Meeting one of her friends on the way she talked with her a little, then continued towards the nest, but after going about a foot, changed her mind, and returned with her friend to the fly After some minutes, during which two or three other ants came up, one of them detached a leg, which she carried off to the nest, coming out again almost immediately with six friends, one of whom, curiously enough, seemed to lead the way, tracing it, I presume, by scent. I then removed the pin, and they carried off the fly in triumph

These and other experiments certainly seem to indicate the possession by ants of something approaching to language. It is impossible to doubt that the friends were brought out by the first ant, and as she returned empty-handed to the nest, the others cannot have been induced to follow her merely by observing her proceedings. I conclude, therefore, that they possess the power of requesting their friends to come and help them.

Recognition of Relations.—In my last paper (*Linn. Journ.* vol. xiv. p 611) I recorded some experiments made with pupæ, in order if possible to determine how ants recognised their nest companions. The general result was that pupæ tended by strangers of the same species, and then after they had arrived at maturity put into the nest from which these strangers had been taken, were invariably treated as interlopers and attacked. On the other hand, if they were tended by ants from their own nest, and then after arriving at maturity put back in their own nest, they were invariably recognised as friends, and lastly, if as pupæ they were tended by strangers, but then after arriving at maturity put back in their own nest, they were generally received as friends. In all these experiments, however, the ants were taken from the nest as pupæ, and though I did not think the fact that they had passed their larval existence in the nest could affect the problem, still it might do so. I determined therefore to separate a nest before the young were born, or even the eggs laid, and then ascertain the result. Accordingly I took one of my nests, which I began watching on September 13, 1878, and which contained two queens, and on February 8, 1879, divided it into halves, which I will call A and B, so that there were approximately the same number of ants with a queen in each division. At this season, of course, the nest contained neither young nor even eggs. During April both queens began to lay eggs On July 20 I took a number of pupæ from each division and placed each lot in a separate glass, with two ants from the same division. On August 30 I took four ants from the pupæ bred in B, and one from those in A (which were not quite so forward), and after marking them as usual with paint, put the B ants into nest A, and the A ant into nest B They were received amicably and soon cleaned. Two, indeed, were once attacked for a few moments, but soon released On the other hand, I put two strangers into nest A, but they were at once killed. For facility of observation I placed each nest in a closed box. On the 31st I carefully examined the nests and also the boxes in which I had placed them I could only distinguish one of the marked ants, but there were no dead ants either in the nests or boxes, except the two strangers

Some further experiments led to similar results.

These observations seem to me conclusive as far as they go, and they are very surprising. In my experiments of last year, though the results were similar, still the ants experimented with had been brought up in the nest, and were only removed after they had become pupæ It might therefore be argued that the ants having nursed them as larvæ, recognised them when they came to maturity, and though this would certainly be in the highest degree improbable, it could not be said to be impossible. In the present case, however, the old ants had absolutely never seen the young ones until the moment when, some days after arriving at maturity, they were introduced into the nest, and yet in all ten cases they were undoubtedly recognised as belonging to the community

It seems to me therefore to be established by these experiments that the recognition of ants is not personal and individual, that their harmony is not due to the fact that each ant is individually acquainted with every other member of the community.

At the same time the fact that they recognise their friends even when intoxicated, and that they know the young born in their own nest even when they have been brought out of the chrysalis by strangers, seems to indicate that the recognition is not effected by means of any sign or password.

Worker breeding.—In my last paper I brought forward some strong evidence tending to show that when workers laid eggs they always produced males. This is, however, a physiological fact of so much interest that I have carefully watched my nests this year also, to see what further light they would throw on the subject. In six of those which contained no queen eggs were produced, which of course must necessarily have been laid by workers belonging to *Lasius niger*, *Formica cinerea*, *Formica fusca* and *Polyergus rufescens*.

The result was that in five of these nests males have been produced, and in not a single case has a worker laid eggs which have produced a female, either a queen or a worker. Perhaps I ought to add that workers are abundantly produced in those of my nests which possess a queen. Again, as in previous years, so this season again, while great numbers of workers and males have come to maturity in my nests, not a single queen has been produced. We have, I think, therefore, strong reason for concluding that, as in the case of bees, so also in ants, some special food is required to develop the female embryo into a queen.

As to Hearing and Experiments with Telephone.—In order to ascertain if possible whether ants made any sounds which were audible to one another, I thought I would try the telephone. Accordingly I looked for two ants' nests (*Lasius niger*) not far from one another, and then, after disturbing one of them, had a telephone held just over it. I then held the second telephone close over the other nest, each telephone being

perhaps one to two inches above the ground. If the disturbed ants made any sound which was transmitted by the telephone, the ants in the other nest ought to have been thrown into confusion. I could not, however, perceive that it made the slightest difference to them. I tried the experiment three or four times, always with the same result. I then put some syrup near a nest of *L. niger*, and when several hundred ants were feeding on the syrup I blew on the nest, which always disturbs them very much. They came out in large numbers and ran about in great excitement. I then held one end of the telephone over the nest, the other over the feeding ants, who, however, took not the slightest notice. I cannot, however, look on these experiments as at all conclusive, because it may well be that the plate of the telephone is too stiff to be set in vibration by any sounds which ants could produce.

On the Treatment of Aphides.—Our countryman Gould, whose excellent little work on ants[1] has hardly received the attention it deserves, observes that "the queen ant [he is speaking of *Lasius flavus*] lays three different sorts of eggs: the slave, female, and neutral. The two first are deposited in the spring, the last in July and part of August; or, if the summer be extremely favourable, perhaps a little sooner. The female eggs are covered with a thin black membrane, are oblong, and about the sixteenth or seventeenth part of an inch in length. The male eggs are of a more brown complexion, and usually laid in March."

Here however our worthy countryman fell into an error, the eggs which he thus describes not being those of ants, but, as Huber correctly observed, of Aphides.[2] The error is the more pardonable, because the ants treat these eggs exactly as if they were their own, guarding and tending them with the utmost care. I first met with them in February, 1876, and was much astonished, not being at that time aware of Huber's observations. I found, as Huber had done before me, that the ants took the greatest care of these eggs, carrying them off to the lower chambers with the utmost haste when the nest was disturbed. I brought some home with me and put them near one of my own nests, when the ants carried them inside. That year I was unable to carry my observations further. In 1877 I again procured some of the same eggs, and offered them to my ants, who carried them into the nest, and in the course of March I had the satisfaction of seeing them hatch into young Aphides. M. Huber however does not think these are mere ordinary eggs. On the contrary he agrees with Bonnet "that the insect, in a state nearly perfect, quits the body of its mother in that covering which shelters it from the cold in winter, and that it is not, as other germs are, in the egg surrounded by food, by means of which it is developed and supported. It is nothing more than an asylum of which the Aphides born at another season have no need; it is on this account some are produced naked, others enveloped in a covering. The mothers are not then truly oviparous, since their young are almost as perfect as they ever will be, in the asylum in which Nature has placed them at their birth."[3]

This is, I think, a mistake. This is not the opportunity to describe the anatomy of the Aphis; but I may observe that I have examined the female, and find these eggs to arise in the manner so well described by Huxley in our *Transactions*,[4] and which I have also myself observed in other Aphides and in allied genera.[5] Moreover I have opened the eggs themselves, and have also examined sections, and have satisfied myself that they are true eggs containing ordinary yelk. If examined while still in the ovary the germ-vesicle presents the usual appearance, but in laid eggs I was unable to detect it. So far from the young insect being "nearly perfect," and merely enveloped in a protective membrane, no limbs or internal organs are present. These bodies are indeed real ova, or pseudova, and the young Aphis does not develop in them until shortly before they are hatched.

When my eggs hatched I naturally thought that the Aphides belonged to one of the species usually found on the roots of plants in the nests of *Lasius flavus*. To my surprise, however, the young creatures made the best of their way out of the nest, and indeed were sometimes brought out by the ants themselves. In vain I tried them with roots of grass, &c.; they wandered uneasily about, and eventually died. Moreover they did not in any way resemble the subterranean species. In 1878 I again attempted to rear these young Aphides; but though I hatched a great many eggs, I did not succeed. This year however I have been more fortunate. The eggs commenced to hatch the first week in March. Near one of my nests of *Lasius flavus*, in which I had placed some of the eggs in question, was a glass containing living specimens of several species of plant commonly found on or around ants' nests. To this some of the young Aphides were brought by the ants. Shortly afterwards I observed on a plant of daisy, in the axils of the leaves, some small Aphides very much resembling those from my nest, though we had not actually traced them continuously. They seemed thriving, and remained stationary on the daisy. Moreover, whether they had sprung from the black eggs or not, the ants evidently valued them, for they built up a wall of earth round and over them. So things remained throughout the summer; but on October 9 I found that the Aphides had laid some eggs exactly resembling those found in the ants' nests; and on examining daisy-plants from outside I found on many of them similar Aphides, and more or less of the same eggs.

I confess these observations surprised me very much. The statements of Huber have not indeed attracted so much notice as many of the other interesting facts which he has recorded; because if Aphides are kept by ants in their nests, it seems only natural that their eggs should also occur. The above case however is much more remarkable. Here are Aphides, not living in the ants' nests, but outside, on the leaf-stalks of plants. The eggs are laid early in October on the food-plant of the insect. They are of no direct use to the ants, yet they are not left where they are laid, where they would be exposed to the severity of the weather and to innumerable dangers, but brought into their nests by the ants, and tended by them with the utmost care through the long winter months until the following March, when the young ones are brought out and again placed on the young shoots of the daisy. This seems to me a most remarkable case of prudence. Our ants may not perhaps lay up food for the winter, but they do more, for they keep during six months the eggs which will enable them to procure food during the following summer.

No doubt the fact that our European ants do not generally store up food in the usual way is greatly due to the nature of their food. They live, as we know, partly on insects and other small animals which cannot be kept fresh; and they have not learnt the art of building vessels for their honey, probably because they are not kept in cells like those of the honey-bee, and their pupæ do not construct firm cocoons like those of the humble-bee.

Moreover it is the less necessary for them to do so, because if they obtain access to any unusual store of honey, that which they swallow is only digested by degrees and as it is required; so that, as the camel does with water, they carry about with them in such cases a supply of food which may last them a considerable time. They have moreover, as we know, the power of regurgitating this food at any time, and so supplying the larvæ or less fortunate friends. Even in our English ants the quantity of food which can be thus stored up is considerable in proportion to the size of the insect; and if we watch, for instance, the little brown garden-ant (*Lasius niger*) ascending a tree to milk their Aphides, and compare them with those returning full of honey, we shall see a marked difference in size.

We have, indeed, no reason to suppose that in our English ants any particular individuals are specially told off to serve as receptacles of food. W. Wesmael, however, has described[1] a remarkable genus (*Myrmecocystus mexicanus*), brought by M. de Normann from Mexico, in which certain individuals in each nest serve as animated honey-pots. To them the foragers bring their supplies, and their whole duty seems to be to receive the honey, retain it, and redistribute it when required. Their abdomen becomes enormously distended, the intersegmental membranes being so much extended that the chitinous segments which alone are visible externally in ordinary ants seem like small brown transverse bars. The account of these most curious insects given by MM. de Normann and Wesmael has been fully confirmed by subsequent observers; as, for instance, by Lucas,[2] Saunders,[3] Edwards,[4] Blake,[5] Loew,[6] and McCook.

[1] "An Account of English Ants." By the Rev. W. Gould, 1747, p. 36.
[2] My lamented friend Mr. Smith also observed these eggs (*Entom. Annual*, 1871). He did not however identify the species to which they belonged.
[3] "The Natural History of Ants." By M. P. Huber, 1820, p. 246.

[4] *Proc.* Californian Academy, 1873.
[5] *Ibid.* 1874.
[6] *American Nat.* viii. 1874.

On one very important point, however, M Wesmael was in error; he states that the abdomen of these abnormal individuals "ne contient aucun organe; ou plutôt, il n'est lui-même qu'un vaste sac stomacal." Blake even asserts that "the intestine of the insect is not continued beyond the thorax," which must surely be a misprint; and also that there is no connection "between the intestine and the cloaca"! These statements, however, are entirely erroneous; and, as M. Forel has shown, the abdomen does really contain the usual organs, which, however, are very easily overlooked by the side of the gigantic stomach.

I have now the honour of exhibiting to the Society a second species of ant, which has been sent me by Mr Waller, in which a similar habit has been evolved and a similar modification has been produced. The two species, however, are very distinct, and the former is a native of Mexico, while the present comes from Adelaide in Australia. The two species, therefore, cannot be descended one from the other; and it seems inevitable that the modification has originated independently in the two species.

It is interesting that, although these specimens apparently never leave the nest, and have little use therefore for legs, mandibles, &c., the modifications which they have undergone seem almost confined to the abdominal portion of the digestive organs. The head and thorax, antennæ, jaws, legs, &c, differ but little from those of ordinary ants

CAMPONOTUS INFLATUS, n. sp

Operaria. Long 15 mill Nigra, tarsis pallidioribus, subtiliter coriacea, setis cinereo testaceis sparsis, antennis tibiisque haud pilosis, tarsis infra hirsutis; mandibulis punctatis, hirsutis, sexdentatis; clypeo non carinato, antice integro; petioli squama modice incrassata, antice convexa, postice plana emarginata

Hab. Australian.

The colour is black, the feet being somewhat paler The body is sparsely covered with stiff cinereo testaceous hairs, especially on the lower and anterior part of the head, the mandibles, and the posterior edge of the thorax. The head and thorax are finely coriaceous.

The antennæ are of moderate length, twelve-jointed, the scape about one-third as long as the terminal portion and somewhat bent At the apex of the scape are a few short spines, bifurcated at the point. At the apex of each of the succeeding segments are a few much less conspicuous spines, which decrease in size from the basal segments outwards. The antenna is also thickly clothed with short hairs, and especially towards the apex with leaf-shaped sense-hairs The clypeus is rounded, with a slightly developed median lobe and a row of stiff hairs round the anterior border, it is not carinated The mandibles have six teeth, those on one side being rather more developed and more pointed than those on the other. They decrease pretty regularly from the outside inwards. The maxillæ are formed on the usual type The maxillary palpi are six-jointed, the third segment being but slightly longer than the second, fourth, or fifth, while in *Myrmecocystus* the third and fourth are greatly elongated. The segments of the palpi have on the inner side a number of curious curved blunt hairs besides the usual shorter ones. The labial palpi are four-jointed. The eyes are elliptical and of moderate size The ocelli are not developed

The thorax is arched, broadest in front, without any marked incision between the meso- and metanotum, the mesonotum itself is, when seen from above, very broadly oval, almost circular, rather broader in front and somewhat flattened behind The legs are of moderate length, the hinder ones somewhat the longest The scale or knot is heart-shaped, flat behind, slightly arched in front, and with a few stiff, slightly diverging hairs at the upper angles. The length is about two thirds of an inch

ON THE THERMIC AND OPTIC BEHAVIOUR OF GASES UNDER THE INFLUENCE OF THE ELECTRIC DISCHARGE[1]

PROF. E. WIEDEMANN has undertaken an exact calorimetric investigation of the electric discharge through gases, and in spite of the serious difficulties which he had to encounter, he has already obtained valuable and important results. As a source of electricity, Topler's machine was used; but we must refer to the original paper for all details of experimentation.

Three series of observations were made. In the first the total heat generated in a given time in the whole vacuum tube was measured In the second series the capillary part only was examined, and in the third the thermal behaviour of the regions in the neighbourhood of the electrodes was investigated. The result of the first series is summed up as follows:—With decreasing pressure the total quantity of heat generated at first decreases, reaches a minimum, and then increases again. In hydrogen the amount of heat generated is smaller than in atmospheric air.

A smaller amount of heat developed corresponds to a larger number of discharges in a given time, and hence to a smaller potential at the moment the discharge begins to pass. The results of Prof Wiedemann are therefore, as he points out, in accordance with those of Messrs De La Rue and Hugo Muller, who found that the difference of potential necessary to cause a discharge passes through a minimum as the pressure decreases.

Somewhat more complicated results were obtained when an air-break was introduced into the circuit In that case the air-break determines the difference of potential necessary to produce a discharge; but if the whole quantity of electricity would pass suddenly when that potential has been reached, and before it has had time to sink, the amount of heat generated would be independent of the pressure in the vacuum tube. This however is not the case, but the result is intermediate between that obtained when no air break exists, and that which would be obtained on the above supposition

The following results were obtained in the experiments in which the capillary part of a vacuum tube only was introduced into the calorimeter —

1. The heating effect in capillary tubes at pressures above 1 mm is almost independent of the quantity of electricity passing with each discharge, and nearly proportional to the total amount of electricity which passes

2 The heating effect is almost the same whether the positive or negative electrode of the tube is connected with the machine (the other electrode being connected with the earth), although the number of discharges passing in a given time is different.

3 With decreasing pressure the heat generated decreases very rapidly without passing through a minimum

4 The heating effect is independent of the shape of the electrodes. Some results obtained by Prof G Wiedemann, who had found that in tubes of different widths the same amount of heat is generated by the same current, were confirmed.

Calorimetric measurements made near the electrodes showed

1 The heating effect near the positive electrode decreases with decreasing pressure rapidly At very low pressures a small increase is sometimes observed.

2. The heating effect near the negative electrode decreases first with decreasing pressure, and then increases rapidly

The heating effect near the positive electrode shows some anomalies when an air break is introduced, the amount of heat generated being considerably increased.

Some measurements were reduced to an absolute scale, and showed that the total amount of heat generated is very large Taking account of the number of discharges, and assuming that after each discharge the gas returns to its original state, the temperature in the capillary part of the tube must have been about 2,000° C at 15 mm pressure, and about 1,100° C at 5 mm pressure If the width of the tube was increased ten times, the temperature would only be about 100° C., and this confirms the result obtained by Prof. Wiedemann in a former investigation, that gases may become luminous under the influence of the electric discharge at a comparatively low temperature.

In another part of the paper Prof Wiedemann treats of a very important problem. When his tubes were filled with hydrogen, and an air-break was introduced in the circuit, the spectrum of the luminous gas changed suddenly at a given point According to a now generally accepted hypothesis this change of spectrum is always accompanied by a change in the molecular constitution of the gas, and it is to be expected therefore that heat is either absorbed or given out by a gas when its spectrum changes. This heat Prof Wiedemann has endeavoured to measure. Let us imagine, for instance, that the current has to do the work of decomposing the molecules of a gas The moment the discharge has passed, recomposition will take place, and the heat then generated was measured by Prof. Wiedemann. Some of the suppositions on which the calculations are based might require further investigation, but the assumptions made are supported, and to a certain extent proved by the fact that the heat necessary to change the band-spectrum into the line-spectrum was found to be *independent of the pressure and cross-section of the tube.* It is

[1] By Eilhard Wiedemann (*Wied. Ann*, x. p. 202.)

clear that Prof. Wiedemann's line of investigation would afford an absolute proof that the changes of spectra are really due to the causes to which they are now hypothetically referred by the majority of observers It is however rather unfortunate that in the particular case under discussion the chemical origin of the band-spectrum has not been settled to the general satisfaction of all observers A good many of them believe the spectrum to be due to a hydrocarbon, and in that case Prof Wiedemann would simply have measured the heat of combustion of hydrogen and carbon. No doubt Prof Wiedemann will extend his measurements to other gases for which the spectroscopic difficulties have been more satisfactorily settled

Prof. Wiedemann has also investigated some phenomena in vacuum tubes, which have also been partly discussed by other observers. Thus under certain conditions more exactly investigated by Messrs. Spottiswoode and Moulton, it is known that a conductor of electricity brought near a vacuum tube will deflect the discharge Prof. Wiedemann finds, as had already been previously noticed by Mr Goldstein, that the point touched by the conductor behaves like a negative electrode It is known that as a rule the rays proceeding from a negative electrode are propagated in straight lines, and do not turn round a corner An experiment however is mentioned by Prof Wiedemann, in which an exception to this rule seems to take place, but Prof Wiedemann himself suggests that secondary phenomena might have influenced the result Perhaps an explanation is to be found in the fact proved by Mr Goldstein, that when two tubes of different width are fused together the point of junction behaves like a negative electrode

Some experiments were made to show that the rays producing the phosphorescence can traverse the positive discharge; also to prove that when the pressure is very small the shape of the electrodes has a great influence on the number of discharges and on the other phenomena attending them

Prof. Wiedemann winds up with some interesting speculations on the nature of the discharge of electricity through gases, but it was our object to give an account only of his experimental results A theoretical discussion would lead us too far, as we should have to take account of other writings which have lately appeared. We may return to this part of the subject on another occasion. It is evident from the account we have given that the calorimetric methods employed by Prof Wiedemann have enabled him to take a very material step towards the elucidation of a difficult problem, and we may hope for another series of his valuable measurements. ARTHUR SCHUSTER

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

EDINBURGH —The Baxter Physical Science Scholarship of 116*l*, conferred by the University of Edinburgh on the most eminent B Sc who has taken his degree during the present or the preceding year, has been awarded to Mr D Orme Masson, lecturer on Chemistry at University College, Bristol, who is prevented from accepting it in consequence of holding his present appointment

THE system of Fellowships in the Johns Hopkins University is of considerable interest. Twenty Fellowships, each yielding five hundred dollars, are annually open to competition in this University. The system of Fellowships was instituted for the purpose of affording to young men of talent from any place an opportunity to continue their studies in the Johns Hopkins University, while looking forward to positions as professors, teachers, and investigators, or to other literary and scientific vocations The appointments have not been made as rewards for good work already done, but as aids and incentives to good work in the future; in other words, the Fellowships are not so much honours and prizes bestowed for past achievements, as helps to further progress, and stepping-stones to honourable intellectual careers. They have not been offered to those who are definitely looking forward to the practice of either of the three learned professions (though such persons have not been formally excluded from the competition), but have been bestowed almost exclusively on young men desirous of becoming teachers of science and literature, or determined to devote their lives to special branches of learning which lie outside of the ordinary studies of the lawyer, the physician, and the minister. Every candidate is expected to submit his college diploma or other certificate of proficiency from the institution where he has been taught, with recommendations from those who are qualified to speak of his character and attainments But this is only introductory. He must also submit, orally or in writing, such evidence of his past success in study and of his plans for the future, together with such examples of his literary or scientific work as will enable the professors to judge of his fitness for the post The examination is indeed in a certain sense competitive, but not with uniform tests, nor by formal questions and answers submitted to the candidates First, the head of a given department considers, with such counsel as he may command, the applicant's record The professors then collectively deliberate on the nominations made by individual members of their body The list upon which they agree, with the reasons for it, is finally submitted by the president of the University to the Executive Committee, and by them to the trustees for final registration and appointment By all these precautions the highest results which were anticipated have been secured A company of most promising students has been brought together, and their ability as teachers and scholars has been recognised by the calls they have received to permanent and attractive posts in different parts of the country

A SPECIAL feature of Russian universities is that the students mostly belong to the poorer classes, and that they earn the means of existence by teaching or by translating foreign works for the monthly reviews Thus, at the same time as the foundation stone of the Siberian University was laid at Tomsk, a subscription was raised for the erection of a building in which gratuitous lodgings might be given to students The well-known explorer of Western Siberia, M Yadrintzeff, immediately after his return from his last journey, delivered a series of lectures on the scenery of Altay, to raise funds for that purpose.

THE new university at Tomsk will be most liberally endowed Up to the day of laying the foundation-stone 354,000 roubles (about 53,000*l*.) had been received for the building, 100,000 roubles (15,000*l*.) for teaching utensils, and 31,000 roubles (4600*l*.) for stipendia A library of more than 35,000 volumes is ready, and only waiting the building of the necessary apartments to house it

SCIENTIFIC SERIALS

Trimen's Journal of Botany, October, 1880–January, 1881 —Among the more valuable articles in the most recent numbers of this journal may be mentioned —*Musci præteriti* (new or badly-described mosses), by R Spruce —An account of the Acanthaceæ of Dr Welwitsch's Angolan herbarium, by S Le M Moore, with descriptions of a number of new species —On *Manihot Glaziovii*, the plant affording Ceara india rubber, by Dr. Trimen.—On a collection of Madagascan ferns, by J G Baker —On *Chara obtusa* (*stelligera* Bauer), a species new to Britain, by H and J. Groves —The history of the scorpioid cyme, by Dr. S. H Vines —On the plants of North Aran Island, co Donegal, by H. C. Hart, with a number of interesting shorter notices and articles

Journal of the Royal Microscopical Society, vol iii No 6 for December, with special index number, contains—The Transactions of the Society —Charles Stewart, on some structural features of *Echinostrephus molaris*, *Parasalenia gratiosa*, and *Stomopneustes variolaris*, with plate 20 —Dr H Stolterfoth, on the diatomaceæ in the Llyn Arenig Bach deposit.—Dr G W. Royston-Pigott, on a new method of testing an object-glass used as a simultaneous condensing illuminator of brilliantly reflecting objects such as minute particles of quicksilver.—The record of current researches relating to invertebrata, cryptogamia, microscopy, &c —The year's journal forms a volume of over 1100 pages, of which less than 200 are filled with the Transactions of the Society, and over 800 with the increasingly useful record With the February number will commence a new series

SOCIETIES AND ACADEMIES

LONDON

Zoological Society, January 4.—Prof W. H. Flower, LL.D, F.R.S., president, in the chair —Mr. Sclater exhibited and made remarks on a skin of the Southern Merganser (*Mergus australis*) from the Auckland Islands, belonging to the collection of Baron Anatole von Hugel.—Prof A Newton, M.A, F.R.S., exhibited on behalf of Prof. Alphonse Milne-Edwards, F.M.Z.S., an egg of *Cariama cristata*, laid last summer in the Jardin des

Plantes, and possibly the first ever seen of which the parentage was certainly known, though an egg, also exhibited by Prof. Newton, had been for many years in the collection of Mr. H. F. Walter.—Dr. Albert Günther, F.R.S., read an account of the zoological collections made by Dr. R. W. Coppinger, R.N., during the survey of H.M.S. *Alert* in the Straits of Magellan and on the coast of Patagonia, and called attention to the most remarkable species represented in the various groups, which had been worked out by himself and his assistants in the Zoological Department of the British Museum. Dr. Günther also called attention to several interesting cases of the similarity of forms in these collections to known forms of the Arctic regions and of the Australian seas.—A communication was read from Prof. J. O. Westwood, containing the descriptions of some new exotic species of moths of the genera *Castnea* and *Saturnia*.—A second paper by Prof. Westwood contained observations on two Indian butterflies—*Papilio castor* and *P. pollux*.—Prof. W. H. Flower, F.R.S., described the skull of a very large elephant seal (*Macrorhinus leoninus*), lately received in the Museum of the College of Surgeons from the Falkland Islands, and discussed the questions of affinities and systematic position of this animal among the Pinnipeds. Prof. Flower arrived at the conclusion from an examination of its dental, cranial, and limb characters, and from some other points in its anatomy, that the elephant seal is the member of the group the farthest removed from the terrestrial carnivora and showing most cetacean analogies. He also considered that at present there is no evidence of the existence of more than one species of the genus.—Dr. A. Günther read some notes on the species of insectivorous mammals belonging to the genus *Rhynchocyon* and *Petrodromus*, and described two new species of the former genus, proposed to be called *R. macrurus* (from the Rovuma River), and *R. chrysopygus* (from the Mombaça River).

PARIS

Academy of Sciences, January 3.—M. Wurtz in the chair.—M. Jamin was elected Vice-President for 1881, and MM. Decaisne and Edm. Becquerel were elected Members of the Central Administrative Committee.—M. Becquerel gave information as to the Academy's publications, and the changes among members and correspondents. Two members have died during the year, M. Chasles and General Morin, and seven correspondents, MM. Borchardt, Peters, Lissajous, Favre, Miller, Schimper, and Mulsant.—The following papers were read:—On magnetic oxide of iron, by M. Berthelot. The heat liberated in fixation of oxygen by iron decreases (for a given quantity of oxygen) as we pass from the protoxide to the magnetic oxide, then to the peroxide.—Researches of M. Fournier on the fall of the barometer in cyclones, by M. Faye. M. Fournier gives a formula for the progress of the barometer, and shows its validity by observations at the Island of Réunion.—Mr. Gould was elected Correspondent in Astronomy, in room of the late M. Peters.—On observations of the satellites of Jupiter at Toulouse Observatory in 1879, by M. Baillaud.—On a process of astronomical observation for the use of voyagers, dispensing with the measurement of angles for determination of latitude and of sidereal time, by M. Rouget. This is by observing two stars that have at a given moment the same altitude, combining such observations in pairs, and noting the interval between the two phenomena, &c.—Determination of the lines of curvature of all the surfaces of the fourth class, correlatives of cyclides, which have the circle of infinity for double line, by M. Darboux.—Measurement of the electromotive force of batteries, by M. Baille. He uses a torsion balance having a long wire (2.70m.) of annealed silver, and a lever with balls of gilt copper at each end. Similar balls are fixed at the angles of a rectangle, and diagonal pairs are in communication with each other. The lever, placed at equal distance from the fixed balls, is connected through the torsion wire with the + pole of a battery, the other pole being to earth. One pole of the pile to be measured is connected with the fixed balls. The deflections are read by reflection of an illuminated glass scale. The apparatus is enclosed in a metallic case connected with the ground. A thick envelope of wood-shavings is used to exclude disturbances from heat.—On the velocity of light: reply to M. Cornu, by M. Gouy.—Study on spectrophotometers, by M. Crova. Two spectra from different sources may be easily compared by covering half the slit of a photometric spectroscope with a small rectangular prism, the edge of which cuts the slit normally into two equal parts; one half receives one of the lights directly, the other, by total reflection, the other light placed laterally. Aberration can be corrected with a cylindrical lens. The elliptic polarisation from total reflection may be suppressed, by replacing a simple prism by two total reflection prisms superposed in contact.—On a method of reproducing speech in electric condensers, and particularly in the singing condenser, by M. Dunand. He connects one pole of a battery with one end of the induced wire of the coil, the other pole with one armature of the condenser, while the second armature is attached to the other end of the induced wire. (In the circuit of the primary coil are a battery and carbon microphone). In this way speech may be reproduced with perfect distinctness. The condenser giving the best effects was 0.06m. in length of side; it contained thirty-six sheets of tin foil. For the auxiliary battery two or three (Leclanché) elements will give weak articulate sounds. The intensity increases with increase of the number of elements, but not proportionally. The current of the auxiliary coil does not traverse the condenser.—M. du Moncel made some remarks on the subject.—On the vapour-density of iodine, by MM. Crafts and Meier. They study the variation of the density with the tension and with the temperature. The facts agree with the hypothesis of progressive dissociation.—On the direct preparation of chlorised and bromised derivatives of the methylic series, and especially of chloroform and bromoform, by M. Damoiseau.—On the functions of the small oblique muscle of the eye in man, by M. Fano.—Facts for the study of formation of fogs, by M. André. This relates to a case in which a high barometer was observed to sink suddenly (with rain), while a fog present disappeared, with slow rise of the barometer the fog reappeared.—New eruption of Mauna-Loa (Hawaiian Islands), by Mr. Green. This was on November 9.—On the formation of a thin layer of ice on the sea observed at Smyrna during the winter of 1879, by M. Carpentin. A slight breeze seems to have driven the waters of the Guedyzé against the quays of Smyrna, and there formed a thin layer on the surface, which froze in a complete calm on a clear night.—On a new use of electricity, by M. Grandt. This is, propelling vessels. A steam-engine drives one or more electro-dynamic induction apparatuses; the current is sent through a voltameter; the gases are conducted to an orifice in the keel, and exploded by an induction spark, with propulsive effect.

NORTH AMERICAN PINNIPEDS

History of the North American Pinnipeds: a Monograph of the Walruses, Sea-Lions, Sea-Bears, and Seals of North America. By J. A. Allen, Assistant in the Museum of Comparative Zoology at Cambridge. (Washington: Government Press, 1880.)

THIS bulky octavo volume forms No. 12 of the miscellaneous publications of the Department of the Interior, United States Geological and Geographical Survey of the Territories, which is under the charge of F. V. Hayden. It is a most important contribution to the life-history of the species of American Pinnipeds, for which the zoologist as well as the merchant may well thank both Mr. Hayden and Mr. Allen.

It is not an easy task to analyse a closely-printed volume of nearly 800 pages, but still we trust to be able to give our readers some notion of the general contents of this interesting work. Of the mammals, leading an essentially aquatic existence, the furred and fin-footed group have always had an importance and interest for mankind. The existing Pinnipeds constitute three very distinct families: these are the Walruses, the Eared Seals, and the Earless Seals. The first two are far more nearly allied than are either of these with the third. The Earless Seal is the lowest or most generalised group. The Walruses are really little more than thick clumsy fat forms of the Eared Seal group, with immensely developed canine teeth, and skulls modified so as to bear these. All the Pinnipeds have a high degree of brain development, and are easily domesticated under favourable conditions; they manifest strong social and parental affections, and they defend their young with great courage. They are, almost without exception, carnivorous, mostly feeding on fish, mollusks, and crustacea. While the Eared Seals are polygamous, the males greatly exceeding the females in size, the Walruses and the Earless Seals are thought to be monogamous, and there is very little difference between the size of the sexes. The polygamous species usually resort in large numbers to favourite breeding-grounds, the young are born on dry ground, and are at first unable to swim; while the monogamous forms do not so uniformly resort to particular breeding-grounds on land, and they leave the water only for short intervals. As a group the Pinnipeds are very distinctly characteristic of the Arctic, Antarctic, and temperate portions of the globe; very few range into tropical waters, and only one species can be said to be strictly tropical. While the Seals, Eared and Earless, are abundantly represented on both sides of the Equator, the Walruses are only to be found within the colder portions of the Northern Hemisphere. Of the family of the Walruses but two living species belonging to the genus Odobænus are known, the one, *O. rosmarus*, being the Atlantic Walrus; the other, *O. obesus*, the Pacific Walrus. The history of both species is here given at length: first a full synonymy is given; then the general history, accompanied by figures; then habits, products, food, and enemies. Among the figures given are those of Elliott of the head of the Pacific species, which give an idea of the uncouth facial aspect and of the strangely-wrinkled skin; but it is a pity that none of Elliott's representations of an adult form were reproduced from his work on Alaska, published in 1879, and of which only one hundred and twenty-five copies were printed. Capt. Cook's description of this species is still one of the best extant—a species that may soon disappear if the annual slaughter of ten to twelve thousand animals is allowed to continue.

The number of genera and species among the group of the Eared Seals has fluctuated immensely even within the last ten years. The views of Gray and Peters have repeatedly changed on this subject, "greatly," the author writes, "in the case of Gray, out of proportion to the new material he had examined." In Peters' latest enumeration he gives thirteen species: five are Hair Seals, or Sea-lions, eight are Fur Seals, or Sea-bears. Mr. Allen enumerates nine—two with doubt. Five are Hair and four Fur Seals. A good deal of this discrepancy doubtless arose from writers not having learnt to distinguish the sexes, and from their not making due allowance for the great changes in contour and details of structure that result in the skulls of these animals from age. The most striking fact in respect of the distribution of the Eared Seals is their entire absence from the waters of the North Atlantic. The Fur and Hair Seals have nearly the same geographical distribution; but though commonly found frequenting the same shores, they generally live apart. They are about equally and similarly represented on both sides of the equator, but are confined almost wholly to the temperate and colder latitudes. The Hair Seals have coarse hard stiff hair, and are wholly without soft under-fur, the abundant presence of which in the Fur Seals it is which makes their skins so valuable as articles of commerce.

The Eared Seals are all gregarious and polygamous. Their breeding-places have received the strangely inappropriate name of "rookeries." The strongest males generally secure to their lot from twelve to fifteen females. During the breeding season the males remain wholly on land, and they will suffer death rather than stir from their chosen spot. They thus sustain for a period of several weeks a continual fast. Steller's account, given nearly a century ago, applies still to nearly all the species. The "sea-fur" of the furriers is obtained from these Eared Seals with the under-fur. Fortunately the destruction of the Fur Seals at the Aleutian Islands, where at one time these seals were killed at the rate of 200,000 a year, has now been placed under rigid restrictions, and the same systematic protection ought to be afforded to them at all their stations. In 1877 Mr. Elliott calculated that the number—owing to the Government regulations—of Seals on the Alaska Islands had increased so as to leave 660,000 breeding females to be added to the original stock, and that the total number would not be much less than 1,800,000.

The description of the Earless Seals forms nearly one half of the volume. The technical history of the group is given at length and is most interesting. The genus Phoca of Linneus embraced four species now placed in four distinct genera and in three families. Since then 103 distinct specific and varietal names have been bestowed upon what our author considers as sixteen species. These are located in three sub-families and placed in

eleven genera. Copious synonymic details are given Of the restricted genus Phoca, three—*P. vitulina*, *P. Groenlandica*, and *P. fœtida*—are marine, and frequent the northern oceans, never descending anywhere near to the equator. A fourth, *P. Caspica*, is found in the Aral and Caspian Seas, and a fifth, *P. Sibirica*, is from Lakes Baikel and Oron. *Monachus albiventer* occupies an intermediate position (Mediterranean, Madras, and Canary Islands) between these northern forms and the Antarctic species, such as *Macrorhinus leoninus*, *Ogmorrhinus leptonyx*, *Ommatophoca rossi*, and the like. All the species have strong social instincts, and are almost unsurpassed in their affection for their young Most of them are gregarious; few of them are in the least ferocious, they are in general patient and submissive creatures, quite harmless to man. Fond of basking in sunshine, they spend a good deal of their time out of the water, on bank, rock, or ice. They are very voracious, eating fishes, or in lack of these, mollusks and crustacea. Strange though it may seem, the young seals take to the water reluctantly, and have to be actually taught to swim by their parents The young of some species remain on the ice until they are from two to three weeks old, or until they have shed their first soft woolly coat of hair; their cry is more of a bark than a roar, that of the young is a kind of tender bleat, putting one in mind of the cry of a young child Dr. Murie (*Proc* Zool Soc London, 1870) has characterised three distinct modes of terrestrial locomotion among these Seals, from which it would appear that the Phocine Seals generally have considerable power of movement upon land

The Seal-hunting districts are described at length, the oil and skins of these Seals having a large commercial importance The Dundee sealers took in 1876 nearly 40,000*l* worth. The habits of the various species form a most interesting portion of this division of the volume, and the author seems to have ransacked every treatise on the subject so as to make his own complete. This history of the North American Pinnipeds will long remain a perfect monograph of a valuable and important group of mammalia.

CATALOGUE OF NEWCASTLE LIBRARIES

Newcastle-upon-Tyne Public Libraries. Catalogue of the Books in the Central Lending Department Compiled by W. John Haggeston, Chief Librarian. (Newcastle-upon-Tyne: 1880)

NO portion of a book draws more heartfelt commendation or more earnest rebuke from a critic who has read it, not for the purpose of criticising, but for that of using its information, than the index. Only the reader who picks up a book for recreation and amusement feels at all independent of it; and even he appreciates its importance if any future reference is required. And if a good table of contents is so requisite in the case of a single book, how far more so must one be in a large library.

We have here a new catalogue of a new library, a selection of 20,000 volumes of books chosen for their readable value only (which perhaps justifies the omission of all dates of publication of the books, which would be a fault in a catalogue of most libraries), and consequently we may look to it as a model of what a catalogue should be. And we shall not be disappointed. It is drawn up on the same scientific principles worked out so fully in Dr. Billing's catalogue of the U.S. Surgeon-General's Office, which we noticed lately, and these so well worked out too, that really it is a table of contents of the library; the matter contained in the volumes of the latter as well as their titles are all laid before us. Each work is entered under the author's name, under the title, and, in cases where that title is compound, under each of the subjects it may include Under the heading of each principal subject treated a reference is again given to the work with its library number, and so numerous are these cross references that on an average every volume throughout the library appears four times over. Indefinite titles are rectified by a summary being given, in a smaller type, of the matters discussed

Catalogues which limit themselves rigidly to the contents of the title-page abandon all attempts at completeness, since many titles do not even pretend to express the subjects of the book (need we cite Mr. Ruskin's?), and many equally fail in the attempt As the field of literature increases, and not even a librarian can keep himself acquainted with the ground gone over by all the books under his care, a subject-catalogue as well as an author- and title-catalogue becomes a necessity, and, if it is well drawn up, though it may cost both money and time, they will be well spent Volumes that appear unattractive enough to the general reader, and are far too numerous for the ordinary student to search through, become suddenly, through a subject-catalogue, of the greatest value to both of them The books in a library whose contents are thus laid open to its frequenters will be read with profit much greater than would a considerable fraction more books whose title-page was all the introduction their readers had to them.

And the saving of time when it is completed will be immense It will save the time of the librarian by preventing hundreds of inquiries being made at all, and still more by strengthening the hands of his assistants, who will be capable of working his catalogue to the utmost and answering a very large proportion of such inquiries as are made by readers who may be awkward at it, it will save the time of the busy man, who wants his information at once, it will save the time of the student who wants the most recent information which he can get, and it will save the time of all by making fewer changes of books necessary.

All this is doubly important in a Free Library, because, as any one taking an interest in these institutions will have marked, those of its readers who do not confine themselves to novels seldom take out books for the mere pleasure of reading, as the higher classes do Reading has not yet become a recreation to them, but they go to the library as to a great encyclopædia to get information on certain subjects, often of the most technical character, and a catalogue that directs them to the very book they want doubles and trebles the value of the library to them. They have no time to read all the *critiques* and *résumés* of new books with which the press teems, and which make the style and contents of many such works familiar to readers of periodicals who may never have seen the works

themselves. Where hundreds go in an evening for books it is impracticable to allow them access to the shelves of the library to select them, while in an ordinary bare list of titles it is impossible for them to judge which book in a column will be found the one most to their requirements

Like Dr Billings, our Newcastle librarian has fully worked out a most important branch of a subject-catalogue Magazine literature in these days has become far too important to be treated by either a thrifty librarian or an inquiring student as "fugitive" and "ephemeral." All the newest science now appears first in journals, and all leaders of thought give their first expression of it in magazines and reviews. In this new catalogue therefore we are much pleased to see that not only is each volume of all important periodicals entered separately with its list of articles, but, as we have said, under the head of each subject a reference is given to all of such articles as bear upon it. By this means students who have read a standard work published a few years ago upon any subject will be not only guided but stimulated into reading the latest researches or theories which these publications contain It is perhaps going beyond our subject, but we cannot help noticing how convenient for this important purpose a card-catalogue at a library is, in which cards containing the subject of each article down to the last number of all the magazines have been dropped into their places Such an arrangement would make many students feel a printed catalogue to be ancient by the time it was published

The selection of books as a whole is admirable—though of course few selections have been made under such favourable circumstances We are rather surprised in so large a list to note the absence of books like Boyd Dawkins's "Cave-Hunting" and "Early Man in Britain," Clifford's "Lectures and Essays," Croll's "Climate and Time," Moseley's "Naturalist on board the *Challenger*," and Sir Wyville Thomson's book; Hæckel's "History of Creation" and "Evolution of Man", Schliemann's "Troy" and Cesnola's "Cyprus", Wallace's "Geographical Distribution of Animals," &c. And if some of these are so costly as to be confined to the Reference Library, as is probably the case here, still we are sorry to miss Wallace's "Tropical Nature," and R. Jefferies ("The Gamekeeper at Home") with his series of books teaching men to open their eyes as they move about the fields and lanes.

The printing is a credit to both printer and editor It is almost as funny as the "Ingoldsby Legends" to read "Life and Remains of *Dean* Hook," by Barham! but it is plainly a slip, and the smallest errors are very scattered.

The Rules and Regulations are clumsy to enforce, which indeed will probably not be attempted, at any rate for long. The annoyance of having to get a guarantor practically shuts out many whose hitherto idle life might have taken a fresh start if books had been put into their hands freely. We have been very pleased to see that several large libraries have done away with this irritating system without any loss of property, and it seems a step backwards when a new institution like this starts with more rigid and inconvenient rules than many others. Indicators are capital things in libraries to which each reader goes for his own book as at a university, but only very few of the hundreds who exchange books every night at a flourishing Free Library are at all able to work with them. Children are the usual messengers, not high enough to consult an Indicator of 20,000 volumes It is an unmerciful rule that borrowers should return their books personally, and a downright unreasonable one that every book must be returned in a fortnight (Rule 17), NOT to be re-issued the same day (Rule 16), although we are told (p. vi) that three-volume works are issued complete Few Free Library readers can get through 600 or 800 pages in a fortnight. And surely it was not necessary to threaten each person who consults the catalogue with imprisonment *with whipping* if he defaces a book! It may be necessary to make such Draconian laws, but they should be brought forward to intimidate gross offenders, not flourished in the face of all whom we wish to attract. Such severe rules repel sensitive people, while from their very familiarity they lose their effect on the careless

OUR BOOK SHELF

Botanische Jahrbucher fur Systematik Pflanzengeschichte und Pflanzengeographie Herausgegeben von A Engler Erster Band, zweites Heft (Leipzig Wilhelm Engelmann, 1880)

THIS part includes four papers. The first is by W O Focke, on the natural divisions and geographical distribution of the genus Rubus The characters chiefly discussed are —1 Mode of growth or habit. 2 Forms of leaf which are very numerous the duration of the leaf being also variable. 3 Characters derived from the stipules, which are considered of great value 4. Inflorescence, and 5 the Structure of the flower The number and size of the parts of the calyx and corolla vary, as also the colour of the corolla The stamens vary in closely allied species, and while most of the species are hermaphrodite, some are unisexual The structure of the gynæcium is very varied, the number of carpels being five or six in some, as in *R. dalibarda*, or above 100, as in *R rosæfolius* The hairs (trichomes) on the different parts of the plant are very numerous and remarkable for the variety of structure shown, no other group, except perhaps some Solanaceæ, approaching the Rubi in this particular In regard to the geographical distribution the most important points are —1 The characteristic difference in the Rubi of Eastern Asia and Europe. 2 The predominance of European forms in the Atlantic, and of East Asian forms on the Pacific side of America 3 The occurrence of south Chinese and north Indian types in Mexico and Peru These peculiarities Focke would explain on geological grounds

The second paper is by Franz Buchenau on the distribution of Juncaceæ over the world The author gives a complete list of the species of the genera Juncus Luzula, Rostkovia, Marsippospermum, Oxychloe, Distichia, and Prionium, and a table showing their distribution into regions nearly corresponding to those of Grisebach.

Koehne, in the third paper, gives the first portion of a monograph of the Lythraceæ, including a key to twenty-one genera. He admits and then describes thirty-one species with numerous varieties of Rotala (Ammania, Linn, Benth., and Hooker)

The last paper is by Engler Contributions to the knowledge of the Araceæ, in which he describes some new Araceæ from the Indian Archipelago and Madagascar, and also directs attention to the cultivation of *Zamioculcas Loddigesii* from the detached leaflets of the remarkable pinnate leaf of the plant. A swelling occurs at the base of the leaflet, and in a few days a small tuber is produced which develops two buds, below each of which roots are formed The plant has been propagated in this way by Herr Hild of the Kiel Botanic Garden.

The Fishes of Great Britain and Ireland By Dr. Francis Day, F L S, &c. (London. Williams and Norgate, 1880.)

THIS work is to be issued in nine parts, of which the first, containing sixty-four pages of text and twenty-seven plates, is now published. Waiting until the completion of the work for a more extended notice, we may for the present mention that in it the author purposes to give a natural history of the fishes known to inhabit the seas and fresh waters of the British Isles, with remarks on their economic uses and on the various modes of their capture, and that an introduction to the study of fishes in general is promised.

The synonymic lists of the species are given in great detail, the descriptive diagnoses treat of internal peculiarities as well as of external form, a good many interesting details appear under the headings of Habits, Means of Capture, Baits, Uses The plates are from drawings by the author, and are very excellent

A Manual of the Infusoria By W Saville Kent, F L S. (London David Bogue, 1880)

THIS sometime promised work has now advanced so far in its publication as the third part, when completed it will merit a somewhat lengthened notice, as the most important work on the subject which has issued from the British press It is intended to include a description of all known flagellate, ciliate, and tentaculiferous Protózoa, British and foreign, and an account of the organisation and affinities of the Sponges Each part (roy 8vo in size) contains over 140 pages and eight plates. The general get-up of the work is magnificent, rather too much so for the poor student, already weighed down by the burden of the parts of Stein's "Infusionsthiere," but very pleasant for the book fancier, and forming an imposing shrine wherein to inclose the records of these early-life forms

The first five chapters (pp 1-194) are introductory, treating of the general history of the group on the subkingdom Protozoa, on the nature and organisation of the Infusoria, on spontaneous generation, on the nature and affinities of the sponges The sixth chapter treats of the systems of classifications of the Infusoria, adopted by various authorities, from the time of O F. Muller to the present date The seventh chapter commences the systematic description of the Flagellata The third part, just published, carries the work as far as the 432nd page and to the twenty-fourth plate

A Complete Course of Problems in Practical Plane Geometry with an Introduction to Elementary Solid Geometry A New, Revised, and Enlarged Edition By J W. Palliser (London Simpkin, Marshall, and Co, 1881.)

THIS is a cheap manual, the cost of which can be easily met by any artisan desirous of studying the subject, while at the same time its contents enable it to fully satisfy the wants of all examinees in first, second, and third grade and similar papers of the Science and Art Department Examinations The figures are very clearly drawn, well showing given, constructional and required lines, the form of the page enables four propositions to be fully treated of with the accompanying figures in four spaces on each page. In the constructions we do not look for novelty, but we have conciseness and great clearness generally prevailing. Here and there elegance of expression is sacrificed to brevity ("for all the Government examinations, the requirements of which this is a text-book, the same rules will apply, with exception of Nos. 1 and 6") We have detected only three points which call for our notice in Prop. 12 it strikes us as being simpler to use the same radius throughout, thus doing away with the necessity of taking two cases, as Mr. Palliser does; in Prop. 37, *note*, it is necessary to add *how* the point is obtained; in Prop. 212 the letter E is made to do double duty in the proof. We can confidently recommend the book

Bericht über die Thätigkeit der Botanischen Section der Schlesischen Gesellschaft im Jahr 1877. Erstattet von Prof Dr Ferdinand Cohn

MOST of the papers in this part are in abstract; a few however are given at some length, and are of considerable interest The additions to the phanerogamous Flora of Silesia and the record of new localities for rare plants occupy a considerable part of the pamphlet Perhaps the most interesting paper is that on the Date-palm and Palm-forest at Elche in Spain, by General von Schweinitz The palms there grow to a height of from seventy-five to eighty feet The plants grow for about 100 years, then become stationary, and next decay. Each tree bears from the fifth year two to five bunches of fruit, each with from 500 to 600 dates, the weight of dates yielded by one tree being sometimes three centners Many of the papers in this part are contributed by Goeppert and Cohn, and deal with all departments of botany Dr Thalheim describes a series of models of diatoms made in paraffin and glycerine soap, which exhibited the structure of all the chief groups of this order of plants

LETTERS TO THE EDITOR

[The Editor does not hold himself responsible for opinions expressed by his correspondents Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications

The Editor urgently requests correspondents to keep their letters as short as possible. The pressure on his space is so great that it is impossible otherwise to ensure the appearance even of communications containing interesting and novel facts.]

Dr. Carnelley's Hot Ice

THE remarkable observation made by Dr. Carnelley that ice in a vacuum is very permanent, even though surrounded by and apparently in contact with very hot bodies, has caused him to suppose and maintain that the ice itself is at a high temperature, a supposition which has been apparently confirmed by preliminary calorimetric determinations. This proposition has naturally met with a good deal of scepticism, and certainly requires ample and cautious verification, but I venture to think that there is nothing in it contradictory to our present knowledge of the properties of matter, though if verified (as, for the reasons to be stated, I fully believe it will be) it constitutes an important addition to that knowledge.

The notions which have occurred to me have made the essential part of the phenomenon so much clearer to myself that I fancy they will not be uninteresting to your readers

By the term "vapour-tension" at a given temperature I mean, as I believe is usual, the pressure at which a liquid and a vapour can exist permanently together at that temperature, or the maximum pressure which the vapour is able to exert at that temperature, or the vapour pressure under which a liquid ceases to evaporate, or the total pressure at which it begins to boil By the term "boiling-point" I mean the temperature of a liquid under a total pressure equal to its vapour-tension.

Now in order that a solid may sublime or pass directly into the vaporous condition without melting, it must be either at a temperature below the melting-point, so that no liquid attempts to form, or else at such a temperature that any liquid formed shall instantly evaporate; which it would certainly do if it were above the boiling-point, that is if the total pressure on it were less than the vapour tension

A solid, under either of these circumstances, gives off vapour from its free surface at a rate depending on, but not necessarily proportional to, the supply of heat; for there is no definite subliming point for a solid, any more than there is a definite evaporating point for a liquid, so that the temperature of the solid need not remain constant. When a liquid is evaporating, the more you heat it the faster it evaporates, but not at a compensating rate, and the temperature rises as well: if this be true for a liquid, much more will it be true for a solid, whose

evaporation is always more encumbered, partly, no doubt, because its evaporating surface is a fixture. The only limit to the rise of temperature of a liquid is its boiling, but if this be prevented it may get superheated, and, unless the solid boil (*i.e.* disintegrate internally) it can become superheated to any extent. The possibility of this internal disintegration we will examine directly, but at present we will consider it practically *nil*.

Let us grant then that a subliming solid always rises in temperature if heated at a sufficient rate, and Dr. Carnelley's proposition follows.

We have seen that no liquid can exist at temperatures below its freezing- or above its boiling point, so that if we wish to prevent the possibility of its existence, we need only make these two points coincide. This can always be done by diminishing the pressure, for the boiling-point of all substances is greatly affected by changes of pressure, while the freezing-point is only slightly altered, and even, in the case of ice, in the opposite direction.

Start then with the solid below its melting-point, and reduce the pressure on it till the boiling point coincides with, or passes below the melting point. There is now no region where liquid can exist, and the solid must therefore sublime, but, by our supposition, a subliming solid if heated will get hot, hence the solid may now assume any temperature you please, and the hotter it gets the more pressure may be brought to bear upon it without causing it to melt, *i.e.* the pressure may be allowed to increase to anything short of the vapour tension at the new temperature. If heated sufficiently, then the whole atmospheric pressure may be let in, and no melting will occur. All that is necessary is that heat shall be supplied at a sufficient rate to compensate for the rapid evaporation (which however will not be so rapid as in the vacuum), and to prevent its temperature falling to the boiling-point, for if it reached this, part (or all) would quickly liquefy, and the whole fall to (or towards) the melting point.

Thus we have the remarkable proposition that if, by the process of lowering the boiling-point to coincide with or pass below the melting-point, we manage to get ice across the gap which ordinarily separates these two points, it may be heated to 120° or to any other temperature, and that when at 120° it will be permanent, and will not melt even under the whole pressure of the atmosphere. To prevent its melting you must keep on heating it: if allowed to cool to 100°, five-eighths of it will be instantly crushed to water, and the whole will be at 0° (assuming, what is not likely to be correct, that the specific heat of hot ice is ½).

There is still the question of the possibility of internal melting or sublimation to be considered.

Now I suppose that if a solid is perfectly homogeneous, a change of state in its interior would with great difficulty occur, and the solid might readily be superheated. But an excess of pressure at any point, such as would be produced by a bubble of air, would readily determine a melting-centre. In Prof. Tyndall's ice-flower experiment the nuclei are probably minute bubbles of air, and the ice walls of the cavities so produced are subject to the pressure of this air in addition to that of the vapour, and accordingly melting sets in and spreads. But Dr. Carnelley's ice is formed *in vacuo*, so that no air bubbles are possible, and the only nuclei that can properly exist are little bubbles of enclosed vapour, and these, I imagine, can scarcely be absent. Let us inquire then what can happen in the case of one of these bubbles when the temperature of the ice is raised either by radiation or conduction. Initially, while the temperature is constant, the vapour is saturated; but no liquid is formed because this temperature is below the melting-point. When heat is applied, the ice, being less diathermanous than the vapour, will get heated first, and so long as the temperature keeps rising it will always be a little hotter than the vapour, which consequently is not quite saturated, and the pressure it exerts is less than the "vapour-tension" (*i.e.* the temperature is above the boiling point), and no water can be formed. The cavity will of course enlarge by sublimation, but very slowly, much more slowly in fact than outside, if a vacuum is there artificially maintained.

But if cooling be permitted the ice will cool the fastest; and the vapour at once becomes over-saturated and condenses. The temperature is now below the boiling point, and liquefaction instantly sets in and rapidly spreads, the ice consuming its own heat in the process.

Internal disintegration therefore will not occur while the temperature is rising, but it will set in at a great pace if it be allowed to become stationary or to fall, unless there be an utter absence of nuclei. If the temperature rises very high the pressure of the internal vapour will of course be great, and ultimately might even be able to burst the ice, but this would scarcely occur under several atmospheres.

It would be interesting if Dr. Carnelley would kindly try the following experiments:—

1. Heat ice *in vacuo* with a pressure gauge, and, still heating it, stop the passage to the condenser so that the pressure is allowed to accumulate, and note the pressure and temperature when collapse occurs.

2. Heat ice up to any temperature, and, still maintaining a good vacuum, remove the supply of heat, and see if the ice does not collapse.

3. Heat the ice up to 120°, and, still heating it, let in the atmosphere gently (but make the air come in through hot pipes, or it will melt the ice), and see if the ice does not last rather longer than it would have done in the vacuum, because the evaporation will be more obstructed. But if the second experiment succeed, the temperature must never be allowed to fall much or to remain stationary long.

Finally, it is important to point out explicitly that the Carnelley experiment has no bearing on the change of the melting-point of ice with pressure. Our knowledge on this point remains as it was, viz. that the value of $\frac{d\theta}{dp}$ about zero centigrade is $-\cdot0071$, that is to say, the melting-point rises and falls about $\cdot0071°$ centigrade per atmosphere of pressure decrease or increase.

Of course this number is not absolutely constant, but its variation with pressure is very slight, and moreover has no bearing on the Carnelley experiment, as was naturally but erroneously supposed by Prof. Pettersson in the *Berichte* (18), and I believe also by Prof. Ayrton at the Chemical Society, though I had not the pleasure of hearing his remarks.

University College, London OLIVER J. LODGE

Note.—With reference to the above second experiment and the reasoning which suggested it, it is important to remark that I have all along assumed that the vapour tension of ice at any temperature is precisely the same as that of water at the same temperature. But Prof. Foster considers it possible that the vapour tension of ice may be less than that of water, and would hence explain the permanence of vapour inside an ice-cavity without attending to whether the temperature were rising or falling, provided it were not falling too fast. This would be a most important fact to discover and verify, but I think the Carnelley experiment in its present form does not inform us concerning its truth or falsity.

Another thing it may be interesting to note is the rate of variation of boiling-point with pressure at different temperatures, which can be calculated on thermodynamic principles (after Prof. James Thomson) from empirical data for the latent heat of steam, and for the density of saturated steam at any temperature.

It is, at the temperature θ and the pressure p,—

$$\frac{d\theta}{dp} = \frac{\theta^2}{273 \times 1\cdot008 \times (796\cdot2 - \cdot695\,\theta)/p}$$

a fraction which has the value 28 at 100° C., and 2180 at 0° C.: these numbers represent the rate of rise or fall of boiling point in centigrade degrees per atmosphere increase or decrease.

Integrating this equation, we get the value of the vapour-tension p of water in atmospheres (megadynes per square centimetre) at any absolute temperature θ, viz.—

$$\log p = 9\cdot1728 \left\{ \cdot695 \log \frac{373}{\theta} + 796\cdot2 \left(\frac{1}{373} - \frac{1}{\theta} \right) \right\},$$

the logarithms being to the base *e*.

On the Spectrum of Carbon

I HAVE a great respect for Dr. Watts's spectroscopic work, nevertheless the experiments he has described in NATURE, vol. xxiii. p. 197, appear to me singularly inconclusive for the purpose for which he has adduced them. How could any one expect to get a tube of gas free from hydrocarbons when the joints were of india rubber and melted paraffin? I have long since found it necessary to forego rubber joints if I would exclude hydrogen. Salet has shown that the hydrocarbons from the blowpipe flame used in sealing in wires, &c., and the last traces of dust, can only be removed from tubes by burning them out in a current of oxygen. But more than this, I have found

that even with joints all made by fusion of the glass it was well nigh impossible to get rid entirely of hydrogen. Mr Crookes has, I believe, found that the last traces of moisture adhering to glass can only be expelled by heating to the softening point of the glass. This tallies with my own experience. In a series of experiments on the ultra-violet water spectrum I had occasion to photograph the spectra of sparks in sundry gases wet and dry, and found that in gases which had been passed through a tube full of phosphoric anhydride the water-spectrum still appeared strongly. Even when the gas had been passed very slowly through two tubes each half a meter long filled with calcium chloride, and then through a similar tube full of phosphoric anhydride, and the part of the tube where the wires were sealed had been heated strongly for a long time, while the current of gas was passing, traces of the water spectrum still often appeared. But Dr Watts did not see the hydrogen lines in his tube My difficulty has always been to avoid seeing them when the pressure of the gas was sufficiently reduced and a large condenser used with the induction coil. True: tubes of gas may not always show them even when hydrogen is known to be present The spark takes a selected course of its own, and does not always light up all that is in the tube Carbonic oxide does not generally show oxygen lines, and in tubes exhausted by a Sprengel pump the lines of mercury do not usually appear until the pumping has been carried far. A real test would be to see whether when the spark gives the line-spectrum of carbon the hydrogen lines do not also appear. The experiment with naphthaline Prof. Dewar and I have repeated and discussed elsewhere, so I will say no more on it than this, that purity in regard to chemicals is a relative rather than an absolute quality, and that it is only from a long series of experiments chosen with a view to eliminate the effects of accidents of all kinds that any safe induction in this kind of spectroscopy can be reached

Cambridge, January 4 G D LIVEING

[To save time we submitted Prof Liveing's letter to Mr Watts, who sends the following reply —ED]

I SEE no reason why india-rubber stoppers may not be used in the construction of an apparatus to be filled with a gas *at atmospheric pressure*, or nearly so The case would be altogether different if we were concerned with the construction of a vacuum tube, and I take it that most of these statements of the difficulty of getting rid of the last traces of moisture and of hydrocarbons adhering to the glass refer to cases where the pressure is to be only a few millimetres But when a current of cyanogen at atmospheric pressure, made from dried mercuric cyanide, is passed through a U-tube filled with phosphoric anhydride, the gas is surely dry to all intents and purposes (I do not say that the glass would not give off traces of moisture, &c , if the pressure were to be reduced to an extreme point) , at least there can be so little hydrogen present in the tube that to ascribe the spectrum given by the tube to the hydrogen present in it is to adopt an extreme hypothesis, which must be supported by cogent experimental evidence before it can be accepted.

But if the defect of the experiment be in the use of india-rubber there can be no great difficulty in constructing the apparatus entirely of glass, and if we are to give up the view that the groups δ (5165 to 5082) and γ (5635 to 5478) are due to carbon, it must be shown that they are not present in the spectrum of the spark in cyanogen at atmospheric pressure when sufficient precautions are taken to obtain the gas pure. I have never examined the spectrum of the spark in cyanogen without seeing them, and have every confidence that Prof Liveing will still find them there after he has taken all the precautions he may think necessary.

But admitting for the sake of argument the justice of Prof. Liveing's contention that the cyanogen in my experiment contained a trace of hydrogen and that the naphthalin contained a trace of nitrogen, then this seems to be the theory offered for our acceptance—that the spark in nitrocarbon gas containing a trace of hydrogen gives the lines of hydrocarbon, and that the spark in hydrocarbon gas containing a trace of nitrogen gives the lines of nitrocarbon. Does Prof Liveing hold *both* of these hypotheses to be reasonable ? W. M. WATTS

Geological Climates

THE letter of Prof. Haughton in last week's NATURE so bristles with figures and calculations that some of your readers may feel a little puzzled and may be unable to detect the fallacies that lurk among them. The question is far too large a one to be fully discussed in your columns. I shall therefore confine myself to pointing out the erroneous assumptions and false inferences which vitiate all the learned Professor's calculations, having done which my own theory will remain, so far, intact.

The whole argument against me is based upon an "ideal ice-cap," extending from the Pole to lat 60°. A considerable but unknown thickness is given to this imaginary field of ice, and it is then calculated that the three great ocean streams, even if admitted to the Arctic area in the manner I suggest, would not get rid of this mass of ice There are however several important misconceptions and illogical deductions underlying the whole argument, and when these are exposed the results, however accurately worked out, become completely valueless

We first have it stated that if heat and cold were uniformly distributed over the Polar regions the whole would be permanently frozen over, and an ice-cap be formed of great but varying thickness, diminishing from the Pole to about lat 60°. But even this preliminary statement is open to serious doubt; for ice cannot be formed without an adequate supply of water, and over a large part of the Polar area no more snow falls than is annually melted by the sun and by warm southerly winds blowing over the heated land-surfaces of Asia and America. Admitting however that any such ice-cap could be formed, it would certainly not form in *one year* but by the accumulations of a long series of years , and any estimate of the *total* heat required to melt it has no bearing whatever on the *annual* amount that would be sufficient, since this depends solely on the average thickness of the ice *annually* formed, of which Prof. Haughton says nothing whatever.

The amount of rainfall in the Arctic regions (mostly in the form of snow) is certainly very small. It is estimated by Dr Rink to be only twelve inches in Greenland, and this is probably far above the average. All that falls on the inland plains of Asia, Europe, and America is however melted or evaporated by the action of the sun and air far from the influence of the Gulf Stream. The thickness of ice formed annually over the whole area of the Arctic Ocean I have no means of estimating In open water in very high latitudes it may be considerable, but perennial ice-fields can only increase very slowly. I should therefore very much doubt if the thickness of ice now formed annually over the whole Arctic area averages nearly so much as five feet , and Prof. Haughton himself calculates that our own Gulf Stream is now capable of melting this quantity

The first assumption, therefore—that the amount of heat required to be introduced into the Arctic regions in order to raise their mean temperature above the freezing-point is "accurately measured" by the amount required to melt an "ice-cap" covering the whole area to a thickness of several hundred feet—is grossly erroneous , and it is so because it takes the hypothetical *accumulated* effects of *many years* Arctic cold under altogether impossible conditions, and then estimates the amount of heat required to melt this whole accumulation in *one year* !

But we find a second and equally important error, in the assumption (involved in all Prof Haughton's arguments and figures) that all the ice of the alleged "ideal ice-cap" must be melted by that portion of the Gulf Stream which actually enters the Polar area, where its temperature is taken to be 35° F. or only 3° above the melting point of ice A large quantity of the Arctic ice, however, even now floats southward to beyond lat. 50° in both the Atlantic and Pacific, and is melted by the warmer water and atmosphere and the hotter sun of these lower latitudes. Now, as it is an essential part of my theory that much of Northern Asia and North America were under water at those early periods when warm climates prevailed in the Arctic regions, it is clear that whatever Arctic ice was then formed would have a freer passage southwards, and as the south-flowing return currents would then have been more powerful and more extensive than at present, a much larger proportion of the ice would have been melted by the heat of temperate instead of by that of Arctic seas

Prof. Haughton admits that the Kuro Siwo and the Mozambique currents together, if they entered the Polar seas, would be equal to the melting of a layer of ice more than thirteen feet thick over the whole area down to lat. 70°. But if our own Gulf Stream is sufficient to get rid of the whole of the ice that now forms annually—as Prof. Haughton's figures show that it would probably be, and as it would be still more certainly were Greenland depressed, thus ceasing to be the great Arctic refrigerator and ice-accumulator—then the heat of the other two currents would be employed in raising the temperature of the Arctic seas above

the freezing-point; and if we take the area of the water as about equal to that of the land, we shall have heat enough to raise the whole Arctic ocean to a depth of full 180 feet more than 20° F., or to a mean temperature of 52° F., and as this would imply a still higher surface temperature it is considerably more than I require.

Unless therefore Prof. Haughton can prove that the amount of ice now forming *annually* in the Polar regions is *very much more* than an average of five feet thick over the whole area, his own figures demonstrate my case for me, since they prove that the rearrangement of land and sea which I have suggested would produce a permanent mild climate within the Arctic circle and proportionally raise the mean temperature of all north-temperate lands.

Briefly to summarise my present argument:—Prof. Haughton's fundamental error consists in assuming that the true way of estimating the amount of heat required in order to raise the temperature of the Polar area a certain number of degrees is,—first, to suppose an accumulation of ice indefinitely *greater* than actually exists, and then to demand heat enough to melt this accumulation *annually*. The utmost *possible* accumulations of ice in the Arctic area, during an indefinite *number of years*, and under the most *adverse physical conditions* imaginable, are to be all melted in *one year*, and the heat required to do this is said to be the "accurate measure" of that required to raise the temperature of the same area about 20°, at a time when there were no such great accumulations of ice and when all the physical conditions *adverse* to its *accumulation* and *favourable* to its *dispersal* were immensely more powerful than at present!

When this fundamental error is corrected, it will be seen that Prof. Haughton's calculations are not only quite compatible with my views, but actually lend them a strong support.

ALFRED R. WALLACE

By the courtesy of Mr. Ingram I am enabled to say that the tree at Belvoir supposed to be *Araucaria Cunninghami* is in reality, as surmised by Capt. King, *Cunninghamia sinensis*. The *Cunninghamia* is a native of Southern China, whence it has been introduced into Japan. In this country it was originally grown under glass, but, as the instance at Belvoir illustrates, such protection is not absolutely requisite. The tree is however somewhat tender, and so far as I know has never produced its cones in this country in the open air.

As to the Bamboos hardy in this country, it may be well to warn those who are not familiar with the plants not to expect to see the gigantic and rapidly-growing grasses that go under this name in the tropics. Rarely indeed do they attain in this country the dimensions even of the *Arundo donax*, so familiar to travellers in Italy. As accuracy of nomenclature is proved in this and the foregoing instance to be a matter of much moment, it may be well to say on the authority of the late General Munro that the Himalayan plant commonly grown in gardens as *Arundinaria falcata* is more correctly called *Thamnocalamus Falconeri*, that the *Bambusa gracilis* of gardens is the true *Arundinaria falcata* of the Himalayas, and that the Japanese *Bambusa metake* is *Arundinaria japonica*. General Munro's monograph of this group is to be found in the twenty-sixth volume of the *Transactions* of the Linnean Society, part 1, 1868, while his remarks on the cultivated species may be found in recent volumes of the *Gardeners' Chronicle*, particularly in vol. vi. 1876, p. 773.

The simultaneous flowering of *Thamnocalamus Falconeri* a few years ago in all parts of Europe created much attention, and was indeed a remarkable illustration of hereditary tendency manifested under very varied climatal conditions. The flowering of this grass was by no means looked on with unmixed gratification, as it entailed as a consequence the death or protracted enfeeblement of the plant.

A visit to Kew or to any of our larger nurseries will suffice to show that there are other Bamboos (that is, grasses belonging to the group *Bambuseæ*, if not true Bambusas) which are hardy enough to withstand even such rigorous winters as those of 1878-9 and 1879-80.

MAXWELL T. MASTERS

Climate of Vancouver Island

THE letters on this subject which have appeared in NATURE (vol. xxiii. pp. 147, 169), have reminded me of a "Prize Essay on Vancouver Island. By Charles Forbes, Esq., M.D., M.R.C.S.Eng., Surgeon Royal Navy," which was published by the Colonial Government in 1862. It consists of sixty-one closely-printed octavo pages and eighteen pages of Appendix, the latter containing several Tables on the Meteorology of the Colony.

The following is a portion of the "Abstract of Meteorological Observations, taken at the Royal Engineer Camp, New Westminster, during the year 1861, by order of Col. R. C. Moody, R.E., Commanding the Troops. Lat. 49° 12′ 47″ N., Long. 122° 53′ 19″ W." (p. 3, Appendix):—

Max. temp. of air in shade at	9.30 a.m.,	July	9,	74.3° F.
" " "	3.30 p.m.	"		84.0 "
Mean " "	9.30 a.m.			48.8 "
" " "	3.30 p.m.			52.2 "
Min. " "	9.30 a.m.,	Jan.	21,	20.0 "
" " "	3.30 p.m.,	Dec.	23,	24.0 "
Min. temp. on grass on January 21				10.0 "

All the observations were made at 9.30 a.m. and 3.30 p.m. daily throughout the year.

WM. PENGELLY

Torquay, January 6

Dimorphic Leaves of Conifers

IT is now generally believed that some of the varying forms assumed by individual plants or animals in the course of their development are as it were the reflex of an ancestral state of things. From this point of view the different forms of leaves assumed by some Araucarias, as well as by many other conifers, become of particular importance. The Retinosporas now so common in our gardens and on our balconies represent an immature stage of some Thuya, the proof of which statement is occasionally furnished by the plants which suddenly assume the foliage characteristic of that genus. In various species of juniper, notably in the Chinese juniper, two forms of leaf representing the juvenile and the adult condition occur together on the same branch.

Assuming that the juvenile, or "larval" forms, as they have been called, do really represent previous conditions in the history of the species, it might be expected that some of the fossil coniferæ would be characterised by the possession of this larval foliage to the exclusion of any other. But if I mistake not both forms of foliage have been met with in fossil as in recent conifers, and the pedigree of these plants is by so much the more pushed back.

The resemblance in the form and arrangement of the adult leaves in some Thuyas and allied plants to the disposition of the leaves in Selaginella should not be overlooked in this connection nor the close resemblance between the foliage of some species of Lycopodium proper and the "larval" leaves of many conifers as above referred to.

MAXWELL T. MASTERS

Dust and Fogs

THE meteorological conclusions of Mr. Aitken's important paper, published in NATURE, vol. xxiii. p. 195, will, if adopted without further examination, even temporarily, exercise an unfortunate influence upon the present attempts to rid the atmosphere of our large towns of their ever-recurring fogs, glooms, and mists, and those conclusions certainly are not supported by such evidence as we already have as to the production of fogs on a great scale, however much indicated by experiments in the laboratory. It is stated that, "It having been also shown that all forms of combustion, perfect and imperfect, are producers of fog nuclei, it is concluded that it is hopeless to expect that, adopting more perfect forms of combustion than those at present in use, we shall thereby diminish the frequency, persistency, or density of our town fogs." Now, first as to frequency: what are the facts with regard to localities differing in their methods or materials for producing heat? Every one living in or near London knows that fogs, thick mists, and dark days are far more frequent within than without its circumference, and experiment has shown that sunshine is both less frequent and much less intense within the metropolis. And, according to Mr. Aitken's theory, something of the same kind ought to be observed wherever large quantities of fuel are burned, whether smokeless or not. Thus, the large towns of the Continent, where wood and charcoal are in general use, would have their peculiar urban fogs. But they are free from any fogs beyond those which are common to the country. And Paris, before coal was much used, ought to have been distinguished by more frequent fogs than the surrounding country. But it was not so marked out. No oasis of fog prevailed there when the sun shone brightly beyond its precincts, as in our own capital. And Philadelphia, which burns

anthracite, ought not to rejoice in a pure and transparent atmosphere.

Similarly, the South Wales coal and iron districts would be centres of fog clouds and mist, like Birmingham and Newcastle. But they are as free from fog as the purely pastoral valleys of Wales.

Next, as to persistency Early in the morning of January 31 last, in some districts of London the fog extended considerably above the tops of the houses, in others only about 10 or 20 feet from the ground in any intensity. Where the fog extended high the smoke mixed with it and produced a yellow fog, but where it remained low the smoke escaped into the upper air and drifted away, leaving a white fog below, so pure as to be a very unusual phenomenon at 10 a m in a London street Now it was remarkable, that wherever the white fog prevailed in the morning, the sun soon obtained the mastery and dispelled it more or less, but in the smoke obscured districts a dark yellow fog continued throughout the day

White fogs may doubtless be exceedingly dense But will not an admixture of smoke increase its density?

A humid atmosphere is not necessary for the production of mist and haze. The frequent long-continued prevalence of blue haze over the whole country, not excepting the east coasts, in the driest east winds of spring, would be a subject deserving investigation They sometimes extend to a height much above the tops of our highest mountains Experiments such as those of Mr Aitken will, we may hope, ultimately solve this problem of meteorology. R RUSSELL

Low Temperature

THE reading of the thermometer here last night, January 15, 16, was the lowest ever recorded at this observatory in the course of thirty three years The reading was 4°6 F, the previous minimum having occurred on December 24, 1860, when the mercury stood at 6° 7 F. S J PERRY

Stonyhurst Observatory, January 16

A "Natural" Experiment in Polarised Light

BREAK off a plate of ice and hold it between the sky and a pool of water. Its reflected image will show the beautiful colours due to polarised light The incident rays should come from a part of the sky about 90° from the sun, and reflection should take place at the polarising angle for water, and the plate will probably require adjusting to bring out the maximum effect Water, vaporous, solid, and liquid, thus furnishes us with polariser, crystal, and analyser I do not remember to have read any account of this very simple experiment, for which Nature provides all the materials. CHAS I. WHITMELL

9, Beech Grove, Harrogate, January 10

STATICS AND DYNAMICS OF SKATING

MANY years ago, when skating was but in its infancy, skates were made of bone, and if they could be made to stay on the feet they were considered to answer their purpose sufficiently well

More recently iron runners with wooden beds came into use, and accuracy of adjustment on the foot, horizontally and longitudinally, was made easier by means of leather straps and a screw passing into the heel of the boot, and these adjustments, made haphazard, were quite sufficient for the skating of those days, namely forward skating

Within the last twenty years however skating has made enormous strides, back skating becoming an essential qualification of a finished skater, and hence not only more perfect forms of skate are demanded from the maker, but also the adjustment of them on the boot becomes an important part of his duty.

There are three points to be attended to in the adjustment of the skate, besides the obvious one of placing the skate medially on the foot.

1 Height of foot off the ice where the greatest breadth of the sole of boot occurs

2 Height of foot off ice at the heel

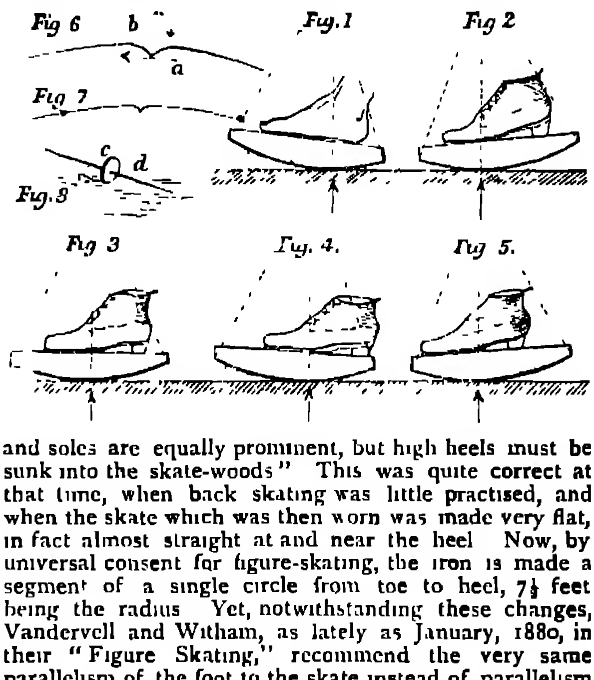
3 Position of the skate longitudinally or lengthwise on the foot

First. The height of the foot from the ice should be such as will enable the skater to lean over sufficiently when on a curve, and such that he may be able to get a powerful enough stroke If he is too low the edge of the boot will come in contact with the ice in leaning over and also in taking a stroke, a fall ensuing in the first case, and a disagreeable and dangerous overstrain in the second To avoid these the sole of the boot should subtend an angle at the bottom of the runner of about 96 deg *i e* for a sole 3½ inches broad the edge of the runner should be 1½ inch from the sole, instead of varying from 1⅞ to 1⅛ inch, which are the heights of skates commonly met with

This angle of 96 deg will be found to clear the ice in both striking and leaning over for most skaters, and any greater height than is given by this angle should not be used, as it is not necessary, and only throws an additional strain on the ankle

Second The height at the sole having been fixed, the next point is what should be the height at the heel? In fact is the foot to be parallel to the skate, or is it to rest on an incline?

Dove was the first person, in his "Skater's Monitor," published in Edinburgh in 1846, to write on the position of the skate on the foot, summing up his remarks by saying, "Level woods then are for shoes whose heels



and soles are equally prominent, but high heels must be sunk into the skate-woods" This was quite correct at that time, when back skating was little practised, and when the skate which was then worn was made very flat, in fact almost straight at and near the heel Now, by universal consent for figure-skating, the iron is made a segment of a single circle from toe to heel, 7½ feet being the radius Yet, notwithstanding these changes, Vandervell and Witham, as lately as January, 1880, in their "Figure Skating," recommend the very same parallelism of the foot to the skate instead of parallelism of the top of the blade to the ice, as it should be for modern skating, as I shall subsequently show

In Fig 1 is shown the result of adopting Dove's or Vandervell and Witham's position, *i e* no heel It might be thought that a person standing on a curve would balance comfortably at the middle of the curve, but this cannot be, for a person standing naturally on a level surface does not distribute the weight of his body equally over the length of his foot, but by far the greater part comes on the heel, and therefore the centre of pressure of his body is nearer the heel than the toe, and consequently if he is standing on a curve the curve must roll up in front and down behind till the upward pressure of the ice just passes through the centre of pressure of his body The point of contact of the skate on the ice will therefore not only be much behind the centre of the skate, but will be a little behind the centre of pressure of his body when standing on a level surface, as he now

rests on an incline Of course the footstocks of the skates being too low behind would produce the same effect as too low a heel to the boot, *i.e.* throw the balance too far back

Fig. 2 shows the position the skate will have on the ice if the heel is too high, *i e* the centre of pressure is thrown too far forward, and consequently the skate must roll up behind in order to get the proper balance

In Fig 3 is shown a skate in the proper position on the ice, *i.e* with the heel raised so high as to throw the centre of pressure on the centre of the foot and skate

The proper height of the heel of the boot to obtain this result will depend on whether the footstocks of the skates are level, as they ought to be, and the exact height will vary with different individuals, depending on whether they naturally stoop or lean well back, and probably also on the boots they are in the habit of walking in, and therefore can only be determined accurately by trial, but a half-inch heel is by no means too low for most persons

Third With regard to the adjustment of the skate longitudinally, Figs 4 and 5 will show the obvious effects of not fixing the skate properly on the foot, in Fig 4 the skate being put too far forward, and in Fig 5 too far back

Having now shown how to procure the balance on any desired part of the skate, it only remains to be shown why the position of the skate, with the balance on the centre as in Fig 3, is the proper one, and as the effects of the various positions are most evident in skating turns, I shall confine myself entirely to them, commencing by giving the theory of turns, which I believe has never been satisfactorily explained

It is impossible in a few words to describe accurately and fully the forces which come into action in making a turn, but my object will be attained by describing what I consider the basis of the whole theory of turns, namely, that a turn is not a twist round of the body made by the skater at the moment of the turn, but the turning round of the body is the result of a reaction of the ice on the skater caused by his putting his skate (by rolling on to the toe or heel) in such a position as to make that part of the skate bite or grip the ice, producing a force opposite, though not directly opposed, to his direction of motion, but parallel to it The direction of this reaction is shown by the arrow *a* in Fig 6, and being exerted at some distance from the body, it necessarily tends to turn the body round in the direction of the arrow *b* It will be evident that the greater the distance of the point of application of this force from the curve the skater is describing, the greater will be the *couple* tending to turn round the body

This action can be shown by means of a disk of lead *c*, in Fig 8, with a light rod through it If this be made to roll on a table, and a force be applied to the rod at *d* by means of the finger, the action of reversing the body and preserving the same inclination will be distinctly shown Suppose the skater then about to make a back turn, and that he balances near the heel of his skate as in Dove's plan, then, as he can only roll a very little further back, as he is already on the heel of his skate, the leverage, and hence the couple tending to turn him round, will be almost *nil*, the cusp he makes being of the shape shown in Fig 7, instead of being of the shape shown in Fig 6, and consequently if he is to turn round in time he must give his body a wrench round, which is of course very inelegant, and very difficult to accomplish. If the balance is on the heel the cusps of the forward turns are much larger than the cusps of the back turns, thereby tending to make the back turns more difficult than is necessary, but even with the balance on the centre of the skate back turns will be more difficult than forward turns, as the formation of our bodies prevents the bending up of the foot more than a few degrees, even with a boot off, whereas we can bend it down 40 deg easily

With the balance on the centre of the skate back turns can be performed without any wrench or swing of the leg—a thing that is physically impossible if the balance is on the heel, as it must be in Dove's or Vandervell and Witham's plan. CHARLES ALEX STEVENSON

JOHN DUNCAN THE ALFORD WEAVER AND BOTANIST

ON the last day of 1880 the University of Aberdeen was presented with a herbarium of 1131 specimens of the British Flora, gathered, preserved, named, and localised by an aged country weaver who lives near Alford in Aberdeenshire He is no ordinary man, as the accumulation of such a botanical collection is alone sufficient to prove It represents a portion only of the scientific labours of nearly fifty years --for much of these have been destroyed by time and the moth This remarkable man, who is now a pauper on the parish which has been the scene of his unextinguishable scientific enthusiasm, should be better known to the scientific world, and a short sketch of his life and labours may not be unacceptable to the readers of NATURE.

John Duncan was born on December 24, 1794, so that he is now in his eighty-seventh year His parents were very poor, and could afford him only the merest rudiments of even the three R's as then taught, for his education had to be sacrificed to the pressure of penury He learnt to read by laboriously spelling his way through the text in church, his writing has ever been very rude, but distinct, and his spelling is such an example of the phonetic as would delight Mr Pitman He was early sent to work and became a "customer weaver," making into cloth the flax and wool sent to his home by his neighbours, and such he has remained ever since He married early in life, and had a son and two daughters, but his wife died more than thirty years ago, and all his family have gone, he remaining as the sole survivor During the greater part of his long life he has dwelt in the valley of the Don, near Alford, and for nearly thirty years in the same cottage at Droghsburn, in the pleasant hollow of the Leochel, five miles above that village This cottage forms one end of a line of dwellings, the other belonging to a ditcher's family who prepare his simple meals He occupies a single room, filled with the looms and other implements of his trade, open to the thatched roof, his bed resting on some deals laid across the rafters, and reached by means of a ladder In this narrow space John Duncan has lived for twenty-eight years, a solitary man, in serene contentment, upright and religious, working laboriously for an honest living, cheered only by the friendship of a few, his love of books and his devotion to the study of plants, which he has prosecuted with a single-minded enthusiasm that is as rare as it is beautiful. I visited him about three years ago and spent two days in his company, having long wished to do so from what I had heard of him from his dearest friend and fellow student, Charles Black I found him in good health, working hard at his craft with sturdy and admirable independence, visited only by a few disciples whom he had inspired with a love of himself and the plants, unknown, self-contained, and happy even on the verge of want I examined his plants, talked of their history and the crowding memories they recalled of countless wanderings in their search saw his books on botany, theology, and general literature, which are unusually numerous and costly for a poor man, conversed with him on many subjects, chiefly connected with his studies, and his intimacy with Charles, whose friendship is now the chief comfort of his age, and I left him charmed, inspired and rebuked by his life, character, enthusiasm and wise contentment, the result of unwearied devotion to higher pursuits

Some interest in the solitary student was roused by an

account I then gave of him. This account appeared in *Good Words* for April, May, and June, 1878, with pictures of himself and his cottage. It has recently been incorporated in whole into "Leaders of Men," by H. A. Page (Marshall, Japp, and Co., London), and he was visited by not a few kindly spirits whose open-handedness lightened somewhat the growing pressure of age and want. Since then he has worked at his loom, winning his daily bread with heroic struggle, till a short time ago, when decaying power and some paralytic touches, in his eighty-sixth year, compelled him reluctantly to give it up and remove from his small but honourable workshop and study to be kindly tended by the ditcher's widow. Many years ago his hard-won earnings—for he was always a most careful man—were dissipated through domestic causes over which he had no control, attended with heavy griefs. Since then his growing age has barely enabled him to live more than from hand to mouth, and now for some time he has had to do what must be inexpressibly keen to an independent soul like his, to accept from the parish a pauper's portion.

From his earliest days, when he used to play upon the green cliffs of the high conglomerate coast of Kincardine, John Duncan had an intense love of plants, and long before he began their scientific study collected them for their medicinal uses, guided by Culpepper's "Herbal." It was not till he was forty years of age, when he was introduced in 1835 to Charles Black, that he commenced the study of botany as a science. Charles was a remarkable man, of great individuality and ability, and though twenty years his junior, at once gained over him an ascendency of the best kind, and inspired him with an ardent friendship that has been the sweetest solace of his long solitude. He still lives as the gardener he was then, a botanist, geologist, ornithologist, numismatist, scientific student, theologian, and omnivorous reader at Arbigland in Dumfries, near the mouth of the Nith. When these two men met, Charles was settled as gardener near Alford, and under his guidance John at once began the systematic study of botany. They soon conquered the flora of the Vale of Alford, the curious peak of Ben-a-chie, where they found at an early date the *Rubus chamæmorus*, or cloudberry, being a favourite haunt. John, having his time, as a home weaver, more at his own command, by and by extended his excursions to greater distances, and before very long did the most of the county. The enthusiasm with which these two humble men prosecuted their studies was wonderful, the morning light often surprising them at their work of classifying, drying, and arranging their accumulating treasures. The want of text-books of the science was sorely felt by them, and excited them to ingenious devices to supply it; a certain country inn, for example, being frequented by them, not for convivial purposes, but to obtain a sight of "Hooker," which had belonged to the innkeeper's dead son. The details of John's continued studies under poverty, difficulty, and trial are interesting and honourable, but these cannot be given here. In order to extend his knowledge of botany and the flora of Scotland he used to take harvest work in different parts of the country, studying in succession the plants of each district, till he had in this way traversed the most of the land from Northumberland to Banff, except some parts of the West and the Highlands; bringing home specimens living and dead, planting the one in his own neighbourhood, and adding the other to his rapidly-increasing herbarium. His knowledge of plants was minute and scientific, and the abundant technical terms were used with ease and intelligently understood by the help of a Latin dictionary he had purchased for the purpose; nor was it confined to mere technicalities, but extended to an unusual acquaintance with their habits, history, and uses. His collection of botanical works is surprisingly large and valuable, all purchased by his own hard-won earnings. His memory being as strong as his use of the pen was weak, he did not write down any details of the plants thus collected, but he could tell all these when asked with unerring precision, as well as relate the varied incidents, interesting, humorous, happy or hard, connected with their discovery. The names and localities have however been successfully obtained from him and written down, by the help of one of his disciples, Mr. J. M. B. Taylor, of Aberdeen, who prepared the herbarium for the University.

John kept his collection neatly laid down in volumes made by himself of newspapers of the period, of tea paper, which he thought a good protection against moths, and of other homely materials scented with camphor. Many of them of course decayed or were destroyed during the forty and more years they were in his possession, but even after discarding all imperfect specimens there remained 1131 plants now fully named, localised, and arranged by Mr. Taylor from John's unfailing memory. They are divided in four books, put together by John himself.

1. A general collection of some 500 specimens including ferns arranged according to the Linnæan system, 100 of which are described by Prof. Dickie, author of the "Flora of Aberdeen, Banff, and Kincardine," as rare or very rare.

2. An almost perfect collection of the flora of the Vale of Alford, many of the plants now uncommon.

3. Specimens of about 50 of the grasses from the Alford district.

4. Specimens of some 50 of the Cryptogamia of the district, chiefly mosses and lichens.

John never possessed above a few of *the very rarest* of our British plants, not having visited the higher mountains and outlying regions where only such are found, but had been fortunate in obtaining a large number of local and very local, rare and very rare species. They were mainly found along the eastern half of the country from Banff to Northumberland, excluding the Highlands.

Such is a very slight sketch of the life and labours of this remarkable weaver. The presentation of his herbarium has revealed the sad fact that, independent and toil-worn as he has ever been, even to nigh eighty-six, he has been lately compelled to bear the pain and shame of depending on the parish for his daily bread. His books are of value, and would alone fetch a considerable sum, but these, the dear companions of his life, he cannot bring himself to part with, though now unable to enjoy more than a sight of them. His beloved plants he would not barter for heaps of gold, and he has therefore presented them to Aberdeen University, there, it is to be hoped, not only to do good educational work, but to exercise an inspiring impulse over many generations of students privileged to examine these far-fetched treasures.

An appeal has recently been publicly made in favour of the aged botanist, to enable him to spend his few remaining days in comfort and independence, supported by the free-will offerings of the scientific and generous, which have been amply won by scientific work admirably achieved. Scientific societies throughout the country could not better aid research than by recognising his merit, and making a contribution for such a worthy object. Shortly after my account of him in *Good Words* the Largo Field Naturalists' Club elected John an Honorary Member, and the same has been recently done by the Inverness Scientific Society and Field Club, which also made a donation to him of 5*l.*, examples that might be honourably followed by other societies. A lively interest has been excited in his case, and has been already substantially expressed. It is devoutly to be hoped that such a man will not be allowed to go down to his grave dishonoured and neglected.[1]

THE INDO-CHINESE AND OCEANIC RACES—TYPES AND AFFINITIES[1]

IV.

HERE are the Raja of Gorontalo, N. Celêbes (Fig. 22), the chief of Sendegeassi, S. Nias, West Coast Sumatra (Fig. 23), and two natives of Jilolo (Fig. 24), all supposed to be more or less typical Malays whom it will be profitable to compare with Figs. 19, 20, 21, representing the Caucasian pre-Malay or Indonesian element in the Archipelago. In Fig. 25 we have Mohamed-Yamalal-Alam, Sultan of the Sulu Archipelago who was compelled to accept Spanish supremacy in 1876. He is a pure Malay about thirty-four years old, like most of his subjects presenting a fine type far superior to that of the Malays of Malacca. Yet the Mongoloid element is unmistakably betrayed, especially in the high cheek-bones, presenting such a striking contrast to the regular European features of the Indonesians (see Figs. 19, 20, and 21). The portrait is from a photograph forwarded to France by MM. Montano and Rey, and originally published in *La Nature*, April 3, 1880.

But if we must speak with great hesitation and much reserve of a common Malay type, we can speak all the more confidently not only of a common Malay speech, but of a common "Malayo-Polynesian," and even of a common Indo-Pacific speech. Indeed the chief objection to the linguistic expression Malayo-Polynesian is that it is no longer sufficiently comprehensive. In the alternative Indo-Pacific, which, on the analogy of Indo-European, I have proposed as a substitute, the first component must be taken in two senses, so as to include both the Indian Ocean and a portion of Further India. When Fr. Muller wrote: "So much remains certain, and will never by the most brilliant and cogent reasonings be disproved: the Malayo-Polynesians are connected with no Asiatic people," he had in his mind not so much the "Malayo-Polynesian race" as the Malayo-Polynesian language. In this sense the statement was true enough according to his lights. In common with other eminent philologists he entirely overlooked Cambojan, or from insufficient data probably regarded it as a monosyllabic-toned language allied to the Indo-Chinese family. He consequently considered it as fundamentally distinct from the Malayo-Polynesian group, which is admittedly polysyllabic and untoned. But we have already seen in Section IV. that Cambojan or Khmêr is not a member of the Indo-Chinese family, and that it is polysyllabic and untoned, like all other known forms of speech. In the above-quoted paper "On the Indo-Chinese and Inter-Oceanic Races and Languages" (pp. 15-22) I further show that the true affinities of Khmêr are with the Malayo-Polynesian tongues, the whole forming a vast linguistic family stretching from Madagascar to Easter Island, west and east, from Hawaii to New Zealand, north and south, and with its basis still resting on the Indo-Chinese peninsula, where it originated, and whence it has been diffused throughout the Oceanic area with the migrations of the Mongolo-Caucasian races. Here it has long reigned supreme, continually encroaching upon and surrounding, as in so many detached enclaves, the diverse Negrito and Papûan tongues, but itself now threatened with extinction by the advancing Siamese and Annamese on the mainland, and by the still more aggressive English in Polynesia.

All the arguments establishing the intimate connection of the Cambojan and Malayan languages need not be repeated; but that based on the principle of modifying infixes has attracted so much attention, and is in itself so interesting, that the readers of NATURE will perhaps be glad to have it here resumed:—

"Common to the Khmêr and Malaysian tongues is one feature so peculiarly distinctive as of itself alone almost sufficient to establish their common origin. This is the use of identical infixes, which, though forming a marked characteristic of Khmêr, Malay, Javanese, Tagala, Malagasy, and other members of this group, has not yet been generally recognised. . The infixes in question are always the same, the liquids *m* and *n*, and even *mn*, with or without the connecting vowels *a*, *o* with *m*; *a*, *i* with *n*. Thus:—

IN KHMÊR: *m, am, om, mn, n*.

Slap, dead; samlap, to kill.
Sruoch, pointed; samruoch, to point.
Thleak, to fall; tomleak, to throw down.
Rolôm, to fall; romlom, to knock down.
Chereap, to know; chumreap, to show, teach, make known.
Kur, to draw; Komnur, a design.
Srek, to cry; samrek, a shout.
Chêk, to share; chamnek, a part or portion.
Sauk, to corrupt; samnauk, a bribe.
Pram, to publish; bamram, a notice.
Pang, to wish; bamnang, a wish.
Rep, to confiscate; rombep, seizure, thing seized.
Ar, to saw; Anar, a saw.

IN MALAGASY: *in, om*.

Hanina, food; homana, to eat.
Tady, twisted, a rope; tamady, strong.
Taratra, glaring; tomaratra, transparent.
Safotra, overflown; somafotra, brimful.
Sany, likeness; somany, like.
Safy, spying; somafy, sight of distant object.
Vidy and vinidy, bought.
Vaky and vinaky, broken.

IN MALAYSIAN: *um, âm, in*.

Javanese.

Rayah, to bereave; rinaya, to be bereft.
Hurub, flame; humurub, to flame.
Balinbin, a small fruit; binalinbin, a round gem.

Tagala.

Basa, to read; bumasa, to make use of reading.
Kapatir, brother; kinapatir, brotherly.
Tapay, to knead; tinapay, bread.
Guntin, shears; gumuntin, to cut with shears.

Malay.

Palu, to beat; pâmalu, a club.
Pukul, to strike; pâmukul, a hammer.
Sipit, to grasp; sinipit, an anchor.
Padam, to extinguish; pâmadam, an extinguisher.
Pilih, to choose; pâmilihan, choice" (pp. 20-1).

This characteristic, of which nothing but the faintest echoes occur in any other linguistic system, is obviously one that is incapable of being borrowed, as prefixes and suffixes may occasionally be borrowed. Hence it must be regarded as an organic principle developed in the primitive speech before its differentiation into the various Oceanic branches, whose common origin seems thus to be established beyond question. The theory of such a remarkable feature being evolved independently at several points in this linguistic area and in no other cannot be seriously entertained.

Here therefore we have one type of speech everywhere common to two racial types, and the question arises, how all the Malayan peoples have come to speak exclusively polysyllabic untoned tongues, while their nearest kindred, the Mongoloid peoples of Indo-China, still speak exclusively monosyllabic toned languages. To explain this phenomenon we must remember that, as already pointed out, the polysyllabic-speaking Caucasians preceded the monosyllabic-speaking Mongols both in Farther India and in the Archipelago. Hence when the Mongols quitted the mainland they found the islands occupied by the Caucasians, with whom they amalgamated, and whose speech they adopted. Similar instances, though perhaps not on such a large scale, have occurred often enough elsewhere, even in historic times. Thus the Mongolo-Tatar Aimaks and Hazaras of North Afghanistan all now speak

[1] Continued from p. 251.

Persian; the Ugro-Finnic Bulgarians have been Slavonised in speech since the tenth century; the Northmen of the Lower Seine valley entirely forgot their Norse tongue within two generations, and many of the early English settlers in Ireland rapidly became "Hiberniores ipsis Hibernicis," more Irish than the "Irishry" themselves. Special causes, arising from the utterly antagonistic nature of toned and untoned languages, must have accele-

FIG. 22.—Malayan Type, Celebes. King of Gorontalo.

rated the process of assimilation in Malaysia, where nevertheless its universality still remains a remarkable circumstance. For it is undoubtedly surprising that not a single Malay community should have succeeded in retaining its original monosyllabic speech, and still more surprising to find that every trace of monosyllabism had already disappeared, at least from Java, Madura, and Bali some two thousand years ago. The old Kawi language current in those islands and reduced to writing by the Buddhists at that remote period is as genuine a polysyllabic tongue as its modern representatives, Javanese, Sundanese, Madurese, and Balinese.

The eastern or Sawaiori branch differs greatly from the

FIG. 23.—Malayan Type, Sumatra. Chief of Sendegrassi, Nias Island.

western or Malaysian, with which it has now really little in common beyond the fundamental elements. But these, after a separation of probably many thousand years, are still numerous enough to establish beyond all doubt their primeval unity. In this instance, however, as in so

FIG. 24.—Malayan Types, Jilolo. Mother and Daughter, Dodinga.

many others, community of speech in no way involves community of descent, for we have just seen that the language now spoken by the Malay races was in all probability imposed upon them by their Caucasian predecessors in the Archipelago. On the other hand there is no reason to suppose that the Eastern Polynesians ever spoke any other than their present language, its resemblance to the Malay being due not to their relationship with the Malay people, but with the Indonesian Caucasians, from whom the Malays borrowed their speech.

Like the other members of the family Sawaiori is agglutinating, but it occupies a very primitive or undeveloped position in that order of speech. Thus it betrays very slight traces of the infix principle, but it possesses as a prefix the same particle *ma*, which in Cambojan and its Malaysian congeners appears as an infix. In Samoan, for instance, *fai* = to do, but *mafai* = to be able, *sasa'a* = to spill, *masa'a* = spilt; *lilgi* = to pour out, *maligi* = to be poured out; *fasi* = to split, *mafasi* = to be split off, *fati* = to break, *mafati* = to be easily broken, *fola* = to spread out, *mafola* = to be spread out, *gaegae* = to shake, *māgaegae* = to be loose; *goto* = to sink, *magoto* = to be sunk or waterlogged, and so on, generally in an intransitive or passive sense.
